 — Portuguese, mortality in, 11  
 Arnold's enema-apparatus, 235; surgical bag, 327  
 Arnott, Mr. H., treatment of cervical abscess, 727  
 Arsenic in wall-papers, 101, 392; in menorrhagia and leucorrhœa, Dr. Aveling on, 247; in chorea, Dr. J. K. Spender on, 429  
 Arteries, variations in diameter of, 703  
 Artery, axillary, Dr. Smart on injury of, causing gangrene, 245, 542; central, of retina, Mr. C. S. Jeaffreson on embolism of, 351; popliteal, aneurism of, 383, 439, 729; innominate, aneurism of, 387, 653; vertebral, Mr. H. Taylor on embolism of, 527; subclavian, ergotin injected in aneurism of, 529; aneurism of, 686  
 Artery-forceps, self-holding, 597  
 Artesian well, an, 703  
 Arthritis, chronic rheumatic, 557  
 Asbury, Mr. J. V., obituary notice of, 195  
 Ascites, elaterium in, 557  
 Aspray, Mr. C., obituary notice of, 279  
 Asuaftida, syrup of, 670  
 ASSOCIATION, BRITISH MEDICAL, Mr. Gamgee's remarks on, 20; programme of annual meeting, 21, 48, 77, 106, 131, 159; proposed alterations in laws, 22, 48, 133; committee on Parliamentary Bills, 22, 134; collection of subscriptions, 42; annual museums, 46, 48, 78, 391; statement of local committee, 77; secretaries of sections, 78; Mr. Hodgson on the business of, 137; president's address, 169; address in medicine, 171, 219; report of committee on Observation and Registration of Disease, 177; report of Parliamentary Bills Committee, 178, 212; report of Poor-law Committee, 179; remarks on the annual meeting, 182, 215, 265; thirty-ninth annual meeting, 189, 200; address from Town Council of Plymouth, *ib.*; vote of thanks to the retiring president, *ib.*; report of Council, 190; financial statement, 191; discussion on report, *ib.*; report of joint committee in the report of the Royal Sanitary Commission, 203, 212; members present at annual meeting, 208; discussion on alterations of laws, *ib.*; address from Town Council of Devonport, 210; place of meeting in 1872, *ib.*; report of Medical Reform Committee, 210; votes of thanks, 213; dinner, *ib.*; meetings of Committee of Council, 214, 536; address in surgery, 225; remarks on business and constitution, 236; photographs of members, 240; Section of Medicine, abstract of papers and discussions, 241; Section of Surgery, abstract of papers and discussions, 243; Section of Midwifery, abstracts of papers, 244; Section of Public Medicine, abstracts of papers and discussions, 247, 274; members of committee of Council, 250; temperance breakfast, *ib.*; excursions, 251, 311; members of joint committee on Sanitary Legislation, 276; members of Poor-law Medical Reform Committee, *ib.*; arrangements for meeting in 1872, 311; election of general secretary, 533; Mr. G. May on memorabilia in history of, 575; preparations for the annual meeting in 1872, 731; list of officers and council, 763; list of members, 765  
 — Bath and Bristol Branch, annual meeting, 164; ordinary meetings, 569, 740  
 — Birmingham and Midland Counties Branch, annual meeting, 23; general meetings, 510; meetings of pathological and clinical Section, 564, 681  
 — Cambridge and Huntingdon Branch, annual meeting, 49  
 — Cumberland and Westmorland Branch, annual meeting, 161; autumnal meeting, 593  
 — East Anglian Branch, annual meeting, 49  
 — Lancashire and Cheshire Branch, annual meeting, 80  
 — Metropolitan Counties Branch, annual meeting, 162  
 — North Wales Branch, annual meeting, 108  
 — Northern Branch, annual meeting, 48  
 — Reading Branch, annual meeting, 536  
 — Shropshire Ethical Branch, annual meeting, 536  
 — Shropshire Scientific Branch, annual meeting, 632  
 — South-Eastern Branch, annual meeting, 78; East Kent district meeting, 681; West Kent district meetings, 450, 681; East Sussex district meetings, 423, 681  
 — South Midland Branch, autumnal meeting, 451  
 — South Wales and Monmouthshire Branch, annual meeting, 135; autumnal meeting, 594  
 — West Somerset Branch, annual meeting, 134; autumnal meeting, 450  
 — Yorkshire Branch, annual meeting, 164  
 Association, British, for advancement of science, annual meeting, 187, 225; suggested changes in, 216  
 — of Certifying Medical Officers, annual meeting, 656  
 — Herefordshire Medical, report of, 421  
 — Italian Medical, programme of, 445  
 Association, Manchester and Salford Sanitary, discussion on small-pox, 74  
 — of Medical Officers of Health, proceedings of, 538, 653, 787  
 — proposed medical, in Spain, 332  
 — North of Scotland Medical, annual meeting, 157  
 — Poor-law Medical Officers of England, annual meeting, 126; meeting on Mr. Corrance's Bill, 562; payment of subscriptions, 655; address, 744  
 — Poor-law Medical Officers of Ireland, address, 745  
 — St. Andrew's Medical Graduates, summer session, 73; annual session, 678  
 — Social Science, subjects for discussion in, 238  
 — proceedings in department of Public Health, 476  
 Asthma, cardiac, digitalis in, 92; Dr. Anstie on pathological relations of, 550; Dr. Thorowgood on, 612  
 Asylum, for idiots, at Lancaster, 156; new, for East London, 184; lunatic, at Aberdeen, 220; for idiots, at Earlswood, donation from Queen to, 386; new, in Glasgow, 620  
 Asylums, remarks on management of, 12, 100; superannuation of medical officers of, 47; letter on management of, 109, in England, statistics of, 387; of Victoria, 672  
 Atlas, Mr. W. Stokes on gunshot fracture of, 716  
 Australian meat, 218, 648, 650; entozoa, 590  
 Aveling, Dr. J. H., arsenic in menorrhagia and leucorrhœa, 247  
 Axford, Mr. W. H., vaccination, 135  
  
**B.**  
 Baby-farming in Scotland, 18; proceedings of committee concerning, 103; trial concerning, 156, 360  
 Baker, Mr. Benson, poor-law medical service, 249; sanitary tour through Dublin, 335, 362; medical charities of Ireland, 507, 565  
 Barbosa, Dr., Operations at St. Joseph's Hospital in Lisbon, *rev.*, 11  
 Barham, Dr. C., the annual meeting of the Association, 83; diseases of miners, 241, 253  
 Barnes, Dr. R., sudden death in patients suffering from cancer, 63; hypertrophy of the cervix uteri, 246, 375; decapitation and evisceration, 570; investigation of diseases of women, 578  
 Barry, Mr. T. S., obituary notice of, 711  
 Barton, Dr., treatment of ganglion, 123; introductory lecture at the Adelaide Hospital, 592  
 Basham, Dr. W. R., introductory address at Westminster Hospital, 412  
 Bastian, Dr. H. C., epidemic and specific contagious diseases, 400  
 Bathes, sea-side, safety for, 268  
 Baths, new, at University College Hospital, 186; public swimming, 331  
 Battery, portable galvanic, 281  
 Bäumlér, Dr. C., idiopathic pericarditis, 484  
 Beatty, Dr. T. E., fibro-cystic disease of the uterus, 246, 517; radical cure of retroflexion of uterus, 246, 341  
 Beauprethuy, Dr., death of, 421  
 Beer, chloral in, 618  
 Begbie, Dr. J. W., therapeutic action of turpentine, 277  
 Behrend, Dr. H., lip-reading by the deaf and dumb, 698  
 Bell, Dr. Joseph, treatment of ganglion, 95; treatment of scrofulous abscesses of neck, 728  
 — Mr. Royes, treatment of ganglion, 9  
 Belladonna, poisoning by, 326  
 Bellamy, Mr. E., treatment of ganglion, 37; treatment of scrofulous abscesses of cervical glands, 757  
 Bennet, Dr. J. H., physical geography and climate of Spain, 346  
 Bequests, 131, 224, 339, 353, 372, 424, 441, 515, 588, 572, 581, 622, 656, 677, 713, 747, 790  
 Berlin, special correspondence from, 24, 193, 623, 784  
 Bernays, Dr. A. J., disinfectants, 364  
 Bigelow, Dr. A., on dislocation of the hip-joint, 718  
 Billroth, Dr., Surgical Pathology, *rev.*, 11; ovariectomy, 650  
 Birt, Mr. J., obituary notice of, 367  
 Black, Dr. D. C., treatment of nocturnal enuresis, 609  
 Blackman, the late Dr. G. C., 388  
 Bladder, exfoliation of, Mr. Spencer Wells on, 8; Mr. W. Whitehead on, 432; Dr. G. Buchanan on, 520  
 Dr. Althaus on paralysis of, 242, 581; hyperæsthesia of, 379; extroversion of, 585; Sir H. Thompson on diagnosis of diseases of, 662  
 Blandford, Dr., Insanity and its Treatment, *rev.*, 327  
 Blood, heat of, during arterialectomy, 222  
 Blunt, Mr. T. P., disinfectants, 61  
 Bones, removal of tumours from, 50

Bone-setter, a female, 618  
 Bone-setting in Algeria, 649  
 Boulton, Dr. P., treatment of retroflexion of the uterus, 524; paralysis during pregnancy, 756  
 Brabazon, Dr. A. B., pathology and treatment of cholera, 278; treatment of retroflexion of the uterus, 539  
 Bradbury, Dr. J. B., prognostic value of hæmoptysis, 259; treatment of cholera and diarrhoea, 383  
 Bradley, Mr. S. M., new evolutions of disease, 19; unity of syphilitic virus, 246, 376; the germ-theory of disease, 452; rupture of membranes before delivery, 612; death in chloroform-poisoning, 641; effect of rocking on temperature, 725  
 Brain, Dr. G. Gray on decreased frequency of pulse as a sign of disease of, 94; digitalis in anaemia of, 147; cancer of, 603; concussion of, 681; iodide of potassium in disease of, 653, 684; tumour of, 710  
 Bramwell, Dr. J. B., address to Northern Branch, 49  
 Brazil, Emperor of, visit to College of Surgeons, 128  
 Breast, cancer of, 604, 608  
 Broadbent, Dr. W. H., chloral in delirium tremens, 36; herpes frontalis giving rise to erysipelas, 94  
 Bromide of potassium, effects of, 340, 352, 353, 350, 426, 435  
 Bromine in uterine cancer, 246  
 Bromohydrates of quinine and cinchonine, 501  
 Brown, Mr. G. D., abdominal puncture in tympanites, 526  
 — Dr. J. D., on death from chloroform, 93  
 — trust and the University of London, 14, 55  
 Browne, Dr. Henry, treatment of cholera and diarrhoea, 381  
 — Dr. J. C., hysterical mania, 113, 145  
 Browning, Mr. B., recovery after swallowing a large quantity of chloral, 640; rupture of aorta within pericardium, 661  
 Brumwell, Dr., hydrophobia after bite of a cat, 434  
 Bruntton, Dr. T. L., experimental researches on the action of medicines, 659, 687, 749  
 Buchanan, Dr. G., treatment of ganglion, 95; exfoliation of the bladder, 520  
 — Dr. R., obituary notice of, 453  
 Bucknill, Dr. E., amaurosis after convulsions during bronchitis, 756  
 Bullen, Mr. G., obituary notice of, 629  
 Bunton-spring, a, 441  
 Burns, treatment of, 203  
 Burrows, Mr. Cordy, testimonial to, 503  
 Bushell, Mr. T., obituary notice of, 433

## C.

Cabs, small-pox in, 620  
 Cacography, ingenious, 746  
 Cæcum, cancer of, 670  
 Calabar bean, poisoning by, 73  
 Calculi in Museum of Royal College of Surgeons, Mr. T. Taylor's Catalogue of, rev. 500; under the prepuce, 730  
 Calculus, rare, 193; in female bladder, Mr. C. Heath on, 431; large, with tumour of prostate, 558  
 Calvert, Dr. C., antiseptics and disinfectants, 140  
 Campaign, the Berkshire, 155  
 Canal, the Regent's, state of, 242  
 Cancer, Dr. R. Barnes on sudden death in, 62; treatment of by condurango, 237, 309, 497, 503, 734; of stomach, 527, 597; of kidney, 583, 597; of brain, 603; of spleen, 604; of breast, 604, 609; intrauterine, 634; of oesophagus, excision of, 643; of cæcum, 670; rapid formation of, 686; of mediastinum, 742  
 Cancerum otis, Dr. Priestley on, 577; Mr. McGreevy on, 635  
 Cane-sugar, action of light on, 704  
 Cantharides, poisoning by, 497  
 Capillaries, action of digitalis on, 27  
 Carbolic acid in snake-bite, 70; Dr. A. Mackintosh on experiments with, 161; vegetable source of, 569; in small-pox, 611; paper, 790  
 Carmichael, Dr. J., rare luxation of ankle, 35  
 Carpenter, Dr. A., sewage and entozoa, 627, 711  
 Carter, Dr. W., introductory address at Liverpool Royal Infirmary School of Medicine, 416  
 Cartilages, loose, in knee-joint, Mr. H. J. Alford on, 124; Mr. Square on, 245, 313  
 Casey, Dr. T., obituary notice of, 338  
 Cat, Dr. Brumwell on hydrophobia after bite of a, 434  
 Cataract, congenital, 510; Dr. H. Liebreich on extraction of, 633  
 Catheterism of the Eustachian canal, Dr. R. H. Taylor on, 548; Dr. S. Haynes on, 725  
 Cattell, Dr. T., administration of chloroform, 112  
 Cattle-plague in Chili, 14  
 Caution, galvanic, amputation of penis by, 384  
 Cayley, Dr., Middlesex and University College Hospitals, 485  
 Census of the British Isles, 43  
 Cerebellum, absence of, 180; tumour of, 242, 528, 787  
 Cerebrum, hyperæsthesia of, 371. See Brain.  
 Certificated, death, remarks on, 368, 674; letter on, 573  
 Chadwick, Mr. E., sanitary influences of town-pavement, 473; sanitary construction of schools, 482  
 Chambers, Dr. T. K., Harveian oration, 1, 310  
 — Mr. T., ovariectomy, 425  
 Chapman, Dr. J., nitrite of amyl in cholera, 426

Chapman's entire wheat-flour, 441  
 Chausseaud, Dr., Invasion and Propagation of Cholera, rev. 730  
 Cheadle, Dr. W. B., cirrhosis of the liver in early life, 545  
 Chemistry, Medical Council on teaching of, 68  
 Chicago, fire at, 759  
 Children, pauper, boarding of, 165; Dr. West's Lumleian Lectures on Disorders of the Nervous System in, rev. 11; Dr. Priestley on empyema in, 577; mortality among in Vienna, 589; ovariectomy in, *ib.*; injuries of, by nurses, 675  
 Chloral in delirium tremens, Dr. Broadbent on, 36; Dr. G. Elliott on, 63; in small-pox, Dr. Pollard on, *ib.*; in toothache, Dr. D. Page on, 263; large doses of, 437; in cholera, 531; action on fetus in utero, 516, 544, 573; in beer, 618; Mr. Browning on recovery after large dose of, 640; use of in New York Asylum, 643; toxic effect of, 670; in puerperal convulsions, Dr. Swayne on, 752  
 Chloroform, Mr. Clover on accidents from, 33, 278; Dr. Skinner on deaths from, 54; Dr. Petrie on, 85; Mr. J. D. Brown on death from, 93; Mr. Lister on accidents from, 117; deaths from, 134, 150, 388, 421, 619, 641; electro-puncture of the heart in apparent death from, 380; and ether as anaesthetics, 537; recovery after large dose of, 635; Mr. Bradley on death from, 641  
 Chlorosis, treatment of, 334  
 Chocolate and its adulterations, 564  
 Cholera, Sir Thomas Watson on, 141; Dr. Murray on, 175; Dr. G. Johnson on, 197; Dr. R. Martin on, 198; discussion on, 241; Dr. Brabazon on, 278; reports on treatment of, 324, 380, 433; Mr. G. Foote on sporadic case of, 352; Dr. Talfourd Jones on nitrite of amyl in, 378; letters on nitrite of amyl, 426, 451; chloral in, 501; Dr. Chausseaud on Invasion and Propagation of, rev. 730; notes of prevalence of, 16, 45, 74, 129, 156, 158, 185, 217, 221, 339, 372, 310, 333, 336, 365, 386, 423, 443, 473, 504, 532, 620, 733; precautions regarding, 155, 158, 182, 183, 186, 218, 220, 231, 239, 273, 383, 386, 588; order of Privy Council, 186; alarm of in London on, 419, 225; memorandum of medical officer of Privy Council, 221; course of epidemic in 1871, 237; epidemiology of in the Punjab, 469; the Registrar-General's prescription for, 271; accommodation for in London, 428; causes of in India, 589; the water-theory of, 626  
 — infantile, Troussau on treatment of, 332  
 Cholesteroline, spontaneous deposit of crystals of, 597  
 Chorea, Dr. J. K. Spender on arsenic in, 420  
 Christian, Dr. J. S., obituary notice of, 513; resolution of committee of Royal Humane Society on, 564  
 Christison, Sir R., bust of, 17; baronetcy conferred on, 564  
 Christmas in hospital, 736

# BRITISH MEDICAL JOURNAL:

BEING THE JOURNAL OF THE BRITISH MEDICAL ASSOCIATION.

EDITED BY ERNEST HART, ESQ.

LONDON: SATURDAY, JULY 1, 1871.

## THE HARVEIAN ORATION ON THE PROGRESS OF THERAPEUTICS.

DELIVERED AT

*The Royal College of Physicians of England,  
June 21st, 1871.*

By THOMAS KING CHAMBERS, M.D.,

Senior Consulting Physician and Lecturer on Medicine, St. Mary's Hospital.

I KNOW I shall be carrying out in spirit the intention of this oration's founder, when I ask you to join me to-day in reviewing the contemporary progress of therapeutics. While science is our privilege, art is our duty, and, quite as much as science, is capable of advance by that method of direct experiment, to advocate which Harvey bids me stand here. Now is a fitting time to take such a review diligently and often, for I am sure that this our art of healing is passing through a most trying crisis, which will decide the direction and place of its onward march in a most sovereign manner. Let our motto be *Vigilemus*, or we shall stumble and block the road.

This crisis I have elsewhere described by saying that medicine is now entering upon a biological phase. By this I mean that our practice is becoming yearly more and more influenced by that idea of disease which paints it as a mode of living, as an imperfect form of undeveloped vitality, as a loss of something present in health. Is this new? Is it true?

It is new; it is not implied in former theories of therapeutics. I must ask you to bear a little with the unpopular subject of medical history; for the advocates of various principles of healing have made their differences so strongly felt, that their important point of resemblance is somewhat overshadowed. And their point of resemblance is that in which they differ from the newer medicine of to-day.

The Athenian physicians were the first to recognise that health and sickness obeyed any universal law,\* and not the arbitrary wills of good or bad powers. They considered that the important point in disease was the excess of some constituent of the body—of phlegm in winter, of blood in spring, of yellow bile in summer, of black bile in autumn. This view still survives in the practice of *elimination*, and in the phrases of "reducing the fever", "clearing out the liver", "getting rid of the bile", and the like, so often in the mouths of patients.

Galen brought into pathology the notion of Force, as distinct from its object. To Plato's Life of Nutrition, Life of Animal Motion, Life of Volition, he added the idea of the foreign force of Disease. Diseases were foreign forces, foes to the native; and the duty of a physician lay in opposing them (*ἐναντίας*). Remedies were to be sought which in a healthy man would produce abnormal symptoms contrary to those of the disease. Nobody can deny that this cure by *contraries* holds its ground bravely, and will do so till we find sleeplessness not to be alleviated by narcotics, constipation not to yield to purgatives.

Its permanence has been in a great measure due to its openness to accept modifications and reforms. One of the most important of these is an extension of Hippocrates' suggestion that "diseases naturally contain their own cure" (*νόσων φύσες ἑαυτοῖς*) into Sydenham's designation of their phenomena as an effort of Nature (*Natura conamen*). This theory has been so salutary in promoting a milder and better treatment of acute ailments, that it too still influences deeply our pathology and therapeutics.

*Neutralisation*, by what may be called antidotes, is the application of chemistry to the cure by contraries. During a given disease there is found in the body a substance differing from what is found in health.

\* *Νόμος πάντα κρατεῖ.*—Hippocrates, *De Geniturâ*, I. 1.

United with certain drugs, it forms a third neutral and harmless substance. We will give those drugs. If the urine be over-acid, we will give alkalies; if it be alkaline, we will give acids. It seems as if contagious fevers were set in action by a ferment in the blood, so we will administer, in as large doses as we dare, chemicals which decompose ferments. Though sometimes leading us into blunders, this idea has certainly taught modes of treatment which relieve illness; so that it has advanced along with advancing chemistry from the time of our famous co-fellow, Dr. Thomas Willis,\* author of the *Pharmaceutice Rationalis*, up to the present time. And seeing that our generation of fellows has contributed a Dr. Prout, a Dr. Bence Jones, a Dr. Garrod, and many others, to the labourers in the cause, we cannot be surprised that valuable therapeutical results have arisen.

*Counterirritation*† is a principle of treatment which owes its prevalent application to the study of morbid anatomy. The idea is, by exciting artificial diseased action in parts under our control, to divert the diseased actions from a less accessible or more hazardous localisation. We see before us the fact that a spontaneously generated secondary disease is often rapidly followed by the cessation of a primary one, whether milder or more serious; and we infer with reason that the same result will be found if the secondary disease be the consequence of a drug. This therapeutic theory is obviously made more universally applicable by an exact determination of the parts affected; and, therefore, with the advance of morbid anatomy, has more influenced our practice. That this advance will continue, we have the guarantee of the devotion of our own Johnson, and Murchison, and Ogle, and Quain, and Sibson.

All rational cures seem to have resolved themselves into these five; namely, the Cures by Elimination, by Opposition of Contraries, by Assisting Nature, by Neutralisation, by Counterirritation. All except mere reactionary speculators have, till lately, followed the advances here implied. Examine each, and you will see that they are all agreed in one feeling as to the nature of disease; namely, that there is therein added to the animal frame something which needs to be reduced, or opposed, or assisted, or neutralised, or counterirritated. Now it seems to me that the tendency of the medicine of to-day is to take an essentially opposite view. Daily stronger and stronger an impression is being borne in upon the practitioner's mind, as expressed in his acts, that disease is something less, not something more, than life. Under the light of advancing physiology, morbid substances and processes appear examples of arrested development, each one the more as the more intimate is our acquaintance with it. The end and aim of happy treatment is, therefore, essentially an addition, an endeavour, to retain, to restore, to develop, into fuller life those identical morbid substances and processes which have hitherto been uniformly condemned to expulsion. When we are sick—

" 'Tis life of which our limbs are scant;  
'Tis life, more life, for which we pant;  
More life, and fuller, that we want."

To answer the question as to novelty in a more concrete form, take the yet unfinished collection of monographs on specified diseases which we are owing to the labours of our accomplished fellow, Dr. Reynolds—the first and second volumes of the *System of Medicine*. Compare each subject with its prototype in the *Cyclopædia of Practical Medicine*, published thirty-five years ago; and in no single essay will you find the treatment recently recommended to be more evacuant than that of old, or more antipathic, or more counterirritant. In a few instances it remains unaltered; but in the most you read of medicines advised "to support the strength of the patient" in diseases where the writer's teacher would have used the most active debilitants with the avowed purpose of weakening the disease.

The volumes are in the hands of all, and I will not sit in the seat of the reviewer by reciting examples. We have all seen the day when

\* Though Willis's reputation was mainly connected with Oxford, he was admitted an honorary fellow of our College in 1664.

† Dr. Parry calls it the Cure of Disease by "Conversion". But that word seems to imply change of nature rather than change of place, whereas in most of the examples of the influence of this principle the curative morbid process is either identical with or closely related to the ailment.

hospital-physicians gave five grains of calomel three times a day to cure acute rheumatism, mercurials and purgatives in enteric fevers, tartar emetic in full doses and venesection stroke upon stroke in pneumonia; when they narcotised with monstrous doses of opium the brain of a raving drunkard, exhausted with artificial sweats the moist skin of a gouty man, or turned his urine alkaline with soda and potash, and scalped with blisters the acute maniac and the hydrocephalic child. Were they not right according to the principles of Elimination, Contraria Contrariis, or Assisting Nature, or Neutralisation, or Counter-irritation? Go round the wards now, and you will find these extremes at any rate as nearly extinct as flint-locks or duelling. Indeed, the extinction has been in some instances too rapid; physicians have so hastened to cry *ἐπὶ οὐρανὸν ἰκάνον*, that they have forgotten to add *εὖρον ἀμείνον*; and, unready with a substitute, have displaced that which was certainly better than a vague expectancy.

If you look down the lists of new articles of *materia medica*, brought into common use of late, you will see that none are of a nature to augment destructive metamorphosis. Cod-liver oil, hypophosphite of lime, phosphates of iron, manganese, soda and potash, ox-gall, pepsine, pancreatine, are familiar instances of those whose intention is to form a basis of new cell-growth, thus being directly constructive.

The surgeon, too, when the skin is lost or wounded, builds up as good a restoration, or imitation, as he can, with collodion, or some other impermeable substance, to shield the inside tissues, instead of tearing them open to the bitter air, as in the horrible operation of dressing and cleaning. Again, with the expressed aim of limiting the resolution of their elements of diseased tissues, there are largely used antiscalds, such as carbolic acid, the subsulphites of lime, soda, and ammonia, while several sulpho-carbolates, chlorine, etc., are administered internally. On the other hand, permanganates, whose oxidising action is their distinguishing character, are given only when it is held wise to skip the dangers of the first stages of catalysis by hurrying them on. I do not know that I can cite alcohol as a new remedy, seeing it came into use so soon after the Deluge; but at all events our notions concerning it are new. Our fathers looked upon it as a fuel to life's lamp, augmenting heat, secretion, power, and vital action, and consumption in general. We find it to be in reality a damper to the flame. It has been used as a medicine, and as a good friend to poor humanity, throughout all these centuries; but now in a somewhat different class of cases, and with a better result, I trust. Though not a repairer of the waste, it is a conservator, and has thereby its own, though lesser, value. This change of use, without change of tool, has befallen many other old established remedies, such as iron, digitalis, quinia, arsenic, warmth, oxygen.

If you go beyond *materia medica* into pharmacy, you will notice that the energy exhibited by the deviser of new forms of old favourites has turned itself to constructive drugs in the proportion of nearly three to one of destructives. This shows the direction of prescribers' requirements.

There is an interesting class of substances of old called "alteratives", which may probably have light thrown upon them by the new movement of therapeutic thought. These agents are not in any wise eliminative, nor do they arrest elimination; in moderate doses they cause no symptom either opposed to, or like, the diseases they cure; their effects do not resemble the efforts of nature during sickness; and any toxic action they may exert is not enough to counteract anything, so that I do not see how their use is to be reconciled to any of the older therapeutic theories. Typical instances of this class are the iodides and bromides, of which the tonnage consumed is monthly increasing. Their sole effect in medicinal doses seems to be cure. Either nothing happens, or certain failing functions are restored to health without any morbid tissue being destroyed. The diseases to which they are applicable are so various that it appears at first impossible to find any common point at which the successful physic has touched them all. The connection is truly not obvious between syphilis, aneurism, epilepsy, neuralgia, gout, ague, hysteria, lead-poison, and acute hydrocephalus. Yet in certain cases of all such ailments this class of drugs is useful; and we need not discover wherein the kinship lies, or we can never attain to a rational use of the remedy. It has struck me—and indeed I usually act upon the thought—that they are related to one another in virtue of an *inferior vitality* of the white fibrous tissues with which bones and trust-nerves are sheathed. When a periosteum is tender from the syphilitic poison, iodide of potassium acts like a charm, while its influence on a chancre or sore throat is scarce perceptible. The same may be observed in rheumatism and in neuralgia. The bromide prevents with considerable certainty epileptic attacks which arise from injuries and pure to the pericranium; with less certainty, obscure cases whose cause you cannot trace, and very rarely congenital or hereditary instances of the disease. It heals the tissue, not the epilepsy. Deep-seated gout

racking the tendons is relieved by the iodide, but gouty urine and gouty indigestion are untouched. Lead-poisoning is also cured by the iodide, when it is given in painful or paralytic conditions of the limbs; but colic is not benefited. The same drug has rescued from death in a wonderful way cases of acute hydrocephalus where the membranes of the brain were affected, but has apparently no influence when the cerebral substance is inflamed. I should be disposed, therefore, to assign a neutral pathology to those cases of hysteria and of ague which I read have been relieved by these salts, for I suppose they will renew to health the sheaths of the nerves as well as the sheaths of the tendons and bones.

That which has above all things contributed to change of practice, is the gradual course of change in our ideas of inflammation. The last great teacher who has published a monograph on the subject—Dr. Alison—depicts it as "a local increase of a vital property" (*Library of Practical Medicine*, vol. i, p. 64), and urges the use of blood-letting to subdue it, on the express ground that the evacuation "weakens the heart's action" (*ibid.*, p. 98), to which weakening influence, indeed, he ascribes the power of all other antiphlogistics whatsoever. Monographs on inflammation have not been written of late years; but morbid anatomists, chemists, physiologists, and clinical teachers, of all nations and tongues, unite in speaking of it as "a perversion of nutrition". And to each one in his own department the perversion displays itself as in the direction of incompleteness. The anatomist sees it in the *premature expulsion* of new-born germinal matter which should have budded into tissues, but which now at best becomes a deformed scar, and more usually dies off as pus. The chemist points out the *defective oxygenation* which causes lithate of ammonia, uric acid, or oxalates, to appear in the urine, or an excess of fibrine in the blood. Inflammation is a cooling, not a kindling, of the furnace in respect of chemical power. The physiologist discovers the swelling, redness, and heat, of inflamed parts to be due to a *loss of elasticity in the smaller arteries*. He regrets his inability at present to explain the general rise of temperature; but as that sometimes occurs after death, he does not think it an evidence of increased life. The practitioner at the bedside, casting about among the means at his command for something to cut short inflammation with, finds that the nearest approach to such an end lies in replacing the loss of elasticity by pressure, by cold, by astringents, or by spurring up the contractile arteries to exertion with nerve drugs. Among the latter he reports well of quinine, and, finding that by its use the fever-heat is quickly lowered, he looks upon that high temperature as arising from diminished nervous control.

Morbid anatomists have also done much to shake the fixedness of our methods of healing, by finding evidence to show that what appear superficially different forms of morbid products are in reality different grades. That which distinguishes them is a higher or lower degree of vitality, a more or less of the characters of living flesh. As an instance, I may cite Gerber's classification of tubercle into (1) granular or unorganised, (2) cytoblastic, (3) cellular, (4) filamentous. Each form is a little higher than the other in the scale of resemblance to tissue.

This is no guide to prognosis, for the more highly organised growths may be the most destructive to neighbouring parts—indeed, in the case of cancer it would seem as if the danger were directly in ratio to the organisation—but it can hardly fail to influence treatment.

Another powerful agitator of therapeutic aims is the distinction made between disease and its cause, arising out of the attention paid to morbid germs. I think it wise at present to use the word germ in its widest sense, as meaning either a fragment of organic matter in a state of decomposition, or a fragment capable of resuming vital characters, or a separate individual. The investigation is being carried on by our co-fellows, Dr. Beale and Dr. Burdon Sanderson, with the aid of the highest powers of mind and microscope; and the facts elicited are too widely known to make needful more than allusion. But they all combine in leading us to draw a distinct line between the treatment of the disease and the treatment of the cause, between the management of the wound and of the bullet, which our forefathers were apt to pass over in their views of enthetic disorders. Whatever be the etiology of the germ, it is clear that the condition which results from it can be looked upon only as an arrest by obstruction in the life of the tissues where it is inserted.

The becoming conscious of these invisible angels of death, hourly drifting around us, reminds one of the opening of that mythical box of evils with which Horace has made us familiar; yet here, too, there is a hopeful germ at the bottom. We have to deal with (let us say) an unhealthy stagnant ulcer; we strip out a bit of clean skin, not so big as a mustard-seed, from the patient or a friend, and we plant it among the torpid granulations; it sticks, it unites, it lives, it feels, and becomes with its new home one flesh, not to be put asunder. John Hunter had taught us to expect this. But, better still, it becomes a centre of new

growth. Healthy skin begins to form round its edges. Praise be to the All-merciful ! not only disease, but health also, is contagious : better still, it is infectious ; it has stepped over the gulf of festering stagnation and is sowing growth along the neighbouring margin, throwing out peninsulas and promontories to join the parent piece of grafted skin. One who has experienced in his own person what uphill work cicatrization of a large surface is, must be pardoned some exultation at this surgical promise, and may be allowed an Utopian dream of restoration which would throw present success far into the shade. Even the practitioner upon others' ailments cannot but feel enthusiasm at the revelation of this important law of Nature. Does it not promise to explain the hitherto inexplicable benefit derived from firing, blisters, mustard, croton oil, caustic potash, and other means of cure by external sores ? It is when the artificial sore is getting well that the benefit arises : as the new healthy tissue shapes itself outside, it infects the diseased parts with health.

It is possible, also, that by applying the same principle to blood-letting we might learn the true use of that now unpopular treatment. We have left it off because it failed to do what we had been led to expect of it : but may it not have another use in a differently selected class of cases ? May it not set in action the healthy formation of new blood, replacing over and above the previous loss ? However, I must not trespass on your time with untried speculations.

I am not telling the tale of a buried event, but aiding to record what is passing under your eyes ; an instance of theory grounded on experiment paving the way for practice. Not experience is teaching us these things, but designed scientific experiment. It is this path of progress which our immortal Harvey bids me to-day exhort you to follow. \* Arduous, indeed, it is, and tangled, yet leading always on, and much freer from pitfalls than that direct empirical method of trying remedies which Hippocrates has so emphatically pronounced "slippery". Science may guide us slowly, but she never guides us backwards.

In no direction does there seem a more favourable opening for experiment, at the present day, than in that to which the name of Harvey is for ever attached. The mysteries of the circulation are now open to be unravelled by new instruments of precision of yearly growing ingenuity. The improved microscope, the ophthalmoscope, the sphygmograph, and the dynamometer, may help lesser wits to make discoveries of which Harvey would have been proud ; while the use of chloroform removes the serious objection urged by humanity against experiments on animals. We are not asleep : our Sanderson is justifying his scientific surname by devoting to the increase of physiological knowledge months and years during which, with less labour, he might have heaped up wealth. I especially introduce his name here because the sphygmograph, which he has tried to make popular among us, † is the embodied acting up to a principle of great importance in Harvey's eyes—the ocular demonstration of scientific truth. I need go no farther than this room for an instance. Those brown boards over our heads, ‡ in spite of time and neglect, exhibit the complete arterial systems of two bodies, dissected out and dried *in situ*. It is a work of months, if not of years ; and I doubt not but that some will denounce as sinful waste the employment of Harvey's fingers in such mechanical handicraft. He thought differently, and held no labour thrown away if spent in producing a lively mental impression, such as we gain from those preparations. Herein lies the great merit of the sphygmograph. The obscure feelings of the finger-tips are brought under the cognisance of the sense that most directly affects the mind—*oculis subjecta fidelibus*—so as not only to be shown, but "delivered in number and weight", as the son of Sirach advises all material things to be estimated. Do not think of the pulse portrait-painter, even as at present perfected, as a mere physiological toy. Had it done no other good deed, eternal gratitude would be its due for putting down the tyrannical imposture of the *tactus eruditus*—for no one has vaunted such erudition from the time when it could be tested in black and white. But I think a sphygmograph can do more than that ; it can tell us what really existing movements to feel for in the pulse. The tool may sharpen the wits that use it, and teach its pupils in the end to dispense with its services.

Since Harvey, the physiology of the sanguineous circulation has been pushed on by many distinguished men, but I do not know of any step more important than that made during the last two years by the French *savants* Messrs. Legros and Onimus. By an elaborate series of experiments they have deciphered the riddle which has puzzled Harvey and Hunter, Magendie and Claude Bernard—how the microscopic

arteries assist the current of the blood through the capillaries. Indeed, it puzzled the last-named physiologist so much, that he definitely confined the agency of the arterioles to resisting the force of the heart. To Messrs. Legros and Onimus this did not seem to accord with the economy of nature in working the way of fluids through other organic tubes. It was a wasteful expenditure of force. Spurred on by this thought, they sought, and they found, in the arterioles a regular peristaltic wave, an intermittent progressive muscular action, such as that which carries the morsels down the oesophagus, rolls the mass round and round in the stomach, and passes it along the ilia. With a microscope they were able to follow this newly seen wave in the frog's web, then to detect it in the transparent part of the rabbit's ear, then to see it with the ophthalmoscope in the human retina. It seems to me that a very wide field, indeed, for experiment is opened by these observations. A knowledge of the action of remedies on this peristaltic circulation generally would form a new standing-ground for rational therapeutics ; and the discoveries by Waller and Bernard of special systems of vaso-motor nerves, governing special parts, might be made practically useful.

It seems to me, also, that our various mechanical and other means of observation have arrived at a degree of perfection sufficient to allow of prosecuting with advantage researches into the genesis of disease by direct experiment.

The most certain way of knowing how a thing is generated is to generate it yourself. The lower animals must of course afford the material on which the bulk of these experiments can be made ; and it is, therefore, of the utmost importance to know how their bodies and liabilities to morbid phenomena differ from those possessed by us, so that the necessary allowances may be calculated.

Most opportune to the gaining such knowledge is the prospect before the country of the permanent establishment of an institution for the study of the diseases of animals. I am in hopes that the certainty of advancing science, open to the staff of this institution, will make its offices an object of ambition to those among us whose age renders ambition still graceful. They will be able to feel, not only that they are promoting the selfish interests of mankind, but that they are repaying in a substantial manner the services of our devoted immemorial slaves. For it must be understood that the final view of the foundation is distinctly charitable, and that the cure of animal disease is the end to be attained by its study.

The bulk of these experiments must be doubtless carried out on inferior creatures, and, therefore, must wait upon a parallel prosecution of comparative pathology. But there are examples of the study of disease by entheses to which our own noble bodies have lent themselves—lent for an ulterior advantage, no doubt, and therefore I used a word implying no notion of sacrifice. The cases of vaccinia and syphilis may be especially cited as instances of a more than usual knowledge of a disease's etiology, being due to a study of it as artificially implanted.

All, however, cannot hope so usefully "to study and search out the secrets of nature." Many wise people, praiseworthy for self-knowledge, are aware that the quality of their intellectual powers, bodily weakness, education, or social duties, disable them for playing the part. Harvey bids me say a word to them too, when he enjoins the orator to hold up for imitation those who have ministered of their substance to our College.

The "Comemoration of all the Benefactors of ye sd College by name," has its place taken by those boards in the theatre on which even the smallest contributions are from time to time recorded. We have not forgotten even the window-cushions and table given by the unlucky Lady Arabella Stuart, though they perished in the fire of London, I suppose. Let us not think scorn of a care for the bodily comforts of those who are executing a trust for our benefit. Hospitality, of which these gifts are an humble form, is a high Christian virtue, and is all the higher for her humbleness. I feel very glad that of late years our College has itself resumed the exercise of this virtue by reviving, albeit in the somewhat sad shape of *conversazione*, that domestic feast which Harvey gave us money to pay for.\* It had been omitted for many years ; not, I fear, from self-denial on the part of the Fellows, but because a proud and luxurious age despised the frugal festivities of its forefathers. To those simple souls, as to Sir Toby Belch, "cakes and ale" was a synonym for a merry-making. On less than that, indeed, the censors are expected to make merry once a month ; † and, doubtless, the annual joviality was equally wholesome and economical as that monthly repast. You, however, have degraded into a ballot-box the

\* The commemoration of benefactors is to be accompanied "with an Exhortation to the Fellows and Members of the said College, to search and study out the secrets of nature by way of experiments."—Harvey's *Deed of Gift*, MS.

† In the Lent Lectures of 1869 at the College, and in his *Handbook of the Sphygmograph*.

‡ The Tabule Harveianæ in the gallery.

\* "And that once every year there shall be a general feast kept within the walls of ye sd college for all ye fellows yt shall please to come."—Harvey's *Deed of Gift*, MS.

† In accordance with Harvey's wish, a packet of cakes and coffee is provided for each Censor at their meeting.

punch-bowl given you by Dr. Freind and his co-censors (in 1719), and scorn to dine abroad unless tempted by French cookery and the costliest vintages. We have at any rate the grace to feel that gormandising would be misplaced within our walls; and, until prevalent habits become more moderate, I do not see that we could carry out Harvey's wishes in any mode better than by this *conversazione*. Let us, however, look upon it as a provisional feast.

Some of our benefactors are distinguished as the founders of sundry lectureships called after their names, with which you are familiar. Applied, as intended, to the ocular demonstration of physiological discoveries, these are still made useful.

Notwithstanding, I cannot conscientiously exhort you to a literal following of Croone, or Gulston, or Lumley. The date of a small volume in your library, published by William Caxton, at the bottom of the next street, in 1471, reminds you that four centuries ago there had begun a revolution which renders the foundation of new lectureships an anachronism. The printing-press has crushed the pulpit. It is wise to accept the fact, and to devote to the spread of knowledge by the newer mode, those funds in the disposal of which we may wish to rival the open-handed among our ancestors. There is no way by which a man shall more surely hand down his surname to futurity than by linking it with the publication of the researches of others in a more liberal form than their incomes allow. Remember that you have at your disposal not your own purses only, but that those of your patients will often open at your bidding. I read in the annals that the table and cushions I have alluded to were given "suasu Doctoris Moundefordi," and I commend the example to your imitation. Dr. Moundeford had been a kind friend to Lady Arabella during her struggle against the mean tyranny of James the First; and he apparently preferred that the graceful acknowledgment of his kindness should be paid to his college rather than to himself.

Those who like modern instances best, may find one in the noble contest last year between our co-fellow, Dr. Quain and Mr. Cunliffe, the banker, as to which should give £2,000 to secure the building of the Brown Institution for studying diseases of animals.

I have represented designed experiment as the sharpest spur to the progress of rational medicine. But doubtless the guiding vein is observing experience. And it is by experience alone that we can be led to the answer of the question which I asked at the beginning, namely, whether the view which influences modern therapeutics be true as well as new. Some hint as to the future answer may be gained from the more favourable prognosis we are now enabled to give in several diseases whose course is marked and import grave, such as rheumatic fever, pericarditis, pneumonia, typhus. But the final solution must be found after many years in a continuance of the physical improvement noticeable throughout our native population, in increased length of life and diminished liability to fatal sickness, as witnessed first by increase in the profits divided at insurance offices, and latterly by the lessened mortality of the whole population.

To the court of experience we are, one and all of us, called as jurors. There are millions of experiments performed daily by observers who can regulate their conditions. But how are we prepared for turning the experiments into account? What training does the medical student go through which shall enable him to exercise his franchise? I cannot but say that those of us who are teachers in schools have greatly failed of our duties in this respect. I have never yet, as examiner, come across a candidate for diploma, instructed in the art of systematically observing and recording the action of medicines. What an awful waste of raw material is here! Surely the chairs of *materia medica* would be better employed in training a class how to observe, than in discussing varieties of cinchona bark or the shape of senna leaves—a kind of knowledge which no one ever really gets from lectures, but, if he require it, either from a book or a warehouse.

To the court of experience we are one and all of us called as jurors, but more especially those who have the privilege of hospital practice. The duty of aiding in the decision of these questions, by communicating the knowledge gained from our patients, is one that cannot be evaded, and is incumbent upon us to the end of our lives. It can no more be thrown off than can the obligations of a crown, or of inherited wealth. I have sometimes been asked how it is that medical men seldom retire, and usually die in harness; and I say that their harness is their uniform, their decoration, their chiefest reward, and that they lay it aside only at the bidding of their commander-in-chief. When I was in Italy some years ago, on a holiday tour, enforced by a surgical operation, I hesitated whether I should not lengthen my holiday to the end of my life, and leave the race to the swift, the battle to the strong. "Were it not better done, as others use, to sport with Amaryllis in the shade, or with the tangles of Nessus's hair?" In visiting Pompeii, I stopped more than once at a sentry-box by the sea-gate, where there

were found the skeleton and arms of a Roman legionary set on guard eighteen hundred years ago. That nameless sentry, I thought, ignorant, sensual heathen, whose flesh lies mouldering among the *débris* of brothels of unmentionable atrocity and filthy wineshops, will yet to the resurrection-call answer "Adsum, Domine!" from a vantage-ground of dignity second to none in the universe—at his post, waiting for orders to leave. And so I turned and came home.

## THE ANTISEPTIC TREATMENT OF WOUNDS.

By EDWD. DRUMMOND, M.D. Edin., M.R.C.S. Lond., Oldham.

AMONG four cases in the practice of the Liverpool Royal Infirmary (illustrative of the treatment of wounds on the principles laid down by Mr. Lister), published in the JOURNAL of May 6th, is one of strangulated hernia, in which the wound healed in three days. Having recently treated an almost identical case, with the result of perfect union by first intention, I think it not unworthy of mention.

K. S., aged 30, a member of a family hereditarily disposed to hernia, has been the subject of the oblique inguinal form for six years. I was summoned at six o'clock on the morning of May 3rd, 1871, the hernia having become suddenly strangulated. Having failed with the taxis, I performed herniotomy, the patient having been chloroformed by my friend Mr. Bromley. I opened the sac, and returned a knuckle of intestine and a large portion of omentum. At 6 P.M., I closed the wound with three silver wire sutures and strips of emplastrum saponis, placed a pledget of wet lint over the wound, and applied the usual bandage. Next day, she had passed a good night, and was doing well. The following night, the patient was attacked with abdominal tenderness and purging. I saw her at 6 A.M. on the 5th, and ordered two grains of opium immediately, followed by grain-doses every hour. At 9 A.M., the pain was almost gone, and the purging was arrested. At 7 P.M. (forty-nine hours after operation), I removed the dressings, and found perfect union by first intention. The patient got up on the fifth day.

This case shows that at least equally good results may be obtained without as with antiseptic precautions. I found the carbolic acid dressing in use in the York County Hospital in the summer of 1865, but was unable to see that it possessed any special virtue. Ever since the publication of Mr. Lister's views, I have carefully carried out the more elaborate treatment which he suggests in almost every case under my care, including amputations, resections, excisions of tumours, etc.; and the balance of evidence in my mind has been generally in its favour. For example, I removed recently a large fatty tumour by two semi-elliptical incisions eleven and a half inches in length. The wound, closed by fourteen silver wire sutures, and treated antiseptically, healed throughout in four days, without a drop of serum or pus. I am unwilling, therefore, to place myself among the number of those who disbelieve totally in the antiseptic treatment; but I cannot help thinking that the time has arrived when we may look for some authoritative settlement of the question. In medicine, and in a lesser degree in surgery, the tendency has ever been to exaggerate the benefits of new methods. We are all prone *jurare in verba magistri*—ever, let us hope, laudably anxious to be the pioneers of a new era in our art. Can we not, by treating parallel cases with and without carbolic acid dressing, definitely decide whether, on the one hand, the antiseptic method is all its enthusiastic advocates believe it to be, or, on the other, save ourselves from the opprobrium of unduly vaunting a means of treatment which will not stand the test of experience?

THE ENDOSCOPE IN MILITARY SURGERY.—The *Wiener Medizinische Wochenschrift* for June 24th contains a paper by Dr. Christian Fenger, of Copenhagen, in which he suggests the application of the endoscope in the examination of bullet-wounds. From experiments on horses, he last year came to the conclusion that, by means of this instrument, the surgeon may be enabled to see pieces of clothing that have been driven in, or bullets impacted in the cancellous structure of bones; and, having seen them, to remove them easily by means of proper forceps, etc., introduced through the tube of the endoscope. While attending one of the ambulances in France during the late war, he had no opportunity of examining wounds in the early stages; but, in several instances in which he made an examination some weeks after the receipt of the injuries, he was enabled, by introducing an endoscope, to see the interior of the wound distinctly. The introduction of the instrument caused no pain nor hemorrhage, nor any subsequent irritation. To what extent the suggestion as to the removal of balls and foreign bodies can be carried out in actual practice on the human subject must, Dr. Fenger says, be decided by the future.

## THE HASTINGS PRIZE ESSAY,

1870.

ON DIGITALIS: ITS MODE OF ACTION  
AND ITS USE.

By J. MILNER FOTHERGILL, M.D.,

Senior Resident Medical Officer to the Public Dispensary, Leeds.

IN bringing forward a subject so debated as digitalis and its action, the only apology the writer can offer is, that for years he has studied its effects clinically, having had patients continuously under its use for no less a period than three years and a half uninterruptedly. He has tried to bring to the inquiry a mind free from prejudice on either side, and impressed with the wish to elicit the truth. Physiological experiment has been largely resorted to and carefully observed; and, finally, the writer has carefully striven to give his results honestly, and to record what he thinks digitalis can do, and what it cannot, and, further, why he thinks so. It may be desirable to commence with an account of the different experiments performed, and the results obtained; and all through the inquiry he will regard digitalis as a member of a group of agents, rather than as possessing any qualities which are unique or peculiar to itself.

*On Plants.*—Marcet and Brunton have separately tried the effects of digitalis on the haricot bean by watering the plant with an infusion, and found it to kill it by withering it up. The writer injected a strong infusion into the hollow stems of the ordinary bean without effect for days; in time, however, those so treated withered and died, contrasting with those not interfered with. Precisely the same results ensued from similar injections into the orange lily. A lettuce was frequently watered, in a dry season too, with a strong solution, without any perceptible injury to it either soon or late. Another was then dug up by the roots, and placed in a large basin containing a strong infusion of foxglove, and for a day or two grew amazingly; on the fourth day, it commenced to wither, and died in a day or two. The first effect of the drug was to improve the appearance of the plants to which it was administered; an impression to the same effect remains in the minds of friends who witnessed the experiments. Strong infusions were injected into the stem of the rasp, and into holes bored into a plum tree without apparent effect.

*On Invertebrata.*—Snails, when touched with the tincture or strong infusion, took a contractile spasm, threw off a coating of mucus, and passed on apparently unaffected. Earth-worms, when placed in an infusion for a short time, did not appear incommoded. Wasps were not affected by it when applied to them.

*On Fishes.*—Minnows, when placed in an infusion of digitalis, a very weak one, for some minutes were not affected; then commenced a rapid movement of the gills, which lasted till death; they were also drawn to one side in dying. After death, the ventricle was found firmly contracted and glistening like a speck of gristle; and, on being examined under the microscope, no cavity was visible. The auricle was distended and vainly tried to drive any blood into the tightly contracted ventricle, the blood merely regurgitating into the venous sinus behind, and then flowing back again, from the venous distension relieving itself on the auricular diastole. On pricking the venous sinus so as to permit the escape of the contaminated blood, the auricle soon also became firmly contracted, and no cavity was perceptible under the microscope. The quickened action of the gills was probably due to the accumulation of carbonic acid in the blood, giving rise to an increased necessity for breathing, while the firmly contracted ventricle prevented the flow of blood to the branchiæ, and cut it off from oxygenation.

*On Birds.*—About half a drachm of strong infusion of digitalis was passed down the throats of two sparrows, some being spilled during the process. The animals soon became unable to move much, and gasped for breath most vigorously. The hen died first, and the cock died hard in about half an hour. On opening them immediately on death, the left ventricle in each was found firmly contracted; the lungs so congested as almost to be hepatized; the right ventricle full of blood. It was evident that the condition of the lungs and right ventricle was due to inability to drive the blood into the contracted left ventricle. The gorged condition of the lungs accounted for the gasping respiration observed. Side by side with them, ten drops of Fleming's tincture of aconite were administered to a third sparrow, who became convulsed,

and died in about one minute and a half. In it, the lungs were pale, and the heart completely paralysed and distended, looking like a small Barcelona nut. The contrast between the two conditions was marked.

*On Mammals.*—Experiments have been made on the higher animals by Handfield Jones and Fuller, with similar effects as regards the state of the heart after death.

*On Frogs.*—These have purposely been put last, on account of the large number of experiments to which they have been subjected by various writers. Frogs have been made much use of by experimenters, on account of their great susceptibility to medicines, and the ease with which experiments could be carried on. Dybrowsky and Pelikan abroad, and Hilton Fagge and Stevenson in England, experimented largely on them, with uniform results as regards the state of contraction of the heart observed. The manner in which the writer experimented was this. The frog having been firmly secured to a piece of lath by a bandage, leaving the chest exposed, the chest was then opened with a pair of scissors up the middle; the heart usually appeared through the incision, and was readily cleared of its pericardium. It thus beat with much regularity, apparently not much affected by temperature or air. It may not be out of place here to state that, when thus exposed, the cardiac contraction was clearly seen to be a swiftly passing peristaltic action, commencing in the auricle (as first described by Schiff and corroborated by Valentin), and passing rapidly on to the ventricle. The complete distension of the auricle stimulated it to contract in the direction towards the ventricle; this action, driving still more blood into the already distended ventricle, produced such distension of it as stimulated it to contraction; after the systole came a period of muscular rest, during which the blood poured from the distended veins into the lax chambers, until the distension of the auricle led to a general systole. Digitalis was then administered by the mouth, or hypodermically, and its effects were quickly apparent. First, the contractions became somewhat quicker, and the contraction more complete; and here it may be stated that, whatever may be the normal state of the human heart in systole, certainly the frog's is not thoroughly emptied, and is still dark coloured from the colour of the contained blood, showing through the transparent walls, which are quite white when thoroughly contracted. Soon the peristaltic action became more marked, the systole being longer and more perfect. Then the distension became less complete, especially at the apex, which remained white and firmly contracted. Here and there were little sections, apparently belonging each to a separate cardiac ganglion, which did not seem affected, and in the general contraction pouched out, contrasting in colour, too, with the other contracted and whiter portions: these are the crimson pouches of Dybrowsky and Pelikan. The action of the ventricle became almost vermicular in its slowness, and the diastole was most imperfect, till the ventricle came ultimately to a standstill in firm contraction, the heart being much diminished in size—and in size, shape, and colour, much resembled an unripe apple-pip. The frogs did not seem much affected otherwise, the poison seeming to be confined, as regarded its action, purely to the heart. If released, they hopped about unconcernedly, nor did the removal of the contracted heart by scissors cause them any apparent inconvenience. They merely seemed to die ultimately from the arrested respiratory changes: a slow mode of death in cold-blooded animals. In accordance with the observations of the above mentioned experiments, my results were uniform as regards the contracted condition of the ventricle. To other frogs were administered belladonna, caffeine, strychnine, and aconite. The first produced rather marked contraction; caffeine somewhat less so. Strychnine produced no perceptible effect, contrary to anticipation. Aconite produced paralysis and arrest of the heart in diastole. A still more interesting series of experiments was performed. To some frogs, digitalis and aconite were administered, side by side, and the opposite actions contrasted. The experiment was then varied; and, after the action of each drug was well established, the other was administered—i.e., after the effects of digitalis were well established, aconite was administered; and to others, after the action of aconite was well brought out, digitalis was given. Over the action of digitalis, aconite certainly had an influence, but it could scarcely be called a marked one, and did not ultimately arrest the contraction produced, even when pushed. On the contrary, the administration of digitalis was followed by the most marked results, when aconite had been given, and the ventricle had become gradually more and more distended, and its contractions more and more imperfect, each contraction merely expelling a small quantity of blood off the top of the distended ventricle, the contractions becoming slower and slower, and less and less perfect, until a condition of advanced dilatation had been artificially produced; and even when the heart seemed to have given up all action, and remained in diastole, distended with blood and inert. When all action had apparently ceased, the first

effect was to produce an imperfect contraction at long intervals; then the intervals became shorter and the contractions more complete, some irregularly both as to time and amount of contraction being observed. Slowly and gradually, however, the distended ventricle recovered itself under the action of digitalis, the contractions being more rhythmical and perfect, and the distension less and less pronounced, until a return to normal contraction and distension was brought about. If the administration of digitalis were then continued, the same appearances were brought out as when no aconite had been previously given. This interesting experiment was frequently performed before other medical observers, and can be readily repeated. In all the experiments the ventricle was the most affected; in the frog, where there is only one ventricle, the auricle could only remain distended behind it, incapable of getting rid of its contents into the firmly contracted ventricle in front, and of course it could not contract unless its contents could be disposed of: if the venous sinuses behind were pricked, as in the case of the minnows, the auricles soon became contracted. As regards the effects upon the rhythm, the general results may be stated broadly thus: at first there were occasional slow beats, interposed without any exact order; and then, as the effect became more marked, the slow beats preponderated, until the contractions were only occasional before complete cessation in systole. During an experiment on a dog by Brunton and Gamgee, a temporary murmur was observed, which they concluded was due, and apparently with good reason, to an irregular action of the muscular papillares, producing imperfect closure of the mitral valve.

In these experiments on the frog, sometimes the tincture of digitalis was used, and at other times the infusion. In some instances, a solution of digitalin was used, but its effect in producing increased contraction was certainly not so marked as when a preparation was used which contained the other principles. It is not intended that this statement should convey the impression that there exists any good reason for supposing that digitalin is not the active principle in digitalis; but such is the writer's experience.

Hilton Fagge and Stevenson found that, sometimes, the ventricle makes only one pulsation for two of the auricle, the number of its contractions being therefore lessened one half (*Transactions of the Royal Society*, May 1865, Conclusion 3). Reid seems to think that sometimes more than one auricular systole is necessary to produce such ventricular distension as would excite contraction. This seems in accordance with reason and fact.

**Composition.**—The leaves of digitalis have been subjected to repeated chemical examination, chiefly by foreign investigators. It has been found that there are various substances, which can be separated from one another, contained in them. The principal of these is digitaline. Indeed, by some it is considered the active principle; but of this I am not convinced; certainly it did not act on frogs so powerfully as the tincture of the leaves did. It is, however, frequently used. Digitaline is light yellow, inodorous, and crystallises with difficulty, and presents the appearance of very imperfect crystals, if crystals at all, under a pretty high magnifying power ( $\times 250$ ). It does not contain nitrogen, nor does it neutralise acids. It is a principle, not an alkaloid. It is soluble in sulphuric acid, and also in hydrochloric acid. The solution in hydrochloric acid passes from yellow to a fine green. Homolle considered this reaction sufficiently delicate for medico-legal purposes. It is scarcely necessary to state that it is not generally accepted as being so. There are also digitalic acid, digitalin, digitalose, digitalide, of whose qualities we know nothing. There are also tannic acid, sugar, and a substance named pectin, chlorophyll, and woody fibre.

**Chemical Characteristics.**—A dark precipitate (tanno-gallate of iron—Pereira) is formed on the addition of sesquichloride of iron to the decoction, or to a mixture of the tincture and water. A solution of gelatine causes a scanty precipitate (tannate of gelatine). Tincture of nut-gall merely causes a slight turbidity. There is no reason to suppose that any of the active principles are affected by these combinations; or that the drug is rendered inert by anything that we know. For a fuller account of its principles, the reader, if curious, can consult Pereira, or the *Therapeutics of London*.

**On the Blood.**—Magendie and Thackrah thought the addition of a decoction of digitalis interfered with the coagulation of the blood. Davy states that the addition of a large quantity of watery extract to blood gave it the consistency of paste. So far as I know, no English observers have recently noticed anything peculiar in the blood of animals experimented upon. And in the large number of animals experimented on by me, there never was any appearance about the blood which made it different from any other blood. No scientific observations of any kind have yet been instituted as to the action of digitalis or any of its constituents on the blood, such as have been performed by Harley, Bernard, Fraser, and Crum Brown and Broadbent, on some other therapeutic agents, by which their action has been

much elucidated. At this point, it may be desirable, in order to elucidate the subject thoroughly, to take a bird's-eye view of the manner in which the heart's action is maintained: the manner of its disorder, the mode of production of its affections of its vascular walls, and the mode of action of the drug.

**The Heart's Mode of Action.**—The heart, as has been shown by Pettigrew, consists of several folds of organic fibre-tubing folded on each other; it is thus capable of distension and rhythmical contraction. For this purpose, a singular system of innervation, motor and co-ordinating, is provided. The real motor power of the heart is under the control of minute ganglia, each with a morsel of muscular fibre under its direction, which are alone capable of carrying on the action of the heart, but only in a tumultuous manner, as seen after section of the vagi. As with all other accumulations of organic fibre, the distension by contents leads at length to contraction in a more or less rhythmical manner. The vagus exercises over this a co-ordinating (von Bezold), or even an inhibitory action; i.e., the application of a stimulus, as electricity, for instance, to the vagus, retards the cardiac contractions, and, if the stimulus be powerful enough, arrests the heart's action in diastole. The vagus then normally acts against the first impressions of distension, and only permits contraction when the distension is sufficient to produce uniform contraction, which then goes on in a truly peristaltic manner, but so swiftly as to be easily mistaken for a simultaneous general contraction. Thus, to some extent, distension and the action of the vagus balance each other; any disturbance of that balance, then, would produce irregularity, no matter in what direction the disturbance might lie. There lies, too, in organic muscular fibre, an inherent power of growth to meet demand; thus, if increased strain be thrown upon the heart, increased growth of muscular tissue, in health, takes place, and again the balance is restored between the blood to be driven and the power to drive it. When, however, from any cause, there is a deficiency in the compensatory nutrition, a species of balance is again struck, but of a lower form, by distension of the fibres, or, in other words, dilatation. In fact, there is planted in this comparatively simple cardiac innervation, a more complex one of contraction and reduction of the ventricular cavity on the one hand, and a species of normal distension on the other. These actions are regulated by nerves which have been dissected out in the rabbit, and experimented on by MM. Cyon, Claude Bernard, and others. The one which calls into action an increased action against obstruction is called the *accelerator nerve*; and the other, which admits a normal distension of the walls, is called the *depressor nerve* of the heart. Claude Bernard has even gone so far as to state it as his opinion that, through the action of the latter, a species of distension may so take place in accommodation to existing circumstances as to convert the cardiac chambers into temporary blood-reservoirs. This their construction as organic fibre would permit; for organic fibre permits great distension without abolition of function. Thus, while carrying on the circulation by expelling a quantity only of the contained blood off the top of the ventricle, and permitting a large portion to remain on each systole, this accommodation is allowed without bad results. This is undoubtedly no rare occurrence, if clinical observation were exact enough. Thus, between the ordinary balancing powers of the obstacle of the blood to be driven, and the muscular power to drive it, of the stimulating effects of distension in producing contraction, and the controlling action of the vagus, the heart's action ordinarily rocks; but, in addition to that, there is a more complex system of accommodating distension on the one hand, and an accelerating contracting action against an obstacle on the other: which exercise a regulating power according to special circumstances. Ordinarily, however, the action lies between the first set of nerves, with the driving power, and the work to be done. With their disturbances of balance, we are now more especially engaged.

**Distension.**—The first action of disturbance of this balance is engorgement or distension. When much blood has been located in the ventricles, and they are not capable of completely emptying themselves, a portion remains at each systole. At each diastole, however, an equal quantity of blood is again thrown into the ventricle, and thus at the next systole a larger quantity remains unexpelled; and this process goes on until death, or until some compensatory relief is attained. This relief is usually attained by congestion of the veins, and the system suffering. This distension or, if chronic, dilatation is produced in many ways, thus:—1. Pouring in of the blood under increased pressure, as in the enlargement of the left ventricle, which follows in time on mitral regurgitation, and increased action of the right ventricle and thickened pulmonary vessels; 2. Muscular failure from defective nutrition, as in *revers*, in coronary atheroma, or pericardial adhesion; 3. Obstruction to the flow of blood forwards, as in deposit of fibrine on the semilunar valves, diseased vessels, etc.; 4. Disorder of innervation, as a disturbance of the balance between the sympathetic ganglia and the action of

the vagus; 5. Excessive exertion and consequent cardiac exhaustion; 6. Valvular insufficiency. This condition may pass on to permanent dilatation.

*Mode of Repair.*—The ordinary modes of repair of this condition are two: first, relief of the condition on which it depends, where practicable; and, second, hypertrophy, when it is due to increased difficulty in the flow forwards, or to valvular insufficiency, by that power of self-increase which is allowed to all muscular fibre, but with which organic muscular fibre is endowed *par excellence*. Restoration of the balance may take place in three modes, of higher and lower grades: 1. The highest, restoration of the cavity to normal size; 2. Hypertrophy, by increase in number of fibres (Forster) and thickening of existing fibres (Bamberger and Rokitsky)—a compromise; 3. Dilatation, a permanent distension—the lowest restoration of balance, and entailing diminished vital capacity to a point proportioned to the heart's lowered power.

The signs of this disturbance of balance, or partial asthenia, are three—palpitation, irregularity, intermittency.

1. *Palpitation.*—The first evidence of failure of power is palpitation. It is undistinguishable from increased action, except in deficiency of results. When there is excited action, as in exertion or excitement, it is perceptible in the bounding pulse, or, with the sphygmograph, in the increased apex-beat. Palpitation is not so accompanied; and though to auscultation and percussion the heart-stroke may appear identical, it is in the results the real difference lies. Palpitation is a laborious heart-stroke, but not a stronger one. It is the evidence of effort, not of capacity. It is barren in result—a laborious stroke in place of a normal one, but not of more effect, not always of so much. It is intimately associated and commonly mixed up with the next form—irregularity. Palpitation may be engrafted on symptoms of chronic insufficiency as a temporary condition; as, for instance, in the palpitation of Bright's disease, or of slight exertion in a dilated heart from valvular insufficiency. Palpitation is a violent effort of the heart-walls to overcome the action of the vagus, *plus* the obstructed flow.

2. *Irregularity.*—Irregularity of the bulk of blood transmitted into the arteries is one thing, and is due to auriculo-ventricular incompetence. Irregularity in time is another. The latter is under consideration here. Irregularity of rhythm is not due to disordered innervation, but to obvious debility. It is an arrest in the commencement of the peristaltic contraction or heart-stroke. The controlling action of the vagus arrests the contraction until such time as the layers of fibres acting early on the systole ought normally to have acted; and then a sharp, almost simultaneous contraction takes place, with an increased thud against the chest-walls. This action is homologous with the increased action of the muscular fibres, under the control of the cardiac ganglia, when the systole has been retarded by stimulation of the vagus. Sometimes it appears as if the action of these layers, acting early in the systole, had been lost; and there is a perceptible change of action in the heart, as if the contraction were commencing from a new layer or set of fibres. Richardson has compared this to a change in order of a number of strikers on an anvil. It always reminds the writer of a horse changing its feet when cantering. This is a more serious evidence of over-taxation of the heart, and is often found mixed up with palpitation. It is often the result of over-exertion, and affords strong suspicion of ventricular distension. Chronic irregularity may have engrafted upon it a passing palpitation from an intercurrent additional disturbance of balance. Nervous irregularity and palpitation will be considered in a future section.

3. *Intermittency.*—This is sometimes purely nervous, and is inexplicable. When persistent, it is usually associated with an impaired first sound, defective apex-beat, and other signs of degeneration. The occurrence of palpitation during this condition sometimes clouds the diagnosis, and makes it very difficult. Intermittency of ventricular contraction is not identical with intermittency of radial pulse, though related to it. In some cases of intermittency of the radial pulse, if the stethoscope be applied while the pulse is held, a ventricular contraction will be distinguished when there is no evidence in the pulse; but it is a feeble contraction. In other cases, the ventricle does not perceptibly contract. Whether there is a very abortive contraction, or not, is doubtful. Certain it is, that in some cases the ventricular contraction can be detected when too feeble to produce a pulse wave; in other cases, no ventricular contraction can be perceived. Intimately connected with this condition, is true angina pectoris, and, finally, cessation in diastole.

After this brief *resumé*, we can now consider the mode of action of digitalis, in what manner it acts; and from that, again, get an idea of its therapeutical value.

[To be continued.]

## CASES OF PLEURITIC EFFUSION MARKED BY VERY FÆTID EXPECTORATION.\*

By JOHN C. THOROWGOOD, M.D.,

Assistant Physician to the Hospital for Diseases of the Chest, Victoria Park.

WHEN we read the descriptions of pleurisy given in our medical textbooks, we cannot well help coming to the conclusion that few diseases ought to be more easy of recognition than pleuritic effusion; and that any one who overlooks an effusion of fluid in the thorax, or who is unable to speak decidedly as to the cause of dulness on percussing the chest, must be quite behind the age in his medical knowledge.

Be this as it may, I expect I do not relate a marvel of medical experience when I say that I have known a case where the treatment of more than one competent man has been energetically directed to the patient's brain for the purpose of arresting convulsions, when after death this organ was found in every respect healthy, while the left side of the thorax was the seat of a well-marked diaphragmatic pleurisy, with copious deposition of lymph and effusion of fluid. This case was related to me by one of the attendants, himself an eye-witness of all the events. Incessant vomiting, followed by convulsions, drew all attention to the brain, and the chest was, it appears, entirely forgotten.

I have, doubtless like many others, been asked to see a case of continued fever, when an examination of the thorax has disclosed the novel fact of one side being dull as a brick from top to bottom. No complaint of pain in the side or of cough had ever been made, hence it had not been deemed necessary to examine the thorax.

In hospital out-patient practice, and in other than hospital practice, too, it is not rare to meet with patients who describe their symptoms in such a way as to lead us not to wonder when they tell us they have been told "it is all stomach" or "all liver", and yet examination shows us a thorax containing more or less of fluid effusion.

These matters teach us the importance of carefully examining every patient who may come under notice, and of not forgetting the precept of the late Matthew Baillie, that the physician, in his examination, should seek to turn his patient inside out before him.

Though ordinary painstaking care will do much to guard us against serious errors in the diagnosis of pleurisy with effusion, still there are forms of pleuritic effusion that come on so gradually and so imperceptibly, presenting also—prominently often—symptoms that we are accustomed to connect with other known forms of chronic pulmonary disease, that the correct diagnosis becomes a matter of peculiar difficulty.

The three cases of pleuritic effusion that I have made the subject of this paper, presented other than the ordinary signs of pleuritis, and hence seem worthy of notice.

In all the cases, the most marked and prominent symptom was extreme fetor in the expectoration. When the patient makes this his great cause of distress and complaint, the first thought of the physician may tend to old-standing bronchitis with dilated sacculated bronchial tubes, or to chronic phthisis with old cavities and more or less fibrosis, or fibrification, of the surrounding lung-tissue. In the following cases, none of these explanations could be assumed as correct.

CASE I.—Mrs. S., aged about 40, was seen with the late Dr. Cregeen of Rotherhithe on May 11th, 1867. She had been ill five weeks with pain in the right side and cough. Lately this cough had increased, and been attended with some rusty-coloured, very offensive, expectoration. The right side below was dull, and at some parts a distinct rubbing sound was heard; very little respiratory sound was heard. The pulse was 80; the skin was not hot; debility was great. Considering the duration of the illness, and the recent occurrence of the fetid sanious expectoration, I thought that there must be a subpleural abscess; and I told Dr. Cregeen that we might have hæmoptysis, pneumothorax, or both, as possible events of the future. On May 19th, the patient seemed dying, in a state of collapse, with shivering, profuse sweating, and finally very copious purulent expectoration. On May 21st, I saw her for the second time. She was better; pulse 88. The right side was dull; there was an ægophonic twang in the voice; a friction-sound was audible; there was no blood in the sputa. She gradually recovered. On May 7th, 1868, I examined the chest, and all that I noted was some impaired resonance on the right side and bronchial breathing. The treatment consisted of bark, with sulphuric acid and free nourishment. Carbolic acid made her faint, and she would not continue it.

CASE II.—The notes of this case are fragmentary. The patient was a man in the Victoria Park Hospital, with much cough and expectora-

\* An abstract of this paper was read before the Medical Society of London; and, in compliance with the expressed wish of the President, I here publish the paper in a more ample form.—J. C. T.

tion of very offensive sputa, rusty-brown in colour. The left side of the chest was dull, but some limited cavernous breathing was heard at parts. The heart beat in its usual position. This man had been long ill, and the case seemed one of cavities in the left lung, containing purulent offensive matter. On Sunday this man was in a state of great collapse and prostration, with copious fetid expectoration. On Monday he was better. On Wednesday he had rigors, clammy sweats, and very feeble pulse. On Thursday he died. The *post mortem* examination showed the left pleura quite full of stinking purulent matter, the lung being pressed back against the spine. There were some adhesions, and these were so arranged as to fix the pericardium and heart *in situ*. Had the adhesion been absent, the heart might have been pushed over to the right side and the diagnosis less obscure.

CASE III.—A respectable man engaged in a shop in Regent Street, aged 44, when seen by me at my house on August 1st, 1870, looked very sallow, but in no way emaciated; indeed, he said that he had been becoming rather corpulent of late. It seemed he had been ill about one month, and he believed he was suffering from stomach and liver derangement. He had a cough, and had been at the sea-side without deriving any benefit. My own faith in the restorative powers of pure sea-air in all complaints of mere exhaustion and debility is such that, when a patient returns from a month by the sea no better, or even worse, I suspect some seated disease in the system. The great complaint made by this man about his cough was, that for the whole month past he had, at times, coughed up sputum so offensive as to render the room in which he was quite unbearable. He had shortness of breathing; the pulse was 104; the tongue foul. An examination of the chest disclosed dullness at the right base up to the line of the nipple, and extending downwards a little below the ordinary limit of hepatic dullness. The respiration at the base of the right lung behind was bronchial, with some crepitation. In the left lung there was strong loud breathing. I advised him to inhale the fumes of carbolic acid from a vaporiser, and gave him quinine with dilute hydrochloric acid. A few days later, crepitation was marked at the right base, and a few crepitant rhonchi were heard at the left base also. Beneath the clavicle the respiration was weak. He went daily to his business. On August 12th, he called on me in great alarm on account of free hæmoptysis. An examination of the chest showed the breathing harsh and strong at both bases, and much less crepitant rhonchus. I told him to keep quiet at home, gave him opium at night, and creosote with acetic acid during the day. The fœtor of the expectoration had almost totally subsided since he had used the inhalation of the vapour of carbolic acid from one of Savory and Moore's carbolic acid vaporisers. On August 22nd he was taking iron and quinine; the pulse was 84. There was less dullness over the right base, but some pain at times on the right side; and he said he did not think I need see him again. A few days later, I left town for three weeks. I heard no more of him till October 1870, when he called in consequence of a sudden attack of hæmoptysis, after taking a long walk and eating raw apples. His pulse was 88. There was dullness still at the lower right third of the chest; the breathing was very weak now, where before it was bronchial. At the left base there was strong full respiration; the sputa were not fetid. This was on November 19th. I next saw him in bed, in consultation with Dr. Brown, his regular attendant, on Sunday, January 22nd of this year. He said that on the previous Thursday, as he left the omnibus to walk to his house at Camden Town, he felt sudden severe pain in the chest; and when I saw him I found him lying in bed on his back, with no severe dyspnoea, respiration 40, pulse 132. The right back was perfectly dull; and when I moved him and listened afterwards, a distinct metallic tinkle was heard. I considered that a subpleural abscess must have burst into the pleura, causing a false empyema. The dyspnoea being by no means urgent, I prescribed some ordinary remedies, and suggested that it might be well for me to see him again should his difficulty of breathing increase; my intention under these circumstances being to propose paracentesis of the right chest. A week later (Saturday evening), a message was left at my house that the patient was dead. I called on the following afternoon, prepared with instruments for a *post mortem* examination. Dr. Brown soon came, and we together made the examination. When Dr. Brown cut through the cartilages on the right side of the thorax, at once a puff of very foetid gas escaped; and on opening the chest the right side was full of stinking grumous purulent fluid, which I ladled out to the extent of a chamber-pot quite full. The right lung was then seen as a mere thin skin pressed against the spine, leathery, airless, covered with creamy pus, and on spreading it in a plate we could trace a cavity, or rather sac, in its lower lobe. The left lung was voluminous and congested. Nothing like a tubercle was seen in either lung. The liver was large, but not unhealthy. I was interested in this point, for the very basis character of the disease in the first instance, the fact of the right side being affected, the sallow, but by no means emaciated, look

of the patient, made me think more than once of the case of a man admitted to Victoria Park Hospital many years ago with profuse purulent expectoration, where a *post mortem* examination showed that an hepatic abscess had ruptured through the diaphragm and been discharged by the bronchial tubes. Against such a probability in the present instance I set the rarity of hepatic abscess, the rarity of its opening through the diaphragm, and the fact of the dullness increasing rather upwards towards the axilla than downwards towards the abdomen. With respect to remedial treatment, the inhalation of the carbolic acid vapour I may describe as strikingly beneficial against the fœtor, and the power of opium and also of digitalis over the attacks of hæmoptysis was unmistakably marked.

Inquiry into the early history of case III elicited nothing more definite than the statement that he had for a long time had cough and much expectoration every morning. Ulceration of the air-tubes must have taken place, soon after which event probably it was that the sputa became not only fetid, but mixed freely at times with blood. More than once during my attendance I mentioned this sequence of events as my opinion; and, in answer to inquiry, I decidedly negatived the idea of tubercle of the lung. During the last week of the patient's life, as well as for several weeks previously, there had been no return of the fœtor in the sputum, which was tough, and greenish at times. The large amount of fluid found in the right pleura seemed to have increased rapidly during the last week of life, and must have been caused by the lung-mischief extending from within outwards.

The prospects of paracentesis in these forms of pleuritic effusion and false empyema are not promising: the question, however, is one on which more practical experience is wanted. My own opinion would be favourable to the operation, as one that would rid the patient of a dangerous and pernicious matter within the chest, and would thus afford him, at any rate, a chance of recovery which he would hardly have while he was carrying about, pent within his chest, an accumulation of offensive fluid.

In conclusion, I may observe that the events which I mentioned as probable, or rather possible, in Case I—viz., hæmoptysis and pneumothorax, actually did occur in Case III. The prominent symptom of the fetid expectoration is the one to which I would especially draw attention in reference to its relation to these forms of pleuritis.

## EXFOLIATION OF THE BLADDER,

By T. SPENCER WELLS, F.R.C.S.,

Surgeon to the Queen's Household, and to the Samaritan Hospital.

DR. WARDELL'S interesting case reported in the JOURNAL of June 10th, with his paper and that of Dr. Phillips in succeeding numbers, have induced me to send to the museum of the College of Surgeons two specimens, which I have asked Mr. Flower to place where they may be conveniently inspected by any of the Fellows who may attend the College election next Thursday, and who may be interested in the subject. Another specimen (No. 1993 Pathological Specimen) in the museum referred to by Dr. Wardell, from the bladder of a man, which Mr. Liston opened by incision above the pubes, may be seen at the same time.

In one of my specimens, the uterus and bladder are seen, as well as the detached cast of the bladder, covered with a gritty deposit of urates and phosphates. The walls of the bladder are thick and contracted, the muscular fibres being distinctly visible. The detached mass which was lying loose in the bladder I described at the time as "degenerate epithelium holding together saline deposit." On boiling a piece of it in twenty parts of water to one part of acetic acid, much of the saline matter is dissolved, and some of the tissue becomes clear, looking like smooth muscular tissue which has begun to degenerate by the deposit of fatty or albuminous particles in its substance." (*Obstetrical Transactions*, vol. iii, p. 354).

The patient was twenty-two years of age. After a natural labour with her first child, the bladder was not emptied for sixty-two hours. Five pints of turbid bloody urine were then drawn off. Cystitis followed, incontinence of urine, and a train of distressing cerebral symptoms, ending in death two months after delivery.

The second specimen I exhibited at the Obstetrical Society on the evening of the day when it was voided by the patient, six weeks after a severe instrumental labour. The report may be seen in the third volume of the *Obstetrical Transactions*; and in the fourth volume there is an elaborate report on the specimen by Dr. Harley.

From the time of her labour the patient suffered from severe cystitis with nephritis. Three weeks after labour, the urine contained albumen, blood-corpuscles, pus-cells, chylous matter, and renal tube-casts.

The urine, when quite fresh, was loaded with carbonate of ammonia. A hard swelling had been felt through the anterior wall of the vagina; and on the day before the specimen was expelled through the urethra, Mr. Marshall, the surgeon in attendance, had observed shreds of sloughy membrane protruding through the urethra. After it came away, the health of the patient rapidly improved. I have lost sight of her; but Dr. Harley saw her in good health between two and three years after the illness.

My second specimen differs from the first in being a more complete exfoliation of the bladder. It is a bag of animal membrane—involuntary muscular fibres interlacing over its outer surface—the interior being a smooth mucous surface, covered with crystalline phosphates and urates.

The case referred to by Mr. T. Smith in the thirteenth volume of the *Pathological Transactions*, page 150, was, as I believe and said at the time, a similar case to these; but two very competent observers reported that they had “no doubt the membrane in question is the bladder of some animal, most probably that of the bullock; and that it has not been passed in the manner which the patient represented.”

It is evidently of great importance that the true nature of these cases should be recognised; for the recovery of my second patient would encourage us in a male patient to follow the example set by Mr. Liston, and remove the foreign body. In a female this might probably be done by forceps alone, and certainly if the urethra were previously dilated.

## CLINICAL MEMORANDA.

### CAN MERCURIAL TREMORS COEXIST WITH CHRONIC LEAD-POISONING?

THE two following cases may be interesting to the readers of the JOURNAL in regard to the above query.

George B., aged 26, a looking-glass silverer, came under my treatment in February last. He was a poorly nourished man, with a fair complexion, and was suffering at the time from severe muscular tremors. The muscles chiefly affected were those of the upper extremities; and in conjunction with the tremors there was great weakness of the muscles of the hands (especially of the extensors), so that he was totally unable to feed himself and perform various minor offices without assistance. With these symptoms pointing to the muscular system, he also had slight pyalism, sponginess of the gums, and great fetor of the breath. The anomalous part of this case, however, remains to be described. Along the edge of the gums surrounding the incisors of both jaws was a very distinct blue line; and in association with this phenomenon I may mention that he had griping pains in the abdomen, although the bowels were not greatly confined. He was treated with three-grain doses of the iodide of potassium three times daily, and was told to abstain from following his employment. I saw him afterwards at intervals of a week or ten days until May last. The muscular tremors, the fetor of the breath, and the sponginess of the gums, rapidly disappeared—not so, however, the blue line surrounding the incisors, and the partial paralysis of the extensors of the fore-arms: these symptoms still persisted, although in a modified degree, even at his last visit. In my inquiries concerning the nature of his employment, I elicited that the tin-foil used in silvering contained a considerable percentage of lead in its composition.

In May last, John C. came under my treatment suffering from colicky pains in the abdomen and constipated bowels. He had been employed for the last five years at tin-foil works. Upon examining his gums, I found a slight blue line beneath the lower incisors. There was no paralysis in this case. This patient also confirmed the statement of George B. as to the employment of lead in the manufacture of tin-foil. Cessation from work and small doses of Epsom salts, combined with diluted sulphuric acid, two or three times daily, rapidly relieved him.

From the symptoms present in the first case and their subsequent mode of retrogression, we must conclude, I think, that two poisons were simultaneously affecting the system; and, consequently, we must rather ascribe the blue gum line to the lead than to the mercury, although the black sulphide of the latter metal might, theoretically, be supposed to give rise to such a phenomenon.

53, Harley Street, W., June 19. W. AINSLIE HOLLIS, M.D.

THE fatal cases of small-pox in London, which in the three previous weeks had been 257, 229, and 245, were 240 last week. The fatal cases showed an increase in the East of London, a decline in the West and South, and but slight variation in the North and Central Districts.

## REPORTS

OF

### MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS OF GREAT BRITAIN.

#### NOTES ON THE TREATMENT OF GANGLION IN THE LONDON HOSPITALS.

THE treatment of the common affection called ganglion, simple as it may appear and is generally supposed to be, is still a subject on which a very considerable difference of opinion exists amongst surgeons, as may be seen by a perusal of the following notes. It was with the view of gathering the opinions of hospital surgeons on the various methods of treating this affection, that we thought of collecting a few notes on the subject. We have been by their kindness enabled to obtain a mass of valuable information, containing the experience of most of the London hospital surgeons; and shall endeavour to procure similar notes from provincial hospitals and from Scotland and Ireland. We shall be glad to receive at the same time short notes of interesting cases of ganglion, for publication, in connexion with our report on the general treatment of the affection.

#### KING'S COLLEGE HOSPITAL.

MR. JOHN WOOD treats ganglion by the following plan. A spear-pointed needle, cutting on both edges, and mounted on a handle, is passed into the cyst, and made to transfix it again and again, so as to let out the synovial contents into the areolar tissue of the surrounding fascia. The needle is then made to scarify briskly the interior of the cyst, and is used pretty freely in dividing the cyst-wall at its opening of communication with the sheath of the tendon. Pressure is then made with both thumbs upon the tumour, so as to squeeze out completely its contents, partly into the subcutaneous areolar tissue, and partly out through the opening in the skin by which the needle entered. Iodine paint is then applied thickly over the surface, and upon it a thick pad of lint, over which firm pressure is made by a bandage. This is kept on for several days, after which the iodine paint is again applied, and the pressure readjusted. After a few applications in this way, the tumour seldom reappears; and, if it do so, a repetition of the process rarely fails to succeed. No case has been met with, out of many hundreds treated, in which suppuration or any bad results have followed this plan; but several cases in which a seton had been employed have given rise to much trouble and danger from erysipelatous inflammation and abscesses, followed by stiffening, and in some cases permanent impairment of the use of the limb.

MR. HENRY SMITH meets with a large number of cases of ganglion in the out-patient department of the hospital. After having tried various means of cure, he has come to the conclusion that the most effectual is that of operation by the seton. He passes a single ligature-thread through the cyst, and allows it to remain according to circumstances. In some instances, severe inflammation and even suppuration will be produced in forty-eight hours, and then the thread is to be withdrawn. In the majority of instances, however, especially when patients are careful not to use their hand, the seton may be retained for a period varying from three days to a week or more, without producing any inconvenient symptoms; but, so soon as suppuration takes place, Mr. Smith withdraws the thread, and the cure is almost invariable. It is necessary to bear in mind in this treatment, that, in some constitutions and under certain conditions, the presence of the seton may produce very severe consequences; in fact, this is the only objection to the treatment. With care, this rarely occurs; and there has only been one instance amongst Mr. Smith's patients at the hospital where bad results did happen. This was in the case of an unhealthy man who applied with a ganglion as large as a crown-piece on the back of the wrist. Mr. Smith passed a seton. The patient did not apply until after four days, and in the meantime most violent inflammation and suppuration occurred. Free incisions were necessary, and the wrist-joint itself was threatened for a time; but the use of a splint and careful treatment prevented any mischief. The patient, however, was compelled to remain under treatment for several weeks.

MR. ROYES BELL often finds that a ganglion is too tough to be burst by any reasonable amount of external pressure, or is so situated that this form of treatment is not applicable; and that it may be radically cured by a puncture with a grooved needle, squeezing out the contents as perfectly as possible, and rubbing the sides of the cyst together. Firm pressure must be applied by means of a pad formed of lead, gutta

percha, or a piece of money, tightly strapped and bandaged over the site of the ganglion. Should this treatment not succeed, he prefers lacerating the walls of the ganglion subcutaneously with a strong needle with cutting edges, to the use of the seton. He has seen many excellent results follow this method, which is less severe than the seton, though the latter no doubt is the more radical form of treatment. He has seen a severe case of ganglion connected with the flexor tendons of the wrist, and passing with them under the annular ligament, cured by laceration. Mr. Bell has also evacuated a ganglion by means of an incision, squeezing it roughly, so as to get rid of all its contents. In this case, the ganglion returned. These swellings have a tendency to recur; and in weakly persons, after a radical cure of one, another and a fresh one may form. For ganglia which resist these simpler plans of treatment, the seton remains, which Mr. Bell thinks less manageable than the other methods. In passing a seton through a ganglion at the back of the wrist in an out-patient, he advises the hand and wrist to be placed on a straight splint for the time being. In the severe form affecting the flexor tendons under the annular ligament, the patient ought to be in hospital, under constant observation and control, as out-patients are proverbially careless. The after-treatment by carefully applied pressure, to be kept up for several weeks, is of considerable importance.

#### UNIVERSITY COLLEGE HOSPITAL.

Sir HENRY THOMPSON applies, for ordinary and recently formed ganglia about the wrist, tincture of iodine for four or six weeks, usually with good effect. If they resist this, he passes carefully through the centre, with a sharp needle, a double thread of silk; ties the two ends in a knot, squeezes out the contents by the needle-opening, and leaves the thread in for three days, applying water-dressing. At the end of that time, if a purulent discharge be seen, and a little inflammation have taken place, Sir Henry removes the thread, and applies water-dressing. Almost always, there is no more trouble with the ganglion. If little or no action be produced by means of the tiny seton, he leaves it in a day or two longer. Sir Henry has never had occasion to regret this but once. An out-patient at the hospital, who did not attend at the end of three days, returned a week after the operation with erysipelatous inflammation of the arm. She did badly, and got some permanent stiffness of the hand in consequence. That is the only unfortunate event among a great many cases which Sir Henry has thus treated; and, had he seen her at the end of the three days, he has no doubt all would have gone well.

Mr. CHRISTOPHER HEATH finds ganglion affecting the extensors of the wrist to be a common affection among the out-patients of University College Hospital, and readily amenable to treatment. If the cyst do not yield to the pressure of the thumb steadily exerted for a minute or two, Mr. Heath is in the habit of puncturing it with a grooved needle, and evacuating the jelly-like contents. He has never seen any harm result from the practice, and finds the subsequent application of iodine paint for a few days apparently prevent the refilling of the cyst. Ganglion of the extensor tendons on the back of the foot is by no means rare; and within the last few months Mr. Heath has seen the disease in more unusual situations—viz., deeply in the ball of the thumb, in connexion apparently with the tendon of the flexor longus pollicis; and again behind the external malleolus, in connexion with the peronei tendons. In both instances, a puncture settled the diagnosis and concluded the treatment simultaneously; in the latter case affording great relief to the mind of the patient, who had been assured by a leading authority on deformities that the tumour was fibrous, and would require a serious operation for its removal. In the compound ganglion of the flexors of the wrist, where the swelling forms above and below the annular ligament, and the fluid contains bodies like rice or melon-seeds, Mr. Heath has evacuated the fluid by a puncture, taking care to keep the hand on a splint; and when this has failed, as it generally does, to effect a cure, he has employed the seton with success.

#### ST. BARTHOLOMEW'S HOSPITAL.

Mr. SAYRE treats those sacs filled with glairy fluid, which are so apt to form about the wrists and hands, by puncture, complete evacuation of contents, and firm, equal, and continued pressure, as described by him in the second volume of *St. Bartholomew's Hospital Reports*, p. 79. Mr. Sayre treats ordinary cases of enlarged bursa over the patella and these ganglia in the same way.

Mr. THOMAS SMITH believes the best way to cure ganglion to be to rupture the cyst by forcible compression, if possible, (not by a sudden blow), and to keep a pad and bandage applied for some days afterwards. Even when the ganglion does not at first collapse, the effect of a hard pressure may be to cause gradual absorption. When the synovial cyst is too tough to be affected by the previous plan, he is in the habit of making a subcutaneous section of the entire cyst-wall with a

fine tenotomy-knife, and keeping up pressure for some days. If, from any objection on the part of the patient, or from other causes, this cannot be done, he has occasionally cured the disease by blistering with ointment of biniodide of mercury. He has no experience of injecting, excising, or passing setons through ganglia.

Of the treatment of ganglion (as distinct from the recognised bursar swellings) at St. Bartholomew's, Mr. WILLETT says that attention must first be drawn to the frequency with which this affection is met on the dorsal aspect of the wrist and hand. For its cure, Mr. Willett relies on forcible dispersion, either by rupture of the sac by the thumbs (which, by the way, requires dexterous manipulation, rather than any great amount of force), or, this failing, by puncture with a Paget's knife. But, whether the ganglion be ruptured or punctured, the essential element of success lies in the complete evacuation of the cyst's contents; and, to ensure this being done, tolerably rough handling in the way of pressing and squeezing the sac may be employed. Then the application of a compress of lint and roller completes the operation. Mr. Willett believes that, when dispersion fails, the reason is, that the operator has been content with simply rupturing the cyst; but, if proper care be only taken to empty the ganglion thoroughly, this plan of treatment may be regarded as almost invariably successful. With regard to the so-called ganglion affecting the sheath of the flexor tendons at the wrist, Mr. Willett coincides with the opinion that, should operative measures become necessary, it is advisable to lay open the swelling above the wrist tolerably freely.

#### GUY'S HOSPITAL.

Mr. POLAND adopts every possible variety of measure, with success and non-success. Puncturing and emptying out the contents, with subsequent pressure, has had very satisfactory results, but not always so; and when failure has resulted he has laid open the ganglion, with a cure resulting.

The treatment of ganglion which Mr. HOWSE adopts varies with the nature of the cyst. If it be small and the cyst-wall thin, he thinks that forcible compression, so as to produce rupture, will give the best results. If, however, it be a large thin-walled cyst, close under the skin, without the distinct outline which such tumours generally present—tending, in fact, to become diffused—then repeated blistering nearly always gets rid of the affection. In cases of the above description, which are only slowly amenable to the blistering treatment, the cure may be much expedited by puncturing the cyst. There are, however, a certain number of cases which are not curable by any of the above methods; where the cyst-wall is thick and not capable of being ruptured, or where it is situated under dense fascia, as in the palm of the hand. Such tumours are often complicated by the presence of a large number of "millet-seed bodies". These are, he thinks, best and most expeditiously treated by excision of the cyst in the antiseptic mode. The usual objection to this plan of treatment is the fear of diffuse inflammation supervening. The antiseptic method, however, entirely obviates this objection, and with its aid he has no fear of opening the sheaths of the tendons even extensively. In this operation, Mr. Howse has found it no objection that the whole of the cyst-wall cannot at all times be removed. In spite of its presence, the wound will generally close by adhesion, and not a drop of pus be found. Even in puncturing a ganglion he would generally adopt the antiseptic method, considering it safer so to do. In most cases Mr. Howse prefers excision of the cyst to injection with iodine or any other irritant, having once or twice seen a good deal of inflammation set up by its means. For the same reason, treatment by setons is, he believes, not a very safe mode of procedure.

Mr. DAVIES-COLLEY's usual practice has been to disperse ganglia by pressure; and, if they are too hard to be treated in this way, to dissect them.

#### ST. THOMAS'S HOSPITAL.

Mr. LE GROS CLARK treats ganglion when in the wrist by puncture subcutaneously with a narrow lancet, or broad, spear-shaped needle, and scratches the interior of the sac. He then presses out the contents beneath the skin, and subsequently applies a lead-compress for a few days. This rarely fails, is almost painless, and is, in his experience, unattended with risk. When on the hamstring muscles, over the great trochanter, etc., he finds repeated blistering the safest and most efficacious treatment, or a blister kept open with iodine-ointment. Opening these large ganglia is not unattended with risk. It is safer, if opening be intended, to blister first. On the front of the wrist, and extending into the palm, blistering may be tried. Mr. Clark has not often been successful when they are large in this position. If opened, it should be by a free incision in this position. He prefers this to seton. Mr. Clark has never injected a ganglion, nor has he found it necessary to dissect one out.

[To be continued.]

## REVIEWS AND NOTICES.

INVESTIGAÇÕES ESTATÍSTICAS SOBRE AS DOENÇAS E MORTALIDADE DO EXERCITO PORTUGUEZ NO PERIODO DO 1º DE JULHO DE 1861 ATE 31 DE DECEMBRO DE 1867. Pelo Dr. J. A. MARQUES, Cirurgião de brigada, etc. Pp. 125. Lisbon, 1871.\*

NOTE STATISTIQUE DES GRANDES OPERATIONS FAITES A L'HOPITAL DE SAINT JOSEPH PENDANT LES DOUZE DERNIÈRES ANNÉES. Par M. A. BARBOSA, Médecin du roi, etc. Pp. 38. Paris, 1868.†

PORTUGAL would seem to display a special talent for statistical work, if we may judge by the productions which occasionally reach us. There are none indeed that repay attention better. The literary labours of Dr. MARQUES, so well known by numerous notices in our journals, are not confined to this class of inquiry, but he shines in them with an uncommon lustre. The mortality of the Portuguese army stands at 12.2 per 1000 effective annually, or 12.7 including cases of sudden death brought into hospital, amounting to about ten year by year. This figure would show improvement. The army comprises a body of veterans which might be estimated at a tenth or fifteenth of the standing force, among whom the mortality runs as high as 48.1 per 1000. There are a sort of relief corps, pensioners or *reformados*, which break the process of invaliding. They show one death to 5.3 sick, a very high proportion. Typhoid fever and phthisis, which are the standing plagues of armies, display a considerable aggravation from town or garrison life; indeed, the general mortality is much affected by the same cause, being highest on the whole at Oporto and next so in Lisbon, where the invaliding is more brisk than at the former city. Typhoid fever is most rife in these two towns, and also, curiously enough, in Algarve, the most southern province of the kingdom. It has been of late chiefly confined to one military division—Lisbon, Leira, and Santarem. The average for the troops from this cause is 2.5 sick and 0.83 deaths annually for every 1000 effective. As regards phthisis, Lisbon, with a garrison of about a quarter of the army, sends a third of the cases; and Oporto, with a garrison amounting approximately to a fourteenth part of the army, sends as high a contribution as one-sixth, viz., at the rate of 15.6 cases diagnosed in hospital to 1000 of the effective annually; while in country districts the proportion is but 5.2 per 1000.

Of the work of Dr. BARBOSA we shall say less, as it is written in an idiom more accessible to the general reader. It shows great enterprise in the surgical field, and gives room for very valuable conclusions, which may serve to correct some of our more hastily formed judgments. The Saint Joseph hospital is on a vast plan. We are particularly pleased to see the tonic treatment of surgical disease appreciated and carried out to a fair extent. The circular form of amputation is chiefly performed in Lisbon, according to a method by which less surface is exposed than by other procedures, and favourable conditions for healing are ensured. The method is particularly described. A proceeding of dressing the wound, revived from old Portuguese surgery, is in favour with Dr. Barbosa. It consists of spirits of camphor applied to the raw surfaces: the proportions are, alcohol, 2; camphor, 1—something like the application used by Nélaton. We wish a lengthened career and a happy employment of their powers to these distinguished authors, who are both in the flower of their age and the full tide of social distinction.

## NOTES ON BOOKS.

THE language of panegyric has been almost exhausted in the various notices which have appeared of HOLMES's *System of Surgery*, of which the fifth volume of the second edition (Longmans) is now in our hands. It is in all respects worthy of its high reputation. It does not easily lend itself to other than very detailed criticism; but we may say that this edition has been vastly improved by revision in most instances. Dr. Burdon Sanderson's essay on Inflammation is a masterly performance. It is not altogether satisfactory, however, that this part of the *System of Surgery* should be due to the pen of a physician, and that the physician should be compelled to have recourse almost exclusively to German authorities in describing recent additions to our knowledge of this fundamental pathological process. There are some parts of the fifth volume which

strike us as not quite satisfactory. If Sir Ranald Martin could not easily find the time to give the much needed revision to his article on Hospital Construction, it would have been wise to find assistance for the purpose, as has been done in other cases. The section on Surgical Instruments is admirable—as a liberal and well deserved advertisement of Maw's catalogue—but has really very little other merit. It is a pity it is not left out altogether, or entirely rewritten. Some of the observations (as on stricture-instruments) are almost puerile, and others are positively misleading. We should not advise any one to use the ear-speculum after the fashion shown in the woodcut. There is still room, therefore, for improvement; and the work must always remain one of considerable inequality; but it is not the less one of the highest grade of general merit, and permanently honourable to British surgery. We congratulate Mr. Holmes on the decided improvement of his *magnum opus* in this second edition, and tender thanks to the publishers for the judicious liberality which they have shown in the enlargement and illustration of this important standard work.

The third edition of WARING'S *Practical Therapeutics* (Churchill) has been altered and improved with great judgment, so as to introduce a satisfactory account of new agents—chloral, apomorphia, nitrous oxide, carbolic acid, etc.—without adding to the bulk. These additions are made with remarkable skill in condensation. This little manual, alphabetically arranged, with an excellent "index of diseases", is one of the best manuals of therapeutics yet in existence. It belongs, however, to a class of medical literature which is open to vast improvement, and even to revolution.

FURNEAUX JORDAN'S *Treatment of Surgical Inflammations by a New Method, which greatly shortens their Duration* (Churchill), is a book which must be tested by experience. It is the surgical apotheosis of counterirritation, which recent medical writers have declared to be a method without reasonable explanation or proved success. Mr. Furneaux Jordan carries the principle and practice far beyond the limits assigned to it by Mr. Higginbottom. He uses counterirritation in all inflammations, and endeavours to establish the best place and method. He thinks it should always be applied "over the next or another vessel or vascular territory." He has studied the subject with diligence and with originality; and if other surgeons, bearing in mind the natural history of local inflammations and their natural tendency to resolution, arrive at conclusions confirmatory of those detailed here, Mr. Jordan will leave a name among those who have extended our therapeutical resources.

SPENCE'S *Lectures on Surgery* (Adam and Charles Black, Edinburgh) and BILLROTH'S *Surgical Pathology* (Appleton, New York; Lewis, London) supplement each other. The eminent surgeons of Edinburgh and Vienna have minds and methods essentially different. Billroth's work is eminently satisfactory as a treatise on the principles, and Spence's as a demonstration of the practice, of surgery. The histological and pathological groundwork of surgical science is laid down by Billroth with admirable clearness. He shows a perfect grasp of the value of the investigations whose results he sums up, and an excellent appreciation of their bearing on practice. His diagrams of specimens are numerous and valuable; and so are Spence's descriptions and plates of operations and reports of cases. Mr. Spence's lectures are eminently clinical, and the fruit of extensive and successful practice. Both books are destined for a wide popularity amongst surgeons; and, to be just, we must recommend the purchaser of the one not to be content without acquiring the other.

Dr. WEST'S *Lumleian Lectures on some Disorders of the Nervous System in Childhood* (Longmans, 1871) are in many respects marked by an eminently conservative and reserved mental character. Flowing in style and judicious in psychological criticism, they will indeed be read with pleasure and profit; but they are hardly so solid, original, or precise a contribution to medical literature as a little more pains would probably have enabled their author to deduce from the stores of a rich experience. There is a singular looseness of clinical phraseology throughout the text, and an almost incredible absence of precise pathology. The lectures treat of Epilepsy, Chorea, Paralysis, and Aphemia. But, for the author, Duchenne, Remak, Brown-Séquard, Broca, Hughlings Jackson, might never have written. This is to be regretted; for Dr. West displays in many passages a graphic power and keenness of observation which become and adorn precise erudition and exact clinical observation, such as we look for in a teacher of his reputation and ability addressing the mature intellects of his profession in the Lumleian course of lectures. It is not without regret that we write these few words of criticism of a monograph which sins chiefly in that it seems to aim at a far higher standard than it reaches.

\* Statistical Investigations on the Diseases and Mortality of the Portuguese Army, from 1st July 1861 to 31st December 1867 inclusive. By Dr. J. A. Marques, Surgeon of Brigade, etc. Pp. 125. Lisbon: 1871.

† Statistical Note on the Great Operations performed in the Hospital of Saint Joseph during the past Twelve Years. By M. A. Barbosa, Physician to the King, etc. Pp. 38. Paris: 1868.

THE Subscriptions to the Association for the year 1871 became due in advance on January 1st. All which are not already paid, should be forwarded to the General Secretary, Mr. T. Watkin Williams, 13, New Hall Street, Birmingham; or to the Secretaries of Branches.

## BRITISH MEDICAL JOURNAL.

SATURDAY, JULY 1ST, 1871.

### OUR LUNACY SYSTEMS.

III.

In a former article, it was asserted that the knowledge of insanity and its treatment amongst the members of the medical profession is imperfect in consequence of teachers of Practice of Physic ignoring this class of diseases in their regular courses of lectures, and from the absence of any means for its clinical study. In a modified degree, it is true that the acquaintance with general physic is not so extended and accurate as it might be on the part of asylum-physicians; and the reason for this is not far to seek, if we trace the career of those who undertake the speciality. The young graduate who proposes to himself to exercise his vocation amongst the insane proceeds to his duty directly from the schools. So, certainly, does the general practitioner, but with this difference, that the nature of the majority of the diseases he is called on to treat is pretty accurately known; rules and principles of practice are laid down for his guidance; and his duty to his patients is purely medical. The young asylum-physician, on the other hand, finds himself in a semi-medical atmosphere; the professional half being of not the most attractive nature; the administrative half presenting no slight attractions.

We all know that few men enter on general practice without a feeling of diffidence as to their power of combating the more common forms of disease. They have seen most of the graver, but few of the slighter and more frequent, ailments which beset humanity; and it is not till after a year or two's experience that they feel any degree of confidence in themselves. In these early years of responsible practice, the acumen of the physician is developed—a quality which no multiplication of lectures, no number of terms devoted to "walking" hospitals, can ever evolve. It is in the wider field of common every-day disease that those powers of observation and ratiocination are developed without which no man can take a high position in the world of medicine. There are no diseases which desiderate more thorough exercise of such powers than those comprised under the generic term insanity. Their pathogeny, etiology, and pathology are obscure and difficult of demonstration; symptoms of physical diseases are masked in consequence of impaired reflex action; the most dire and dangerous ailments may exist without one single definite indication; their history is generally imperfect; in fine, they call far louder than all others for that medical common sense, that power of putting this and that together (a rough way of expressing the terms diagnosis and prognosis), which alone can be acquired by a work-day knowledge of general medicine. This is a faculty which asylum work is most unlikely to develop in any man, unless he be possessed of an intuition above the common. It is not that there are no advantages; it is that there are positive obstructions in the way. A false and impotent nomenclature of the diseases which come under the observation of the alienistic neophyte serves in no small degree to impede his medical vision. A false glamour of metaphysics assists to delude him. He is called, or rather calls himself, a medico-psychologist. Of all the false euphemisms which hang about the speciality, none is more ridiculous or deluding than that which associates in terms the physician of insanity with psychology. It would be just as proper to call the doctor who treats dropsy a medico-hydrostatist, or the one who treats flatulence a medico-pneumatologist.

Superadded to these influences is the constant association with people

who are the subjects of very prominent and very peculiar symptoms. Unconsciously, the young man accepts these manifestations as actual forms of disease; and, following in the path of those who have gone before him, he treats them as such. Having no pathological basis to work upon, he adopts the psychological nomenclature, which is convenient in itself in so far as it saves trouble; and, to quote the words of Mr. Weller, "is easily adapted to the tastes and wishes of the speller". The much-vaunted moral treatment assumes a pre-eminent position in his mind, for he is encouraged—in fact it is one of his chief duties—to promote the employment and recreation of the patients, in which consists the principal article of the moral Pharmacopoeia. When amusement becomes a duty, it is wonderful how well that duty is performed. So dances (balls they are called), cricket-matches, croquet-parties, theatricals, concerts, and pic-nics, are planned and carried out by the assistants, and duly recorded in the annual reports in glorification of the moral treatment of insanity. We are very far from desirous of slighting this system of amusements; they are absolutely necessary for the mobs of chronic lunatics who crowd our public and private asylums. What we deprecate is, that the time of the junior medical officers should be frittered away in the performance of duties in no way connected with their profession, and which might well be delegated to lay officials. The recent and curable cases must and do suffer from the attention given to the recreations of the chronic and incurable. The character of our asylums as curative hospitals suffers, and the assistant-physicians gradually imbibe the principle that administration is their first and chief duty.

The twig is bent; and when the assistant becomes superintendent, his proclivities are less those of the doctor than those of the autocratic ruler. We are thankful to be able to say, however, that to this there are many honourable exceptions.

There are two distinct classes of asylum-doctors—the medical superintendent and the physician-superintendent. The first regards himself as an executive officer, whose chief duty is to supervise the working of the whole concern apart from his profession; the second considers himself primarily as a physician to a hospital for the cure of insanity, and as such looks on the treatment of his patients as his first and most important duty. The "medical superintendent" is the product of the monster asylum system; "the physician-superintendent" is being gradually developed from amongst those who are ardently longing to establish so-called psychiatric medicine on a rational basis. Well do we remember the words of a distinguished German medical philanthropist, who has worked hard and successfully for the amelioration of the condition of the insane in his own country and in this, and who has done yeoman service in disseminating liberal ideas as to the treatment of mental disease: "Ah, my good sir, you are good in your country as to asylums; you have the pleasant houses, the nice grounds, and you do not have the *camisole* much; but I do see much to complain of in your asylum-doctor. There are two kinds: one kind very few, the other kind very often. The first is a doctor. He tells me of his patients as if I were in a common hospital; the second tells me not of his patients. He shows me his asylum and its *ménage*, his farm, and his pigs, and then he pulls a bag of corn out of his pocket, and says, 'Look here, my wheat is 63 lbs. to the bushel', but he tells me not how many patients he cures in the hundred." In this he may have put the position rather strongly, yet not very far from the truth; for the actual individuals idealised by our foreign friend are the "medical superintendent", and the "physician superintendent". We have known many superintendents who have won their spurs as administrators or farmers, few who have gained *kudos* as physicians; and when the *kudos* has been great, the material advantage has been small.

The disproportion between the rewards of successful management and of successful medical work being so great, it is hardly necessary to add that the majority address themselves more to the former than to the latter, for it tells more quickly and more forcibly on committees and boards of justices, and brings a quicker return. The administrating superintendents are by no means reserved in the enunciation of their

theories; but lately we heard one, whose opinion bears great weight, state his opinion that the medical superintendent *ought* not to undertake the medical treatment of his patients—that that should be left to the assistant or assistants, and should be merely supervised and not materially interfered with by the senior, for that he (the superintendent) had quite enough to do in managing the whole concern and all connected with it, from the members of the committee downwards. If this be a right view of the position, what necessity is there for the superintendent being a medical man? The medical supervision of the assistants could be well enough performed by a visiting physician, and the administrative department might with perfect safety be committed to a layman. Is there anything more complicated in the management of a lunatic asylum than of a workhouse or prison? of a manufactory or other large commercial concern? If it be not a hospital, why have a physician as its ruler? Such establishments as we have instanced are worked by men specially bred to business. If an asylum is to be a business concern, why should not a business man be appointed to supervise it?

Most educated men understand the ordinary rules of hygiene. It does not take a lifetime to get up a knowledge of dietetics, nor yet to acquire those common-sense rules which guide the treatment of a crowd of pauper lunatics. There is nothing about the management of an asylum calling for more than the possession of ordinary tact and ability, *except the knowledge of medicine*. When the superintendent of an asylum sinks his medical below his administrative function, he abrogates the right of the institution to the title of hospital, and confers on it that of a prison for lunatics. As soon as he adopts this line of action he finds it necessary to produce some palpable evidence of the successful conduct of the asylum: this is best done by a goodly balance of money at the end of each year. To make money he must have patients (?), and those in no diminishing yearly ratio. No doubt all recent cases who get well (we do not say cured) are sent away as soon as possible; but the eye is dimmed to the fact that, of those who are not positively perfectly sane, very many might be discharged to their own homes. But the business must be kept up; a falling off of patients implies a falling off of revenue. An increase of profits does no harm to the medical superintendent.

Not only must the superintendent make the thing pay: he must keep up the style of the place, and, commensurately with its size, promote the magnificence of its entertainments, recreations, and furniture. Marble washhand-stands may be necessary and proper for pauper lunatics; damask curtains may have some direct effect on the demented; and expensive upholstery indicates a line of treatment. This we cannot see, any more than we can understand the propriety of the maintenance of brass bands and magnificent dancing-saloons. It has been our lot to hear Mozart's Masses played on a Sunday afternoon by a well conducted body of performers, for the amusement of some hundreds of paupers—who, however, were somewhat remotely placed for accurate hearing. We have seen some hundreds of the same class disporting themselves in a hall such as the county hunt never danced in, to the strains of a band such as the county hunt never danced to. The impression left on our mind was, that the lunatics would have preferred the squeak of a fiddle in a less sumptuous apartment, and that the whole exhibition was the *reductio ad absurdum* of the system. And so on with theatricals and fancy balls—wasted money on wasted minds. Give them what they like; give them the fiddle or the comic song; but Mozart by a brass band—the hearers cooped in an airing-court, and paying not half the attention they would have given to a grind-organ—was provocative of nought but sardonic laughter and contempt for the system.

Such absurdities are encouraged and fostered by authorities higher than the medical superintendents; who, however, would soon exercise their influence in modification, were they more thoroughly imbued with the medical sense. These amusements are not for the curable, so much as the incurable. The incurable retard the recovery of the curable, in that they deflect the mind of the physician from his special

duty, and cause him to mispend his energies in a popular but non-professional direction.

It is impossible within the limits of the present article to offer suggestions which might possibly lead to reform; they must be left to a more convenient season.

#### THE IRISH POOR-LAW SYSTEM.

THE Annual Report of the Irish Poor-law Commissioners, just published, is possessed of unusual interest. The introduction of a Poor-law medical relief system, based upon, but intended to be an improvement of, that which has already existed in Ireland for twenty years, is a subject that has for some time engaged the attention of most of the advanced Poor-law reformers of this country. In our remarks on Mr. Corrance's queries some weeks ago, we entered generally into the subject of the shortcomings of the Irish system and what was to be avoided in its introduction into England. We will now consider the advantages that have been derived from it, as set forth by the present Report, which is at once highly interesting and instructive.

Our readers are probably aware that the administration of poor-relief in England is limited to two classes—namely, those obtaining indoor relief in the various workhouses, and those in receipt of out-door relief. The recipients in England of any relief whatever in connexion with the Poor-law, whether medical or otherwise, become paupers. The cost per head in England for indoor relief, according to the last Report of the Poor-law Board, was £8:10; for out-door relief, £4:5. The number obtaining indoor relief was 157,740; out-door relief, 784,906. In Ireland, by the introduction of the Medical Charities Act of 1851, the poor were divided into three classes—namely, the indoor, or inmates of workhouses; the out-door recipients of Poor-law relief (both of these classes are paupers); and the recipients of Poor-law medical relief (these are distinctly, by Act of Parliament, not paupers). According to the Report of the Irish Commissioners now before us, the total number receiving out-door relief in Ireland for the year ending September 30th, 1870, was 53,885, at a cost of £59,181, or a little over £1 per head; and in the workhouse, 230,429, at a cost of less than £7 per head. Under the Medical Charities Act there were attended by the dispensary doctors 784,424 sick persons; and the total cost per head for medicines, rent of dispensaries, stationery, salaries of medical officers, apothecaries, midwives, vaccination, etc., was £129,936, or about 2s. 6d. per head. The number of inmates of workhouses has decreased during the year 1870 by 5,133. The number of persons obtaining out-door relief has increased by 4,602; and the Commissioners remark that “it is most probable that, as the country advances in prosperity, the out-door relief lists, which have steadily increased from 655 persons daily in 1855 to 25,363 in 1871, will continue to increase, subject though they are to certain limitations imposed by statute.” Under the Medical Charities Act, there was an increase for the last year of 1,694 dispensary cases, and of 7,403 attended at the homes of the patients. Although since the passing of the Medical Charities Act there has annually been an increased expenditure in the carrying out of this Act and the Vaccination Act, the decrease in the total poor-relief expenditure for the year 1870 was £7,681. The decrease of expenditure under the head of in-maintenance was £21,371, while the decrease in the number of persons relieved in the workhouses was 5,133. The total number admitted sick was 49,749, against 133,386 who were not sick, being a decrease of 4,270 as compared with the preceding year. The Parliamentary Grant for medical purposes for the year was £62,792. One of the objects of the Poor-law Medical Officers' Association is to have a similar amount removed from the rates, as Parliament pays but half of the medical expenses, and disease cannot be said to be localised.

An important suggestion is thrown out for the more effectual protection of Ireland against future invasions of epidemic disease. “Village hospitals should be attached to the dispensaries, and placed under the care of the dispensary doctor in each case”. These hospitals should com-

prise at least two wards for each sex, a ward being capable of containing from five to ten beds, according to the circumstances of the case. As regards the cost of these buildings, in the opinion of the Poor-law Commissioners, it should have a first claim on whatever surplus of the Irish Church Fund might become hereafter available for such uses.

During the last year, nineteen medical officers have obtained superannuation allowances, and in most cases receive two-thirds of their salaries—the highest award under the present merely permissive Act.

Under the head of vaccination, we find that the Poor-law medical officers vaccinated 140,220 individuals; and, according to the last Report of the Registrar-General of Births and Deaths (Ireland), the births for 1869 were 145,912. The country, therefore, must be very closely vaccinated; and the result is, that the total deaths from small-pox registered in Ireland for 1870, were only thirty-two. Most of these were traceable to, or caused by, importation.

During the year, one of the medical inspectors, Dr. Hill, to whose loss we referred at the time as being greatly deplored by all those gentlemen with whom, in the performance of his duties, he came into contact, was replaced by Dr. Burke, the dispensary doctor of the Islandcady District—a first step towards a system of promotion advocated by the Poor-law Medical Officers' Association at the time.

On turning to the statement of the dispensary districts, and reverting to the subject of the indiscriminate issue of dispensary tickets, we particularly draw attention to the outrageous facilities afforded for this abuse. We find that there are 14,668 members of Committees of Management, qualified to issue dispensary tickets to whom they please; that, besides these, there are an almost equal number of wardens; there are also about a thousand relieving officers; in fact, there are over thirty thousand irresponsible persons qualified at present to issue tickets to the eight hundred dispensary doctors, or about thirty-five for each. In Dublin South Union, they have one hundred and twelve each. Not only this, but many of these persons leave books of tickets signed, to be filled up by any one who chooses to do so—a member of the family, customer, clerk, shopboy, etc.; or very often they do not go to the trouble of signing at all, but expect it to be attended to nevertheless. This is a great abuse, and must be carefully watched in the introduction of a similar system into England. Of all these 784,424 tickets issued in 1870 to the dispensary doctors of Ireland, we find that but 532 were cancelled, showing the difficulty of getting over the flaw in the Medical Charities Act to which we before alluded—namely, that there is no definition of a "poor person" or scale of fees for those who are unable to pay one pound down.

The number of persons certified for as dangerous lunatics was 900; number of days' attendance at bridewells, 560; number of patients attended in houses of correction during the year, 332. These last three items are imposed on the Irish dispensary doctors "*without fee or reward*." There were 7,424 cases of scarlatina, 51 of small-pox, and 15,744 of fever, attended by these gentlemen during the year.

We have entered thus fully into the subject of the Poor-law medical relief in Ireland, as it is likely that the subject will be discussed in the House of Commons during the present session; and, as we have already said, it is one that affects directly one-half of the medical men of the United Kingdom and a very large number of our readers. We think it of importance that the matter, which is one of considerable intricacy, should be explained, as far as our space may permit. It may, in fact, be necessary to return to it.

SIR JOHN PARKINGTON has accepted the office of President of the Social Science Congress, to be held at Leeds in October next.

It is understood that Lord Belper will become President of University College, London, in the room of Mr. Grote, deceased.

A PERSON named G. M. Ranter puffs and sells for three shillings, under the name of "*lemonade for strengthening the memory*," a fluid mixture of about 30 grammes, containing 15 parts of phosphoric acid, 15 of glycerine, and 70 of water. This is sold in Vienna.

A NOTICE issued by the Admiralty states that news has been received from Rio de Janeiro that the health of that city was "very excellent".

DR. GAVIN MILROY leaves this country in a few days for Demerara, Trinidad, and other West Indian Islands, on an official mission. He is sent out by Government to undertake further investigations regarding that frightful scourge, leprosy.

THE latest news from Chili report the prevalence of cattle-plague. Meetings had been held to discuss the question—"Is cattle-disease transmissible to the human species through the digestive organs?" The Chilian medical faculty had advised carefully abstaining from eating the flesh and drinking the unboiled milk of infected cattle.

At the Westminster police-court last week, Mrs. Ann Allen, of Manor Street, Chelsea, was fined £5 for letting a room in which a person had been suffering from small-pox to another person, without the apartment having been previously properly disinfected. In default the defendant was sent to prison for six weeks.

A SHEFFIELD correspondent writes:—A "Sheffield Medico-Ethical Society" has lately been formed, "having for its object the suppression of illegal practitioners. As there are so many loop-holes in the 1858 Act, and as we are likely to have a Medical Bill next year, I consider the formation of the Society in question to be somewhat premature."

#### THE BROWN TRUST.

WE are enabled to state that the conditions necessary to the completion of this Trust by the University of London have now been fulfilled. The University has been placed in possession of an excellent site, and abundant funds are forthcoming to carry out the objects of the Trust by founding an institution for the reception and treatment of sick and diseased domestic animals, which will afford invaluable opportunities for the advance of our knowledge of their diseases and their relation to those of man—a subject of scientific and national importance.

#### DROPPING THE SUBJECT.

THE proceedings at the recent meeting of the Durham Board of Guardians illustrate the hopelessness of expecting proper sanitary action to be taken in the prevention of zymotic disease by such bodies, under the present state of the law. Three things were admitted—that there was "a great deal of small-pox in the town; that there was no adequate hospital-accommodation for the reception or isolation of the patients; and no conveyance for moving them". The rest of the discussion was a hopeless maze of suggestions for enabling the guardians to avoid doing anything, and for getting other committees and bodies more or less concerned under various sanitary acts to do something instead of them. The end was characteristic; the subject dropped, and the small-pox went its way triumphantly.

#### THE GENERAL HOSPITAL IN VIENNA.

THE following statistics will be interesting in connection with the articles on the German medical schools, which have lately appeared in this JOURNAL. The report for 1869 of the General Hospital in Vienna, containing 2,000 beds, shows that the number of patients admitted during the year was 20,214—12,789 males, and 7,425 females. The average mortality was 12.6 per cent. The maximum number of male patients in hospital at one time was 1,070 in December, and of females, 812 in January. The average duration of each patient's stay in hospital was thirty-one days. The total number of cases was 1,097 more than in 1868; the death-rate was nearly the same, having for ten years oscillated between 11.4 and 13.3, except in 1866, when cholera was prevalent, and the deaths amounted to 14.4 per cent. Among the cases were 792 of ileo-typhus or enteric fever, and 27 of exanthematic typhus; 332 of intermittent fever; 1,458 of pulmonary phthisis; three fatal cases of hydrophobia; and two of dissection-wound, which re-

covered. There were also four cases of cerebro-spinal meningitis, all in males; 729 of pneumonia, the disease affecting both lungs in 121 cases; 495 of gonorrhoea, 410 of syphilitic chancre, and 1,286 of secondary syphilis. Among the operations were 95 amputations, 36 resections, 187 cases of removal of tumours, 10 cases of lithotomy, and 9 of lithotripsy; 7 ovariectomy cases (of which 6 were fatal); 305 operations for cataract, and 249 iridectomies. The total expenses for the year amounted to 589,611 florins (about £56,470).

#### PHARMACY LEGISLATION.

A DEPUTATION of chemists and druggists from various parts of the kingdom, introduced by Mr. E. Baines, M.P., and accompanied by many members of the House of Commons, last week had an interview with the Right Hon. W. E. Forster at the Privy Council Office, to lay before him reasons why the amendment of the Pharmacy Act should be delayed until time has been given to consider the subject in all its bearings.

#### THE BERLIN EINZUG.

BEARING in mind the importance justly attached to the cases of sun-stroke in the "fatal marches" of last year, it is not uninteresting to note that our special correspondent in Berlin reports twelve cases of sun-stroke among the German troops at the *Einzug* or triumphal entry into Berlin; three cases being immediately fatal, and the others giving little promise of recovery. Prince Albrecht, the Emperor's brother, was seized with paralysis after leaving parade. Our correspondent—himself formerly a distinguished medical officer of the British army—observes, however, that the casualties amongst British troops subjected to similar fatigues, with their present clothing, would inevitably have been by far more numerous. He is struck by the want of "stiffness and smartness" of the men as compared with those of the *élite* of the British army; but, as a medical officer of a crack corps of British soldiers, and therefore accustomed to see the men "fall out by scores after an ordinary drill", he recognises the fact that in the German army "the best material is there, unhampered by the paralysing influence of over-tight clothes", so that, after a long and exhausting walk, and being more than ten hours under arms, the men mostly stepped along with a spirit and freshness which was surprising to him as a medical officer accustomed to watch a class of British troops in whom efficiency is still in no small degree sacrificed to tautness and smartness of equipment and clothing.

#### VACCINO-SYPHILIS.

THE Committee appointed by the Royal Medical and Chirurgical Society to investigate the cases recently brought forward by Mr. Jonathan Hutchinson, in which symptoms apparently syphilitic had followed vaccination, presented their report at the meeting of the Society on Tuesday evening. The report stated that the Committee had examined the vaccinator and several of the vaccinated persons in each series of cases—those related by Mr. Hutchinson at the meeting on April 25th, and those brought under his notice by Mr. Waren Tay and reported to the Society at the adjourned discussion on May 9th. An account of the appearances presented by the several individuals examined was given. With regard to the first series, the Committee stated that at the date of their examination, on May 16th, there were no symptoms of constitutional syphilis, and there was not conclusive evidence of the conveyance of the disease by vaccination. As to the cases in the second category, they considered that there were distinct evidences of constitutional syphilis in the persons vaccinated. With regard to the fluid used in vaccination, they had been unable to obtain any further evidence than that which had been given to the Society by Mr. Hutchinson.

#### A VICTIM OF GEIST.

THE Vienna newspapers report a remarkable and startling trial for mal-praxis, which presents considerable interest. A surgeon, sixty-three years of age, in a case of difficult labour, proceeded, after waiting a couple of hours, to deliver by means of a bent lever. After great exertion, which bathed the doctor in sweat, the child was brought to light

with injuries inflicted on the head, which, according to the official jurist, had caused death. The court submitted that the use of the instrument was unjustifiable according to the opinions now taught; to which the doctor vainly retorted that the instrument had been recommended to him in the year 1832 by the then professor, and that he had since used it frequently with success. The court decided that he should be deprived of his licence to practise midwifery till such time as he should prove by a new examination that he had made up his way in professional knowledge. The judge offered some very admirable advice to the unfortunate practitioner, observing that when a man devotes himself to a branch of science or of art he dare not remain stationary, but he must advance with the spirit of the time and keep pace with the progress of science.

#### SMALL-POX IN FLORENCE.

FROM May 20th to June 10th there were 134 cases of small-pox in Florence, with 12 deaths. Eighteen patients suffering from the disease were a few days ago in the Hospital of S. Maria Nuova. Our contemporary *L'Imparziale* urgently protests against this, as the hospital is a general one, and is situated in a thickly populated part of the city.

#### MESMERISM AND ABORTION.

AT the Lambeth Police Court, on the 22nd June, Charles de Badderley, described as a medical botanist, and Sarah, his wife, residing at Exeter Villas, Kennington, were brought up on remand, charged with selling various noxious drugs, knowing that the same were to be used in order to procure abortion. Mr. Poland prosecuted; and Mr. Fullagar defended the prisoners. The attention of the authorities having been drawn to an advertisement stating that "the celebrated Madame de Badderley, clairvoyante, could be consulted daily at 4, Exeter Villas", they placed the matter in the hands of Inspector Clarke, of the Detective Department, for investigation. That officer employed a woman named Hansard to go to the address given, and, representing herself as the aunt of a young woman who had got into trouble, to ask for something which should induce a miscarriage. On the occasion of Mrs. Hansard's first visit, the female prisoner said she could say nothing until put into a state of clairvoyance by her husband. This was agreed to; and the male prisoner, having made several passes with his hands, declared Madame to be asleep. After some conversation, the female prisoner was recovered from her supposed clairvoyant state, and then gave Mrs. Hansard some pills and herbs for the niece, charging half a guinea for them. A second visit was paid, at which the same kind of formality was gone through, and more herbs given to Mrs. Hansard, who again paid half a guinea. It was, however, stated by the female prisoner that, when in the mesmeric condition, she had discovered that the case was a very critical one, but that she could give some effective medicine for £5. Accordingly, Mrs. Hansard took a £5 note, marked by Inspector Clarke, and, on paying it to the prisoners, received from them some powders and other medicine. On analysis, they were found to contain injurious and powerful drugs. Mr. Ellison sent the case to trial at the Central Criminal Court, but consented to take bail of £150 for each.

#### DR. PANTALEONI.

AN action for libel was tried some days ago in the Bail Court before Mr. Justice Lush, in which the plaintiff was the well-known Italian physician Dr. Pantaleoni, and the defendant Dr. Vaughan, proprietor of the *Tablet*, a Roman Catholic newspaper. The gist of the libel was that Dr. Pantaleoni had taken two surgeons from the galleys, to which they had been sentenced for attempted murder, and reinstated them in the San Gennaro Hospital. Dr. Pantaleoni informed the editor that he was exiled from Rome at the time alluded to, and knew nothing of the matter. The *Tablet* persisted in the truth of the assertion, and hence the action. Dr. Vaughan withdrew the libel, for which he admitted there was no foundation, and apologised. A verdict was then taken for the plaintiff by consent—damages £250, to cover costs.

## ACTION OF IODATE OF POTASSIUM.

ACCORDING to M. Melsens, the poisonous action of even comparatively small doses of iodate of potassium cannot be merely due to chemical action—that is to say, to a kind of combustion, whereby organic matter present in the body of animals is destroyed. It appears that the centres of the nervous system are acted upon in a peculiar manner, and that the organised structure of the blood is destroyed, that liquid itself becoming chemically altered at the same time.

## THE SPREAD OF SMALL-POX.

A DEPUTATION from the National Association for the Promotion of Social Science waited on the Marquis of Ripon on Tuesday last, to urge the Government to put into force the Diseases Prevention Act, 1855, with a view to the suppression of small-pox. The following gentlemen were present:—Dr. Brewer, Dr. Lankester, Dr. Mouat (Bengal), Dr. Bain, Dr. Sarvis, Dr. Stewart, Dr. Hardwicke, Dr. Ramsay, Dr. Wyld, Dr. Ballard, Mr. Liddle, and Mr. Pearce, Secretary to the Association. The Marquis of Ripon, having been addressed by the deputation, said that the observations to which he had listened were exceedingly interesting, although they tended rather to the amendment of the law than the putting in force the provisions of the Act in question. With regard to carrying out the latter object, he thought it would be the means of giving them all the power which was desirable. He might say, in reference to a point touched on by Dr. Lankester as to the appointment of vaccination officers and a more complete isolation of cases, that Government had at present before Parliament a Bill which tended in that direction. The law at present made it optional; but in the Bill before Parliament it was intended to make it compulsory. He hoped that the Bill would be passed in the present session. Of course in all these cases it was necessary to regard public opinion. Many persons considered attempts of this kind an infringement on their private rights. Most unreasonable observations had been made in reference to the carrying out of the Vaccination Act. That very fact showed the necessity of proceeding carefully and with deliberation. He assured the deputation that their observations should have the most careful and anxious consideration.

## SPURIOUS TEA.

THE subject of the importation into this country of spurious and unwholesome tea again engaged the attention of the City Commissioners of Sewers at a recent meeting. The Sanitary Committee, to whom the matter had been referred, reported that, after inquiring into the proceedings which had been instituted by them in similar cases in 1866 and 1870, and the unsatisfactory results of the various efforts made to bring the offending parties within the power of the law, they deemed it useless to attempt any like proceedings against the persons who had offered the spurious tea for sale last month. They accordingly determined to lay the matter before the President of the Board of Trade; and, at an interview with him, they endeavoured to impress upon him the necessity for empowering the Customs' officials to take steps for the seizure and destruction of spurious tea, on receiving a certificate from persons duly authorised that it was unfit for human food. Mr. Chebester Fortescue, after affording them every opportunity for the expression of their opinions, requested them to furnish him with a written statement of all the facts in connection with the previous cases, and with copies of the reports of the solicitor and medical officer of health, which they had done. These, the Committee believed, were required to be submitted by the President to the Treasury for consideration; and they hoped in the end such steps would be taken by the Government as would put a stop to the discreditable traffic which still continued—a large cargo of rotten tea having recently arrived in London under consignment to various persons for sale in this country. Mr. Daw, the chief clerk, read a communication to the effect that, on the 21st instant, a ship arrived in the docks from Shanghai with five thousand chests of the mixture. The Commissioners approved of the steps taken by the Committee, and referred the matter to them for further consideration.

## THE STRASBOURG SCHOOL.

LYONS is not, it seems, to gain without contest the honour of reviving the Strasbourg School for France. A claim on behalf of Nancy has been put in; and several deputies of the east and north-east have laid before the National Assembly a Bill for transferring to that town the several faculties of the Strasbourg University.

## WESTERN COUNTIES IDIOT ASYLUM.

Mr. GIBBS of Tyntesfield, near Bristol, has offered £1000 towards the sum required for commencing the building on condition that £600—the additional amount required—be collected by Michaelmas. Dr. Blackall, and Mr. Divett of Bovey Tracey, have each contributed £50 towards this object.

## WESTMINSTER HOSPITAL.

THE vacancy which will be caused by the translation of Mr. Francis Mason to St. Thomas's Hospital will not be declared until Mr. Mason has formally sent in his resignation.

## CHILDREN'S HOSPITAL, BIRMINGHAM.

DR. JAMES SAWYER and Dr. Edward Mackey have been appointed Extra Acting Physicians to this Hospital, and Mr. D. C. Lloyd Owen has been appointed Ophthalmic Surgeon to the Institution.

## ST. MARY'S HOSPITAL.

WE understand that the medical Staff of St. Mary's Hospital have agreed to support the candidature of Dr. Nunneley for the appointment of Assistant-Physician. The other candidates will, it is expected, now retire. Mr. Owen, who was the only candidate for the vacant Assistant-Surgeoncy, has been recommended for election. Mr. Howard Hayward, Assistant Dental Surgeon, will be elected to fill the vacancy caused by the retirement of Mr. Sercombe from the Hospital.

## ST. GEORGE'S HOSPITAL.

IT has been decided by the authorities of St. George's Hospital to cancel the appointment of Resident Medical Officer, lately rendered vacant by the resignation of Dr. Jones. There will be two resident house-physicians instead of one as heretofore. No change will, however, be made in the appointments of house-surgeon; there will be two as before. The salary voted for the Resident Medical Officer will now go towards defraying the cost of the resident appointments, for each of which the sum of fifty pounds was previously charged.

## INDIAN MEDICAL NEWS.

THE reports of severe inroads of cholera in Cashmere are, says the *Homeward Mail*, unfounded. There have been no signs of the epidemic in the Happy Valley. Cholera has, however, made its appearance at Allahabad, where small-pox and measles are also prevalent. At the instance of the Inspector-General of the Indian Medical Department, the Government of India has decided to appoint supernumerary assistant-surgeons to officiate for permanent uncovenanted medical officers in civil stations.

## THE CONJOINT EXAMINATIONS.

THE Conjoint Examination Committees are continuing their work, and will meet again this (Friday) evening at the Royal College of Physicians. If they could succeed in completing their scheme before the conclusion of the session of the General Medical Council, it would redound alike to the credit and advantage of the corporations. If these negotiations should fail, the responsibility which will weigh on those who may cause the failure will be heavy, and will not be forgotten by the profession or the Government in the day of reckoning. Every consideration of duty, wisdom, and interest, should induce the English corporations to compose their differences, and, by a system of wise concession, to adjust their difficulties. An uniform minimum examination is the inevitable freight of time, and by arranging it among themselves the corporations are likely to fare better than in a less elastic arrangement which may be, and no doubt will be by and bye, forced upon them.

## THE UNIVERSITY OF LONDON.

It is a curious answer to disappointed parents and certain of our contemporaries who take exception to the severity of the preliminary examinations of the University of London, that six hundred and twenty-six gentlemen have entered for the matriculation examination now going on at Burlington Gardens—a number which, notwithstanding the popularity of the examination for some years, has never been at all equalled. It is, indeed, a fact that the percentage of rejected candidates, large as it is at the University of London, is below the preliminary examination of the much maligned College of Surgeons. There is, of course, a very considerable difference between the two examinations, as to the standard and variety of knowledge required; but it always has been the object of the University of London to encourage, and it has always required, a specially high and varied preliminary examination. It has aimed at ensuring a sound general education at the outset amongst those who aspire to its honours, and has set its face against the special study of a few subjects only, to the exclusion of others considered to be highly desirable. That the result has been acknowledged to be satisfactory, the very large and increasing numbers entering for the matriculation examinations bear ample testimony.

## THE BRIDGEWATER VACCINATION CASE.

At the Quarter Sessions held last week at Bridgewater, before the Recorder, Ernest Reed, Esq., Bovett and Roberts were each fined £5, having been adjudged guilty of misdemeanour in not attending to the summonses of the Mayor and refusing to have their children vaccinated. A demurrer was pleaded by Mr. Murch for Bovett. No appeal was allowed.

## THE SMALL-POX EPIDEMIC.

DR. LANKESTER recommends that a short Act of Parliament could be passed to meet the necessity of the case. Such an Act should provide for compulsory vaccination and revaccination, under proper superintendence, of every person in a town or district where small-pox is known to exist. A small-pox officer should be appointed for every town or district, whose duty it should be to isolate every case of small-pox, and superintend the disinfecting of the house where small-pox occurs. Wherever small-pox breaks out, the occupier of the house or the medical attendant should declare the existence of the disease to the small-pox officer.

## THE THEORY AND PRACTICE OF SKIN-GRAFTING.

At a meeting of the County Medical Society of New York (reported in the *New York Medical Journal*, April 1871), Dr. Benjamin Howard presented a case in which he had practised grafting with success for the healing of an extensive ulcer of seven years' standing, the result of a grape-shot which carried away the calf of the leg. Dr. Howard observed that in the reports which he had read all seemed agreed on one point, that epithelial cells in the graft are an essential element of success.

To aid in determining the correctness of this view, he had conceived the experiment of ingrafting a tissue which should contain no epithelium. Therefore, finding a few days previously that the reparative action in the wound seemed to be arrested, he, with the assistance of Dr. Hinton, had excised a piece of muscle from the middle of the biceps of the patient's arm, cut it into three pieces, about the size of the skin-grafts before used, and implanted them in the ulcer, just as those had been implanted. On examination twenty-four hours afterwards, each piece was found completely and firmly adherent in the bed cut for it, and was level with the surrounding surface. The whole surface of the wound had already taken on a new action, and covered itself with florid granulations. The edges had shared the fresh impulse; and even a part of the ulcer completely cut off from that portion where the muscle-grafting was made, by a bridge of cicatricial tissue, had felt the same stimulus and begun afresh the process of healing. From this moment the progress of the cicatrization had been as marked as when the skin-grafts were employed. The doctor wished to inquire whether the acceleration of the process of repair, so noticeable in the original margins of the ulcer, might not be due less to the *quality of the tissue* introduced than to the

*vital process of adhesion* established at a given point in the sluggish wound, which became a centre of increased vitality to the surrounding parts. Dr. Stein thought that the credit apparently due to the muscle-grafts ought to be given to the skin-grafts previously used. He had himself succeeded by simply sprinkling epithelial scales, some of which, doubtless, were not wholly deprived of germinal matter, over the surface of an ulcer.

## OVERCROWDING AND MORTALITY.

THE valuable report of Dr. Trench on overcrowding as a cause of mortality has had practical results. The Earl of Derby presided lately at a meeting held at Liverpool for the purpose of forming a society for the erection of labourers' dwellings on a self-supporting basis. In opening the proceedings, the noble earl said that the excessive disease and mortality of Liverpool were chiefly due to overcrowding, it being estimated that no less than one-third of the population lived, in average families of six, in single rooms. He thought that the evils of drunkenness would be obviated much more effectually by the erection of better houses for the labouring population than by teetotal lecturing, for the discomfort experienced by men and women from overcrowding was generally the incentive to drunkenness. One most satisfactory feature of the society was, that the tenants would pay a fair rent, and thus their self-respect would not be lessened by any consciousness of living in almshouses. From his experience of such societies in London, Lord Derby anticipated very favourable results to the new society. In this anticipation, we have furnished grounds for inducing our readers to join. We may again refer to some figures and observations on this subject in the *JOURNAL* of April 15th, and repeat the appeal then made to our readers to use their local influence in this direction.

## SCOTLAND.

DR. ALLEN THOMSON, Professor of Anatomy in the University of Glasgow, will preside over the Section of Biology at the annual meeting of the British Association for the Advancement of Science, to be held in Edinburgh in August.

## DR. CHRISTISON.

DR. CHRISTISON'S bust, which Mr. Brodie has just completed, was to be presented on Thursday to the Chancellor and Senatus of the University of Edinburgh in the upper hall of the College Library. It is intended to present a replica of the bust to Dr. Christison's family.

## ANNUAL REPORT OF THE COMMISSIONER IN LUNACY FOR SCOTLAND.

THE thirteenth Annual Report of the Board of Lunacy has been issued. The total number of lunatics in Scotland, of whom there was official cognisance on January 1st, 1871, was 7571; of these 1295 were maintained from private sources, 6227 by parochial rates, and 49 by the state. But there were some 2000 additional insane persons maintained by their friends in private dwellings. Altogether since 1858 there has been an increase of 1664, either to be ascribed to the growth of lunacy or the increased number of lunatics in asylums. On an average of ten years, 1861 to 1870, of every 100 patients sent to asylums, 26.1 were private and 73.9 pauper. In ten years the proportion of pauper lunatics in the general population has increased from 180 to 202 in every 100,000. In the whole of Scotland the total expenditure has increased more than a third. The total number of patients relieved during 1870 was 7284. The mortality of patients in private dwelling houses was 5.6 per cent. against 8.2 per cent. in public asylums, 8.9 in private asylums, 10.2 in parochial asylums, and 8.7 per cent. in lunatic wards of poorhouses. The Commissioners express the opinion that many patients are unnecessarily if not improperly sent to asylums. Of the accidents, fractured bones and dislocations occurred in 26 cases, from falls or from struggles with other patients or with attendants.

## BABY-FARMING IN SCOTLAND.

THE Select Committee of the House of Commons appointed to inquire into the subject of baby-farming met a few days ago, under the chairmanship of Mr. Walpole, when evidence as to Scotland was given. Mr. W. Cameron said he had closely investigated the question of baby-farming, both in Edinburgh and Glasgow, and the result of his inquiries was that he believed the rate of infant mortality was largely increased by the negligence of those who undertook the care of children. Baby-farming prevailed in both towns to a very large extent, and he invariably found that the children were in a squalid, miserable, and emaciated condition, without proper food, and sometimes without a bed to lie upon; while the nurses, in many cases, lived a life of gross intemperance. In one house at Portobello he found eight children under the care of two old women, and he had reason to believe that there were many similar cases in Scotland. There was the greatest difficulty in getting access to those houses unless, as was the case with him, he led the occupants to infer that he was there for the purpose of doing business with them. He had no hesitation in saying that children were taken in with the deliberate intention that, by a course of neglect, their lives should be sacrificed; and, as in many cases a lump sum was paid down to the baby-farmer, this result was not long delayed. Dr. Cameron, of Glasgow, gave similar evidence. He expressed his belief that there was a great deal of criminal or culpable neglect which resulted in the death of the children which were accepted by baby-farmers. In cases where weekly payments were made for the children, it invariably happened that the amount paid was not sufficient to provide healthy food, and the child therefore had to put up with unwholesome food until it succumbed. The procuration of abortion prevailed very largely in Scotland, particularly in Glasgow; and he urged the necessity of compelling the registration of still-born children, and a system of inspection of all houses where children were taken in to nurse. The inquiry was adjourned.

## IRELAND.

THE Surgical Travelling Prize has been this year awarded in the School of Physic of Trinity College, Dublin.

THE degree of LL.D., *honoris causa*, was on Wednesday, the 28th June, conferred by the University of Dublin on Mr. Charles Lever, the novelist, who graduated as Bachelor of Medicine of the University in the year 1831.

## THE NEW QUALIFICATION IN STATE MEDICINE.

THE first examination under the new regulations of the University of Dublin for granting qualifications in State Medicine, was held on June 12th, 13th, and 14th, when four candidates, Mr. Moore, Dr. Foot, Mr. Yeo, and Mr. Todhunter, presented themselves and passed. The examination papers contained questions in Law, Hygiene, Chemistry, Vital Statistics, Medical Jurisprudence, Meteorology, Pathology, Engineering, and State Medicine. The institution of this examination does great honour to the University of Dublin; and it is to be hoped that the example thus set will be followed by the other Universities of the United Kingdom.

## DR. GORDON AND "A CONSULTING PHYSICIAN".

DR. GORDON, of Dublin, charges our "nameless correspondent" of last week, "A Consulting Physician," with misquoting his letter of June 10th, and therefore thinks it right to state for himself that "he has never on any occasion knowingly consulted with any unqualified practitioner." Our "nameless correspondent" is "a consulting physician", as he signs himself, and of the very highest official, scientific, and personal position. If he preferred appending a general designation rather than his personal signature (which, of course, he forwarded to us), it was probably because he considered himself to be making a protest in the name of the class to which he belongs against the particular statement which he conceived Dr. Gordon to make. It was certainly not part of his or our intention to "vilify the profession in Dublin"; and,

if Dr. Gordon desires his name, we have no doubt that he will be perfectly ready to give it. We very readily give publicity to Dr. Gordon's statement that, "in all matters of medical etiquette, the Irish branch of the medical profession is immeasurably in advance of the profession in England;" and that "such matters as partnerships, club-attendances for sixpence or threepence a head, and all such other trade-partnerships as are every week to be found in the pages of the JOURNAL, are utterly unknown to respectable practitioners in Ireland". His first letter on the subject of irregular consultations was therefore the more unfortunate, and he owes us thanks for giving him the opportunity of presenting this more accurate and favourable picture of the facts, which he was previously less happy in depicting. His present sketch does, indeed, entirely accord with that honourable and brilliant picture of the status of the profession in Ireland which we have always drawn. The letter of "A Consulting Physician" is an evidence how much the statements of Dr. Gordon in his first letter were calculated to give an erroneous impression; and, in presenting his present correction, we purposely avoid printing some expressions accompanying them which might easily induce an irritating controversy.

## ROYAL IRISH ACADEMY.

At a meeting of this Society, held on the evening of the 8th of May last, the Rev. J. H. Jellett, B.D., Senior Fellow of Trinity College, Dublin, President, in the Chair, Dr. J. M. Purser read the second part of his Report on the Researches of Professor Cohnheim on Inflammation and Suppuration. That distinguished physiologist believes that the two following propositions are established as the result of his investigations. 1. In an inflamed part, the white corpuscles of the blood pass through the walls of the vessels in great numbers, and, having become free in the tissue, constitute the cells of pus. 2. The cells of the inflamed part itself have no share in the formation of pus; they persist for a time unchanged among the emigrated blood-corpuscles, and, if the inflammation last long enough, or attain a great intensity, they undergo a series of changes of a purely regressive or degenerative nature, ending in their death or destruction. Dr. Purser, in the first part of his report, read twelve months since, stated that his own observations fully bore out Professor Cohnheim's views as enunciated in the first of the above-quoted propositions. So far back as the year 1846, Dr. Augustus Waller had described the passage of the leucocytes of the blood through the walls of the vessels. With regard to the second proposition of the German physiologist, however, Dr. Purser found that the experiments conducted by himself gave negative results, and in them he was borne out by the opinions of Virchow and of Goodsir. Having described Professor Cohnheim's mode of procedure in experimenting on the corneæ and tongues of frogs, Dr. Purser proceeded to give in detail the results which he had himself obtained. His observations were also made on the corneæ and tongues of frogs. Inflammation was excited either by cauterisation with nitrate of silver, or by the insertion of a seton. In some instances, the occurrence of a spontaneous ulcerative keratitis obviated the necessity of causing irritation. Phenomena, essentially the same in kind, but varying much in degree and as to the time of their development, showed themselves in every case. On no occasion did the connective tissue-cells remain unaltered among the pus-corpuscles. The first well-marked change observed in the former consisted in a tendency to become elongated, and, in doing so, to lose their equally stellate shape. Their nuclei underwent a similar modification of form, and the protoplasm assumed a more decidedly granular appearance than in health. In the next stage of the inflammatory process, the cells have completely lost their primitive form, and have become perfect spindle-shaped bodies, while the number of nuclei increased, and amounted sometimes to four or more in a single cell. The third change consisted in the division of the spindle-shaped corpuscles. These first assumed an hour-glass appearance, and finally divided across in one or more than one place. Sometimes the spindles did not divide, but formed movable, multi-nucleated masses, like those described by Stricker. Dr. Purser believed, too, that the researches of this physiologist on inflammation confirm his own observations.

## THE EVOLUTION OF DISEASE.

MR. S. MESSENGER BRADLEY of Manchester writes:—In your editorial comments last week upon Professor Tyndall's recent lecture on "Dust and Disease", you point out the mistake which the lecturer makes in taking the No-man's-land of the *Origin of Life* for the legitimate possession of the vitalists; and, in a few pregnant sentences, show that the doctrine which he treats in quite an axiomatic way, of "the immutability of disease", is really not only unproved, but likely soon to be altogether disproved. Will you permit me to add to your remarks some arguments which, I think, tend to prove that diseases are indeed subject to the same law of gradual evolution which dominate the animate creation? For obvious reasons I only speak now of contagious and confessedly transmissible diseases.

The arguments in favour of the evolution of disease may be ranged under six heads. 1. Well-defined diseases present many prominent and important changes in different epidemics. 2. New diseases appear during epidemics from time to time, which ever after assume a persistent type. 3. The same transmitted disease sometimes differs in its manifestations in parent and child. 4. Zymotic diseases are correlated. 5. Diseases are sometimes artificially induced, which afterwards become hereditarily transmissible. 6. It is demonstrated, in one instance, that the same poison-germ, or "seed", has given rise to (at least two) widely different diseases, which now reproduce themselves as surely as "the fig comes from the fig, the grape from the grape, or the thorn from the thorn". (Professor Tyndall on "Dust and Disease").

1. *Well-defined diseases present many prominent and important changes in different epidemics.*—The truth of this statement is borne out by the experience of all observers of zymotic diseases. Epidemics of scarlatina are at one time largely fatal, at others scarcely so at all. Some epidemics are accompanied with prominent throat-symptoms, from which others are almost free. Epidemics of measles are sometimes observed in which catarrhal symptoms play no part; while in others they are the most pronounced and lethal symptoms. Sir Thos. Watson says: "I am firmly persuaded, by my own observation and by the records of medicine, that there are waves of time through which the sthenic and as sthenic characters of disease prevail in succession, and that we are at present living amid one of its adynamic phases". (*Principles and Practice of Physic*, 4th edit., note, p. 234.)

2. *New diseases appear during epidemics from time to time, which ever after assume a persistent type.*—The origin of cerebro-spinal meningitis may serve as an example of the truth of this statement. This disease was not recognised till late on in this century. It sprang into existence during an epidemic of typhus, from which it now differs as distinctly as typhoid, and, so far as experience has gone to prove, it now always 'breeds true'; i.e., reproduces itself, never showing any tendency to reversion towards the parent stock. Again, there is strong evidence to show that so well defined and easily described a disease as small-pox did not exist prior to the seventh century: there is no mention of it earlier than this, Paulus Ægineta amongst others not alluding to it (J. F. Marson). At the same time, it must be remembered that diseases which can only have been rarely witnessed, such as hydrophobia, were very minutely and accurately described many centuries before this period. The first recorded outbreak of yellow fever does not date further back than 1647. How far the comparatively recent origin of scarlatina, diphtheria, or syphilis, might be proved, I have no space to more than hint at.

3. *The same transmitted disease sometimes differs in its manifestations in parent and in child.*—From the numerous illustrative diseases which might be adduced to support the truth of this statement, I select syphilis. Inherited syphilis differs from acquired syphilis in the occasional presence of certain lesions which are never met with in the acquired form of disease; of this, interstitial keratitis is an example. It also differs in the coexistence of secondary and tertiary symptoms—the tertiary symptoms sometimes even preceding the secondary, as in congenital syphilitic albuminuria. Let me add one more illustration in support of this proposition. A parent dies from tubercular phthisis, leaving three children; of these, one dies during his second year from arachnitis, another at the age of fifteen from caries of the spine, the

third at twenty from peritonitis. Granted that in each of these cases we have a pathological product called tubercle, which we can thoroughly examine, and, examining, find it to be the same in all four cases; is it not, to say the least of it, highly probable that if we are ever able to examine the "seeds" of the different zymotic diseases, we shall find them exactly alike; i.e., so far as our senses enable us to judge? At the same time it will be admitted that in nearly all its features arachnitis differs as widely from peritonitis as small-pox does from typhus.

4. *Zymotic diseases are correlated.* By way of illustration, I will first mention the correlation observed between remittent and intermittent fever. "A remittent fever," says Dr. Maclean, "may, after a time, pass into one or other types of an intermittent, and conversely, an intermittent may assume the graver form of a remittent, either under the influence of a fresh charge of malaria, or, as I have frequently observed, under the stimulus merely of exposure to a higher temperature" (W. C. Maclean, M. D., in *Reynolds's System of Medicine*, p. 609). The next illustration is an example of zymotic disease exhibiting a tendency towards reversion to a former type. Dr. Gavin Milroy writes thus, on the correlation of typhus to the plague, etc.: "That glandular swellings, and occasionally also carbuncles, may be present in other forms of pernicious fever, malarial or not, besides the plague, has been frequently noticed by writers of different countries. For example, the endemic fevers of the Danubian Principalities, which were so terribly destructive to the Russian armies in the campaign against the Turks in 1828-29, as on all former occasions, and which were sometimes called putrid typhus, and at other times pernicious intermittent, are described as being often accompanied with buboes, carbuncles, and purple blotches of the skin. In the earlier part of the year dysentery with ordinary intermittents and remittents, were very common and fatal, the latter insensibly lapsed into the pestoid fever. The worst cases were evidently undistinguishable from that of the plague." Sydney Ringer alludes to a correlation between measles and whooping-cough. "The one disease apparently predisposes to the other," and again, "it is stated that persons with pulmonary disease, such as bronchitis, are especially apt to catch the disease." Diphtheria is so closely correlated to croup, that the former is often spoken of as an epidemic form of the latter. Trouseau remarks, "In point of fact, we see many more who are attacked by this disease (diphtheria) die from croup than from malignant sore throat" (*Clin. Med.*, translated by New Sydenham Society, vol. iii, p. 475). It has often been noticed that relapsing fever prevails during epidemics of typhus, and that it is most marked during the decline of the latter disease.

5. *Diseases are sometimes artificially induced, which afterwards become hereditarily transmissible.*—The well known experiments of Brown-Séquard afford sufficient evidence of the truth of this proposition. He mechanically induced epilepsy in guinea-pigs, and afterwards bred from them. The disease had become hereditarily transmissible, the offspring proving epileptic.

6. *It can be demonstrated in one instance that the same poison-germ or seed has given rise to (at least) two widely different diseases, which now (as is generally believed) always reproduce themselves.*—The instance to which I refer is syphilis. The proof of my statement is as follows. The contrast between the two forms of syphilitic sore and their respective significance is as well and sharply drawn as anything in surgery. The one is a local lesion, the other a constitutional malady; the one leaves no trace behind, the other for years poisons the fluids, infiltrates the viscera, and evolves from itself a long list of diseases, which become hereditarily transmissible—such diseases, e.g., as scrofula (Diday, etc.), phthisis, albuminuria, epilepsy, paralysis, etc. In the hands of numerous experimenters, the non-infecting chancre has proved auto-inoculable. The inoculability of the infecting sore also now rests upon an equally irremovable foundation. But what evidence is there as to their ever interchanging? At the annual meeting at Plymouth this year, I hope to be enabled to demonstrate the fact that the soft sore is sometimes directly produced from the hard infecting sore, and this in a system previously unsyphilitised. For some time, syphilographers (even including the great dualist, Ricord) have admitted that in syphilitised individuals the soft sore is sometimes transmitted from the hard, but maintain that this is never done in an uncontaminated constitution. This I believe I shall be able to disprove. At present, I can only say that, after numerous inoculations with scrapings from hard chancres, I at length succeeded in producing a soft chancre in the ear of a kitten, while I had syphilitised her sister with virus from the self-same sore. If space permitted, I would add much testimony on this point, but must content myself with saying that, without being in possession of such direct experimental evidence in favour of the original unity of the poison as the above, Mr. Savory argues powerfully in favour of the oneness of origin in last year's *Bartholomew's Hospital Reports*; and a similar belief is held by many other writers on the subject.

Superficially as I have, from necessity, treated each separate argument, I have perhaps said enough to show that there are arguments which speak strongly in favour of the doctrine of the evolution of disease. To many, indeed, I doubt not, it will occur, as it does to me, that if the principle of selection were not, for obvious reasons, carefully excluded, diseases might be bred with the same accuracy as that with which we breed a flower or a sheep; and that, if any peculiar symptom were required, it could be exalted into a persistent type, just as surely as the markings upon a Mrs. Pollock geranium have been by the selection of the horticulturalist.

### THE BRITISH MEDICAL ASSOCIATION.

SIR,—I have the honour to request publication of the accompanying correspondence. I am, etc.,  
SAMPSON GAMGEE.  
18 Broad Street, Birmingham, June 26th, 1871.

My dear Sir,—The more carefully I consider the notices of motion for the next Annual Meeting of the Association, published in your name in the *BRITISH MEDICAL JOURNAL*, the more deeply am I impressed with the sense of their great importance. The laws of the Association are, I believe, twenty-seven in number, and of these, no less than twelve are affected, several radically, by your notices of motion. I think our Associates might be assisted in forming a correct estimate of the changes you propose to effect, if you deemed it advisable to direct the publication, in an early number of the *JOURNAL*, of the laws as they are now in force, and as they would be if your notices of motion became law.

It appears that you propose that the Secretary shall no longer be a member of the Council or of the Committee of Council, but that such officer shall henceforward reside in London, and devote the whole of his time to the business management of the Association and of the *JOURNAL* office. Without venturing to express any opinion on the advisability of effecting such a change, I submit that it is not merely an administrative alteration, but deeply affecting the fundamental principles on which the Association was founded.

When it was deemed advisable to change the name of our body from the Provincial to the British Medical Association, it was generally felt to be in the interest of the profession to maintain the independence of the Association, from those metropolitan influences which have hitherto centred so powerfully in the medical corporations, and have militated in favour of the few, against the general interest of the great body of practitioners throughout the country. The events of late years have not detracted from the cogency of arguments, formerly held to be valid, in favour of an independent organisation of the profession.

It has been stated that, as at present administered, the British Medical Association has become practically a great joint-stock enterprise for the publication of a weekly journal, which absorbs nearly the whole of the Association's income. Hitherto, the independent action of the Secretary, a medical practitioner residing in the provinces, and having a seat on the Council and the Committee of Council, has secured to the great body of practitioners an official representative not under the control of the *JOURNAL*; but if the Secretary is to be reduced practically to the position of a paid clerk residing in London, and charged with the business management of the *JOURNAL* office, as well as of the Association, he must be subordinate to the Editor, or, in business matters, be co-ordinate with him in authority; the latter alternative would be incompatible with good government, while the former would inevitably lead to such a centralisation of power in the Editor of the *JOURNAL* as to render him practically, for the time being, the Master of the Association.

I do not observe that you contemplate making any alteration in Law 23, concerning the audit of accounts. Hitherto it has been held, though by no means unanimously, that the independent position of the Secretary and the Editor acted to some extent as a check in the financial arrangements. If, however, you propose to make the Secretary a clerk in great part subordinate to the Editor of the *JOURNAL*, an official public auditor of the accounts could scarcely fail to give very general satisfaction, the more so, since no official denial has been given to the rumour, current on very good authority, that the funds of the Association have lately suffered materially from the action—which I do not attempt to characterise—of one of its subordinate servants.

The British Medical Association has adopted a policy with the avowed intention of influencing the Legislature in the reform of the Medical Acts. Five of our most distinguished Associates, amongst the leaders of the medical profession in the three Kingdoms, have recently resigned all connection with the Association on a question vitally affecting its management. Is it too much to presume that you have taken those facts into full consideration with your colleagues on the Committee of Council, before giving the notices of motion to which I refer? If this assumption be correct, is it not reasonable to look to you for a statement of the reasons which have led you, at so critical a period in its history, to propose such extensive organic changes in the management of the Association?

Since your proposals open up the whole question of the government of our body, it is essential that full opportunity be given for discussion; and I suggest that you give notice of a special meeting during the approaching Annual Meeting, for the discussion of your notices of motion. I intend forwarding copies of this communication to the medical journals, but shall not do so before the 27th instant, so that I may transmit with it a copy of any reply with which you may favour me.

I am, dear Sir, faithfully yours,  
SAMPSON GAMGEE.  
William D. Husband, Esq., F.R.C.S., J.P., President of the Council of the British Medical Association.

16, Bootham, York, June 26th, 1871.

My dear Sir,—The most important alterations in the laws, of which I have, at the request of the Committee of Council, given notice in the *JOURNAL*, will only be proposed at Plymouth, if the members agree to the proposal which will be submitted to them to propose the business working of the Association and *JOURNAL* office.

The Committee of Council will fully submit to the Council, and, if the Council approve, to the meeting, the reasons which have induced it to recommend the proposed changes in the working of the Association. These changes can in no way lead, as you fear, to metropolitan or editorial supremacy, as the election of the governing body by the members generally so vast a proportion of whom reside in the provinces will not be affected.

The meeting must decide when the discussion on the report of the Council shall be taken.

I had, before receiving your note, taken steps to have the proposed alterations in the laws printed in the *JOURNAL*, in a form which will render them more intelligible to the members.—I am, yours very truly,  
W. D. HUSBAND.  
Sampson Gamgee, F.R.S. (Edin.)

18, Broad Street, Birmingham, June 26th, 1871.

My dear Sir,—I lose no time in thanking you for your prompt and kindly courteous acknowledgment of mine of the 24th inst. I regret that I cannot attach the importance which I generally do to your opinions—to the statement that the changes you propose "can in no way lead to metropolitan or editorial supremacy, as the election of the governing body by the members generally (so vast a proportion of whom reside in the provinces) will not be affected." The government of the Association, professedly based on representative principles, has, so far as I am informed, no parallel in any representative assembly or society in the world. The nominally supreme Council has no control over the constitution, as a distinguished Associate once cogently put it, during a recess of three hundred and sixty-one days in the year. Whatever be the theory of our constitution—a most legitimate matter for difference of opinion—the practical effect is scarcely open to question. Take, for instance, the ensuing year, hopefully looked forward to by medical reformers; who will wield the power of the Association when its President resides in Plymouth, the President of the Council at York, the Treasurer at Bath, and the members of the Council will be scattered in units over the three kingdoms? While 37, Great Queen Street, or some such central office in the metropolis, will be the head quarters of the editor and of his subordinate officer, who will combine the functions of business manager of the *JOURNAL*, and of Secretary of the Association. A fact not to be forgotten is, that no provision is made in the laws, or in your notices of motion, either for a public audit, or for substantial security being given by paid servants who may have the handling of the whole income of the Association.

I am happy to think that this discussion is not with yourself personally, for whom I have always entertained most sincere respect. You have confirmed my anticipations that the notices of motion of the most important alterations of laws have been given at the request of the Committee of Council, and I therefore hold myself at liberty to promote, or take part in, such measures as may be deemed necessary for bringing to an issue, on public grounds, questions which, however solved, cannot fail to exercise an important influence on the future of the Association, and on the best interests of the medical profession. According to previous intimation, I forward copy of our correspondence to all the medical journals.—I remain, very faithfully yours,  
William D. Husband, Esq., etc.

SAMPSON GAMGEE.

\* \* \* One at least of "all the journals" to which Mr. Gamgee sends this correspondence will, no doubt, be duly grateful to him. We cannot but think, however, that his zeal for other medical journalistic interests which he represents locally has in this instance caused him to forget the considerations which would ordinarily prevent a member seeking the true interests of the Association from looking for sympathisers in his attack outside the pale of his fellow-members, and addressing it to those who will read it without having the opportunity of reading the answer. Without discussing this hostile proceeding, we feel called upon to observe that the letter swarms with mischievous fallacies. To one, of which he makes himself the echo, we ought perhaps to reply. The British Medical Association has not now "become practically a great joint-stock enterprise for the publication of a weekly journal" in any sense other than it has been ever since the Association, many years since, found it possible and desirable to secure for its members fifty-two weekly journals instead of one annual publication. The weekly publication has become of late years more and more powerful as an organ of medical opinion, and by the larger amount of advertisements which it has attracted it has been found possible to give the associates a progressively larger return for the same subscription, and, without raising that subscription, to supply them with a journal which, with the great majority, supersedes the necessity of their subscribing an additional twenty-five or thirty shillings a year to some other journal also. The real grievance of Mr. Gamgee's journalistic clients is not that the Association has a journal, but that, with an annual subscription so low, it is now able to secure to itself an organisation which is more extensive, more powerful in the state, more thoroughly localised, more influential in the profession, and more representative than ever it was, and at the same time to supply its members with a weekly journal, which an honourable London contemporary has candidly described as equal to any, and which also published foreign judgment—in which, it is said, one hears the voice of posterity—has pronounced to be at the head of British journalism. If this *JOURNAL* were less complete, that which Mr. Gamgee represents would have less to say against the Association. If it collected no news, so that the associates had to look elsewhere for current intelligence; if it omitted to report the proceedings of the societies of London, Edinburgh, and Dublin; if its interest could be destroyed; or if it could be reduced to its former dimensions, and thus the members of the Association could be compelled to subscribe to another journal also, nothing would remain to be said. If the Association were reduced to its original position of holding an annual meeting and publishing a volume of *Transactions*, it would then be as opprobrious to describe it as practically a joint-stock company for publishing *Transactions*, as it would be to describe the Clinical, Pathological, or Obstetrical Societies in similar language; but, as for the same subscription it is now practically able, by securing an advertisement fund, to issue fifty-two weekly serial papers, and to ensure constant communication between all its members throughout the year on all professional, political, scientific, and social questions, the writers of whom Mr. Gamgee has become spokesman choose to ignore the Medical Reform Committee of the Association, its State Medicine Committee, its Parliamentary Committee, its Poor-law Committee, its ubiquitous local scientific and social gatherings, its great annual meetings, its power, prosperity, and growth. They choose to conceal, under a plausible cry, their real grievance that the members of the Association do now secure for themselves, at the cost of about sixteen shillings, what private proprietors wish to sell them at about double the price; and that they make this economy the means also, and the servant, of a great power—the power of unity, of professional concord, and of common co-operation in the working out of the ends of a great and united profession. If the Association goes on in the next few years as it has in the past few years, it threatens to spread over every corner of the land; to unite the whole profession in one bond; and to speak, through its *JOURNAL*, its Branches, its Committees, and its annual meetings, with a voice which will be irresistible. To some of Mr. Gamgee's friends this prospect is very alarming; but we doubt whether he is altogether wise to make himself their spokesman. As to the business matters which Mr. Gamgee discusses, we have only to observe that the duties of the Secretary are wholly distinct from those of the Editor, whom the place of residence of that officer cannot in any way concern; that the proposed changes emanate entirely from the provincial members of Council, aim solely at securing a more effective scheme and economical conduct of the business and financial matters of the Association, and in no way alter or affect the duties and relations of the Editor.

## ASSOCIATION INTELLIGENCE.

### BRITISH MEDICAL ASSOCIATION: ANNUAL MEETING.

THE Thirty-ninth Annual Meeting of the British Medical Association will be held in Plymouth, on Tuesday, Wednesday, Thursday, and Friday, the 8th, 9th, 10th, and 11th of August next.

*President*—E. CHARLTON, M.D., D.C.L., Physician to the New-castle-upon-Tyne Infirmary.

*President-elect*—JOHN WHIPPLE, Esq., F.R.C.S., Consulting Surgeon to the South Devon and East Cornwall Hospital.

An *Address in Medicine* will be delivered by GEORGE JOHNSON, M.D., F.R.C.P., Professor of Medicine in King's College, London.

An *Address in Surgery* will be delivered by JOSEPH LISTER, Esq., F.R.S., Professor of Clinical Surgery in the University of Edinburgh.

*Notices of Motion*.—The following notices have been given.

The PRESIDENT OF THE COUNCIL: Rule 4. To insert "President-elect", and to omit "Secretary".—Rule 6. To expunge this rule, and to substitute the following: "Each retiring President of the Association and President of Council shall be appointed a Vice-President for life by a vote of the members at the Annual Meeting."—Rule 7. To add "the Vice-Presidents" after President-elect; to insert the word "and" between President of the Council and Treasurer, and to erase "and the Secretary".—Rule 8. In this and every rule where "District" is prefixed to Branch, to erase the word "District", and to erase the words "the Secretary of the Association".—Rule 9. To omit the words between "The President of the Council" and "shall be elected".—Rule 10. To omit the words between "The Treasurer" and "shall be elected".—Rule 11. To erase the words after "There shall be one paid Secretary" in first section, and to substitute "who shall reside in London, and devote his whole time to the business management of the Association and of the JOURNAL office". To erase the words "otherwise" in seventh line and "an annual or special" in eighth line, and to insert "each Annual Meeting".—Rule 13. To erase the words "Secretary shall call", and to substitute "President of Council shall direct to be called".—Rule 14. Between "shall" and "be recommended", to insert "express his desire in writing, and shall be".—Rule 15. To add "Members may be admitted on and after July 1st in each year, and the subscription for such part of a year shall be half a guinea". To erase the words after "each member" in eighth line, and to substitute "as long as his subscriptions remain unpaid, provided due notice shall have been given of such withholding".—Rule 16. To erase the words after "from his" in fourth line, and to substitute "liabilities to the Association".—Rule 24. In tenth line, to insert "a copy of the laws" between "Association" and "and".

Dr. STEELE (Liverpool): Election of Committee of Council. Every associate, who is a member of the Council, and desirous of a seat on the Committee of Council, shall send to the General Secretary, not later than months prior to the Annual Meeting of the Association, a declaration signed by himself, and in the following terms: "I, A. B., of C., member of the British Medical Association, hereby declare that I am a candidate for a seat on the Committee of Council of the said Association. (Signed) ———." Together with a nomination-paper signed by six members of the Association, in the following terms: "We, the undersigned, members of the British Medical Association, certify that A. B., of C., is a fit and proper person to be a member of the Committee of Council of the said Association." The names of the eligible candidates, with the names of the six associates by whom they shall have been respectively nominated, shall be published in the BRITISH MEDICAL JOURNAL not later than months prior to the Annual Meeting of the Association.

Mr. NICHOLSON (Hull): To alter Law 16, line 2. For "three", insert "two".

Dr. WADE (Birmingham): In Law 8, Paragraph No. 3, of the duties of Council, to alter "ten" into "twenty-five"; and to omit the words "and one Secretary from each Branch".

Gentlemen desirous of reading papers, cases, or any other communications, are requested to give notice of the same to the General Secretary at their earliest convenience.

T. WATKIN WILLIAMS, F.R.C.S., *General Secretary*.

13, Newhall Street, Birmingham, June 13th, 1871.

### NORTH WALES BRANCH.

THE twenty-second annual meeting of the above Branch will be held at the Castle Hotel, Ruthin, on Tuesday, July 4th, at 12 o'clock; J. R. JENKINS, M.D., *President*.

The dinner will take place about 4 P.M., at the usual charge.

Gentlemen having papers or cases to communicate, and who intend dining, will much oblige by sending *early* intimation to the Secretary.

D. KENT JONES, *Honorary Secretary*.

Beaumaris, June 14th, 1871.

### WEST SOMERSET BRANCH.

THE annual meeting of the above Branch will be held at the Royal Clarence Hotel, Bridgewater, on Tuesday, July 4th, at 2 P.M.; J. CORNWALL, Esq., Ashcott, retiring President; W. H. AXFORD, M.B., Bridgewater, *President-elect*.

The dinner-hour is fixed at half-past five o'clock. Tickets 5s. each, exclusive of wine and waiters.

Gentlemen intending to be present, or wishing to read papers, are requested to inform the Secretary on or before the 30th instant.

W. M. KELLY, M.D., *Honorary Secretary*.

Taunton, June 14th, 1871.

### SOUTH WALES AND MONMOUTHSHIRE BRANCH.

THE first annual meeting of the above Branch will be held on July 5th, at the Swansea Hospital, at 1.30 P.M.: *President*, GEORGE PADLEY, L.R.C.P. Lond.

Dinner will be provided at the Mackworth Hotel at 5 P.M. Tickets, 6s. 6d. each.

Members desirous of reading papers or notes of cases, are requested to communicate the titles at as early a date as possible to one of the undersigned.

A modification of Rule No. 2 of the Branch will be proposed at the meeting.

The Council will meet at 12.30 P.M.

Members of the Branch may introduce members of the profession to the annual meeting and dinner.

All members intending to join the latter, will oblige by sending to one of the Honorary Secretaries a communication to that effect on or before the 30th inst., so that arrangements may be made and tickets reserved.

A. DAVIES.

A. SHEEN, M.D. } *Honorary Secretaries*.

June 14th, 1871.

### BATH AND BRISTOL BRANCH.

THE annual meeting of the above Branch will be held on Thursday, July 13th, 1871, at the Institution at the top of Park Street, Bristol, at 4.45 P.M., when C. BLEECK, Esq., will resign the Chair to CROSBY LEONARD, Esq., *President-elect*, who will deliver an address.

Members having any communications for the meeting are requested to give notice of them to the Secretaries.

Members who have not paid their subscriptions, are requested to do so to the Local Secretaries at or before the annual meeting, in order that the accounts may be made up before the anniversary meeting of the Association.

The dinner will be held at the Royal Hotel, College Green, Bristol, at 6.30 P.M. Dinner tickets, including ice and dessert, 7s. 6d. each. Wines at moderate charges.

It would help the arrangements at the Bristol annual meeting, if those gentlemen who intend to be present at the annual meeting of the Association in Plymouth would kindly inform the Secretaries.

The Bristol Secretaries particularly requests that those members who intend to be present at the dinner, will send him their names before Monday, July 10th, in order that the necessary arrangements may be completed.

E. C. BOARD, Clifton. }

R. S. FOWLER, Bath. } *Honorary Secretaries*.

### CUMBERLAND AND WESTMORLAND BRANCH.

THE third annual meeting of the above Branch will be held at the Bush Hotel, Carlisle, on Wednesday, July 12th, at 1 o'clock. *President*, Dr. P'ANSON, Whitehaven; *President-elect*, Dr. ELLIOT, Carlisle.

Dinner will be provided at 4.30, at the usual charge.

Gentlemen having papers or cases to communicate, will greatly oblige by sending early intimation to

HENRY BARNES, M.D., *Honorary Secretary*.

Carlisle, June 20th, 1871.

## METROPOLITAN COUNTIES BRANCH.

THE nineteenth annual meeting of this Branch will be held at the Castle Hotel, Windsor, on Friday, July 14th, at 3 P.M. *President for 1870-71, T. HECKSTALL SMITH, Esq., F.R.C.S.; President-elect for 1871-72, J. RUSSELL REYNOLDS, M.D., F.R.S.*

Dinner at the Hotel at 5.30 P.M.

A. P. STEWART, M.D.

ALEXANDER HENRY, M.D.

Honorary Secretaries.

75, Grosvenor Street, June 13th, 1871.

## THE PROPOSED ALTERATIONS IN THE LAWS.

As many members of the Association may not have ready at hand the means of understanding the modifications proposed to be introduced into the Laws of the Association, we subjoin a copy of those laws which it is intended to alter, together with the alterations which will be submitted to the annual meeting. The words enclosed within brackets, in the ordinary Roman type, are to be omitted; the bracketed words in italics are to be inserted. In all cases, except where otherwise specified, the alterations are brought forward by the President of Council, at the request of the Committee of Council.

4. *Council and Officers.*—The Association shall be governed by a Council. The officers of the Association shall be—1. A President; [2. A President-elect]; 2. Vice-Presidents; 3. President of the Council; 4. Treasurer; [5. Secretary.]

6. *Vice-Presidents.*—[The Vice-Presidents of the Association, who have been appointed after fulfilling the office of President, shall continue to enjoy the office for life; and the office of Vice-President shall be hereafter conferred, as an honorary distinction for life, on the retiring President, by a vote of the members at the Annual Meeting.] [*Each retiring President of the Association and President of Council shall be appointed a Vice-President for life by a vote of the members at the Annual Meeting.*]

7. *Council.*—The Council shall consist of the President, the President-elect, the President of Council, [*the Vice-Presidents, and*] the Treasurer [*and the Secretary of the Association*], together with those members who shall be elected annually, according to Law 8. Its meetings shall be held at the time and place of the Annual Meeting, and at other times and places, if summoned by the President of the Council, or by the Committee of Council, or by a requisition signed by twenty members of Council.

8. *Election and Duties of Council.\**—Each [District] Branch shall, in such manner as they think fit, before the General Annual Meeting, elect members who shall represent the Branch in the Council for the ensuing year, according to the following scheme. In a Branch consisting of not less than twenty members, one member shall be elected as representative, in addition to the Honorary Secretary. If the members amount to more than twenty, for every number of twenty additional members, each Branch shall be entitled to choose one additional representative. A complete list of the Members thus chosen shall be sent to the Secretary at least a fortnight before the Annual Meeting, and they shall continue in office till the close of the official year, when they may be either reappointed or superseded. The duties of the Council shall be—1. To agree upon a Report to be presented to the Annual General Meeting of the Association. 2. To nominate a President, to be submitted for election to the Annual Meeting. 3. To elect by voting papers [ten] [*twenty-five*]† members of the Council, who, together with the President of the Association for the year, the Vice-Presidents, the President-elect, the President of Council, the Treasurer, [*the Secretary of the Association*], [*and one Secretary from each Branch*]‡ shall constitute the Committee of Council for the ensuing year. 4. To propose the place of meeting of the Association for the ensuing year. 5. To nominate gentlemen to read such addresses as may be deemed expedient at the Annual Meeting of the ensuing year. 6. To determine the order of business of the General Meeting, so far as that is not determined by the laws relating to General Meetings.

9. *President of the Council.*—The President of the Council [shall be, in the first instance, Sir Charles Hastings, permanently; and on any vacancy occurring, the President] shall be elected by the Council, at the Annual Meeting, for a term of three years.

10. *Treasurer.*—The Treasurer [shall be, in the first instance, Sir

Charles Hastings, permanently; and on any vacancy occurring, the Treasurer] shall be elected at a General Meeting of the Association; and shall hold his office during pleasure.

11. *Secretary.*—There shall be one paid Secretary [resident in some convenient locality, so as to communicate readily with the President of the Council and the Committee of Council] [*who shall reside in London, and devote his whole time to the business management of the Association and the Journal office*]. His duties shall be to be present at the meetings of the Association, of the Council, and of the Committee of Council; to record their minutes; to conduct the correspondence of the Association; to superintend the collection of subscriptions, and the enforcement of the laws as regards those in arrear; and [otherwise] to obey the directions of the Council and the Committee of Council. The Secretary shall be elected at [an Annual or Special] [*each Annual*] Meeting of the Association. The offices of Secretary and Editor of the JOURNAL shall not be held by the same person.

12. *Committee of Council.*—The Committee of Council shall manage the affairs of the Association in the intervals between the General Meetings; they shall meet not less than twice in the year, and shall be presided over by the President of the Council; or, in his absence, by a Chairman appointed by the meeting. The Committee of Council shall appoint the Editor of the JOURNAL, who shall be responsible to them for its management: they shall direct any other publications of the Association, and shall take cognisance of any matter which may require immediate decision. Five members to be a quorum. [The Secretary shall call a meeting of the Committee] [*The President of Council shall direct a meeting of the Committee to be called*] at any time on receiving a requisition from five of its members, the object for which the meeting is called being specified.

14. *Admission of Members.*—Any qualified medical practitioner, not disqualified by any bye-law, who shall [*express his desire in writing and shall*] be recommended as eligible by any [three] [*two*]\* members, shall be admitted a member at any time by the Committee of Council, or by the Council of any Branch; provided he shall have the votes of three-fourths of those present.

15. *Subscription.*—The Subscription to the Association shall be One Guinea annually; and each member, on paying his subscription, shall be entitled to receive the publications of the Association for the current year. The subscription shall date from the 1st January in each year, and shall be considered as due unless notice of withdrawal be given in writing to the Secretary, on or before the 1st of December previous. If any member's subscription remain unpaid twelve months after it shall have become due, the publications of the Society shall be withheld from such member [until his arrears be paid] [*so long as his subscription remains unpaid, provided due notice shall have been given of such withholding. Members may be admitted on and after July 1st in each year; and the subscription for such part of a year shall be half a guinea*].

16. The name of no member shall remain on the books of the Association, whose arrears extend over three years; but the omission of the name from the list of members shall not be deemed, either in honour or equity, to relieve any member from his [liability for the subscriptions due for the period during which he has availed himself of the privileges of membership] [*liabilities to the Association*].

24. *Publications.*—The JOURNAL, under the title of the "BRITISH MEDICAL JOURNAL: BEING THE JOURNAL OF THE BRITISH MEDICAL ASSOCIATION," shall be published weekly in London, and shall be conducted by a paid Editor, who shall be responsible for all that appears in its pages, except such matter as may be printed by direction of the Council or Committee of Council. The JOURNAL shall contain papers on medical science, and shall be considered the medium of communication between the members of the Association. In it shall be inserted all intimations of places and times of meetings, whether of the Association or the Branches; notices of motions, etc.; at least once in each year a list of the members of the Association [*and a copy of the Laws*]; and any other Association business that the Council or Committee of Council may direct. Transactions shall be published occasionally, if the funds of the Association permit.

## COMMITTEE ON PARLIAMENTARY BILLS.

A MEETING of the Parliamentary Bills Committee of the British Medical Association was held on Wednesday, June 28th, at 37, Soho Square: Present, Mr. Michael, in the Chair; Mr. Lord, Dr. Stewart, Dr. Henry, Dr. Davey (Bristol), Mr. Ernest Hart, Mr. Benson Baker.

The Vaccination Act Amendment Bill, the Pharmacy Act Amend-

\* The alterations proposed by the Council (see preceding page) must be read in connection with this Law.

† Dr. Wade.

‡ The omission of the words "and one Secretary from each Branch," is proposed by Dr. Wade.

\* Mr. Nicholson.

ment Bill, and the Registration of Births Amendment Bill, were considered. The following resolutions were unanimously passed.

It was moved by Dr. STEWART, and seconded by Mr. LORD—"That the purchase of immunity from the operation of the Act provided by Clause 10 of the Vaccination Amendment Bill, is vicious in principle, and that such clause should be expunged."

It was moved by Dr. STEWART, and seconded by Dr. DAVEY—"That, considering the expected action next year of the Government in reference to the recommendations of the Royal Sanitary Commission, and the anticipated adoption of a comprehensive plan of sanitary organisation for the whole kingdom, it is inexpedient to create a new class of health-officers with permanent claims, and that the appointment of vaccination officers should therefore be limited to one year from the commencement of the Act."

Regarding the Pharmacy Act Amendment Bill, Mr. LORD moved, and Mr. BENSON BAKER seconded—"That it is desirable that provision should be made for the due carrying out the regulations for keeping, dispensing, and selling of poisons, and that for this purpose a clause should be introduced providing inspectors to ascertain that they are carried out."

The Registration of Births Amendment Bill was considered and approved; but it was stated that it would be opposed this year on the ground that it was piecemeal legislation, and that a larger measure, including it was under consideration, and expected to pass next year.

The Secretaries were directed to forward copies of the above resolutions to the Lord President of the Privy Council.

#### BIRMINGHAM AND MIDLAND COUNTIES BRANCH : ANNUAL MEETING.

THE seventeenth annual meeting was held at the Great Western Hotel, Birmingham, on Friday, June 16th, at 3 P.M.; OLIVER PEMBERTON, Esq., President of the Branch, in the Chair. Seventy-eight members and visitors were also present. Dr. Thomas Underhill, in resigning the chair to his successor, Mr. Pemberton, thanked the members for their courtesy during his year of office.

*Vote of thanks.*—A cordial vote of thanks was passed to Dr. Underhill for the ability, energy, and courtesy with which he had discharged his duties of President of the Branch during the past year.

*Report of Council.*—Mr. T. H. BARTLEET, Honorary Secretary, read the report of the Council of the Branch. "The position of the Birmingham and Midland Counties Branch of the British Medical Association again justifies your Council in congratulating its members on its continued progress and success. The Branch now contains 252 members. During the past year, forty new members have been elected; thirty-one have either resigned, left the neighbourhood, or been erased for non-payment of subscriptions, and four have been removed by death. Of these, Mr. Chesterman of Banbury, and Mr. Coleman of Wolverhampton, were old and respected members of this Branch, the latter having for many years been a member of its Council. Mr. Llewellyn Summers and Dr. Lumley Earle were recent members, and their early death is deeply regretted. During the past year, six general meetings and one special meeting of the Branch have been held; and at no previous period has more interest in the proceedings and more good feeling among the members been displayed. The list of papers, etc., shows the work of the session; but a categorical statement in no degree describes the scientific value of the papers, or the vigour of the discussions which followed their reading. [The report here contained a list of the papers read.] The pathological and clinical section has continued its important work. It is a great help to the Branch meetings, at which time often failed for the exhibition and discussion of pathological specimens and living cases. It has moreover, gathered to itself a *clientèle* of active and enthusiastic workers in pathology and clinical medicine and surgery.

"Your Council warmly acknowledges that this success is in no small degree due to the energy of the Chairman and Secretaries of the section.

"Your Council suggests that, should its resources permit, some portion of the funds of the British Medical Association should annually be set aside for the encouragement of original research in medicine, surgery, and the allied sciences; and it desires earnestly to represent to the Council of the Association the eminent claims of one of our Branch members, Dr. Richard Norris, to such a recognition of his labours. The able original work of Dr. Norris in the investigation of the Physiology of the Blood is well known to the scientific world, and to this Society in particular, by the elaborate and interesting experimental demonstrations which he has more than once given at our Branch meetings.

"Your Council desires to allude to the invitation sent by this Branch—called together at a special meeting—to the British Medical Association to hold in Birmingham its annual meeting in the year 1872. The

Committee of Council of the Association has expressed its approval and gratification, and there is every probability that the invitation will be accepted by the Association at its annual meeting at Plymouth in August next. In order to make the annual meeting, should it be held in Birmingham, thoroughly successful, the cordial help and support of all the members of the Branch will be essential. And your Council, whilst confidently relying upon this, assures the members of the Branch that no efforts on its part and on the part of the officers of the Branch will be spared to lead the meeting to an eminently successful and satisfactory ending.

"Your Council desires to impress upon the members the necessity of increasing the members of the Branch and of the Parent Association. To aid this, special lists have been prepared of qualified medical practitioners residing in this and the neighbouring counties, who do not as yet belong to the Association; and to these, to the number of five hundred, a special address, signed by the President, the President-elect, and the Honorary Secretary of the Branch, has been forwarded, and with it our list of members, an invitation to our annual meeting, and a form of proposal for membership. In the early part of the session, nearly a hundred special circulars were sent to members of the Parent Association who were living in the district, and who were not members of our Branch. By these means the advantages of our Association and Branch will have been widely disseminated; but your Council feels that much more success is likely to follow the personal representation by its members of these advantages to such professional friends as they can influence, who as yet do not belong to the Association. Such influence your Council urges its members to exert, until hardly a member of the profession in this great district is to be found outside our ranks.

"Your Council desires to report that it has carried out, to the best of its ability, the wishes of the Branch in regard to the election of its Council and officers.

"In conclusion, your Council has every reason to anticipate in the coming year a session of activity, energy, and interest, in no way less than that displayed in former years."

The Treasurer, Mr. T. WATKIN WILLIAMS, read his report, which showed a balance in hand of £12 : 7.

The reports of the Council and of the Treasurer were received, adopted, and ordered to be entered upon the Minutes.

*Officers and Council.*—Dr. FOSTER read the report of the Scrutineers appointed to examine the voting papers for the election of the officers and Council of the Branch. *President-elect:* Thomas Ebbage, Esq., Leamington. *Treasurer:* T. Watkin Williams, Esq. *Secretary:* T. H. Bartleet, M.B. *Country Members of Council:* F. I. Bennett, L.R.C.P.Ed., Droitwich; G. Fowler Bodington, M.D., Sutton Coldfield; W. C. Garman, Esq., Wednesbury; A. J. Harrison, M.B., Walsall; J. H. Houghton, Esq., Dudley; Vincent Jackson, Esq., Wolverhampton; E. Malins, M.D., Cradley; J. Manley, Esq., West Bromwich. *Town Members of Council:* M. H. Clayton, Esq.; A. Fleming, M.D.; B. W. Foster, M.D.; T. P. Heslop, M.D.; J. Hickinbotham, L.R.C.P.Ed.; Furneaux Jordan, Esq.; A. Oakes, Esq.; James Russell, M.D.

*Representatives of the Branch in the Council of the Association:* Alfred Baker, Esq.; M. H. Clayton, Esq.; A. Fleming, M.D.; B. W. Foster, M.D.; J. S. Gamgee, Esq.; J. Manley, Esq.; C. A. Newnham, Esq. (Wolverhampton); Oliver Pemberton, Esq.; J. Russell, M.D.; J. Vose Solomon, Esq.; F. Turton, Esq. (Wolverhampton); Thomas Underhill, Esq. (Great Bridge); T. H. Bartleet, Esq., *ex-officio*.

*Votes of Thanks.*—The cordial thanks of the meeting were tendered to Dr. Foster and Mr. Manley, the Scrutineers appointed by the Council; also to Mr. Alfred Baker, the Chairman, Dr. Foster and Mr. Vincent Jackson, the Honorary Secretaries, and Mr. Furneaux Jordan, the Treasurer, of the Pathological and Clinical Section. Votes of thanks were also passed to the retiring Council, to the Representatives of the Branch in the General Council of the Association, to the Treasurer, Mr. T. W. Williams, and to the Honorary Secretary, Mr. T. H. Bartleet.

*President's Address.*—Mr. OLIVER PEMBERTON, the President, then delivered an able and interesting address, in which he referred to the rise and progress of this Branch, which from fifty members in 1855 had increased to two hundred and fifty, representing every branch of the profession in Warwick, Stafford, and Worcester. The gradual narrowing of the gulf which once existed between the physician and the general practitioner, the proper government of hospitals, and other topics, forced upon Mr. Pemberton in the daily working of his medical life, were touched upon in the address, the reading of which was well received.

On the motion of Mr. CARDEN, of Worcester, seconded by Mr. FURNEAUX JORDAN, the best thanks of the meeting were given to the President, Mr. Pemberton, for his courtesy in the chair, and also

for the interesting and able address, with a request that it might be published.

*Dinner.*—The members and visitors, to the number of fifty-four, afterwards dined together at the Great Western Hotel, Mr. Pemberton occupying the chair, and Mr. Ebbage the vice-chair.

## SPECIAL CORRESPONDENCE.

### BERLIN.

*The "Einzug" or Triumphal Entry.—The Small-pox Wards of the Charité Hospital.—Ergotine in Epistaxis.—Addison's Disease.—Defective Sanitary Conditions.*

THE "Einzug," or triumphal return of the troops to Berlin, although somewhat wanting in colour and effect, was a great and deserved success, but the intense heat must have made it a trying business for those more immediately employed. The men marched with wonderful steadiness, and with a spring and vivacity very creditable after a hard and hot walk of nearly six miles. I saw one poor fellow, however, go down as if shot, and have since learnt that twelve cases of sunstroke occurred during the day's proceedings, three of which have died, and the rest are not expected to recover. In addition to this, Prince Albrecht, brother of the Emperor, was seized with paralysis shortly after his return home, but is, I believe, in a fair way towards convalescence. Now, if these disastrous consequences happened to the Prussians, who are in first-rate war condition, and dressed with some regard to freedom of movement, how terrible would have been the mortality among an equal number of British troops. The uniforms of our men fit them with the exact precision of tailors' dummies; all variety of form is lost in tightness and padding, and if they look "smart" on parade, it matters little how useless they are in the field. As a consequence of this, they fall out by scores at the most ordinary drill, and, when occasion demands some more extraordinary exertion, we are horrified by the elaborate comments of our newspapers on the "fatal march" to this or that place. Now although, when we meet a soldier here, our first impression is that he wants the perfection of military bearing to which we are accustomed, closer inspection shows that the best material is there, unhampered by the paralysing influence of over-tight clothes. And, as I said before, after a long and exhausting walk, and being more than ten hours under arms, the men stepped along as though they had just left their barrack-rooms.

Another source of danger lay in the very slippery state of the streets. When the cavalry swung rapidly round out of the Linden to mass up in the open platz, horse after horse fell, and many others were seen skating about as though on ice. Not fewer than a hundred must thus have gone down in the course of the day; and although it would seem almost inevitable from the confused way in which man and beast struggled helplessly on the ground, that some bad accident must occur, every trooper, without exception, remounted and rode on to join his comrades; and I must say that the activity displayed under such trying circumstances, was among the most notable features of the affair.

A day or two ago, I paid a visit to that portion of the Charité Hospital devoted to the treatment of small-pox. It is a small detached out-house behind the main building, and about as little adapted for the accommodation of infectious disease as we can well imagine. Some of the rooms are mere garrets, and much over-crowded; and were it not for the enlightened views of Dr. Zuelzer, who keeps the windows open night and day, we might expect to hear of very bad results. As it was, however, the wards were perfectly sweet, much more so, in fact, than those of the main hospital, which are invariably "stuffy," and very often offensive from the smell of perspiration. The cases which I saw were mostly slight, but one very well marked instance of the so-called "scarlatinous small-pox" had been admitted that morning, exhibiting an eruption hardly to be distinguished from true scarlet fever. It was evidently a form of the hemorrhagic variety of the disease, as petechial spots were appearing on the skin, and both spots and urine consisted of almost pure blood. The treatment usually adopted consists of the wet sheet with cold affusion, and insufflation of alum for throat-complications: the ratio of success has hitherto been very favourable.

I see in your impression for June 3rd, a case by Mr. Jamieson, of hæmoptoe treated by subcutaneous injection of ergotine, as recommended by Dr. Balfour. It may, therefore, be interesting to mention that Professor Traube not long ago prescribed this application in very obstinate epistaxis, the result of secondary purpura after typhoid fever.

An interesting example of Addison's disease had lately occurred in the practice of Professor Frerichs. A woman was brought to his *clinique*, suffering from weakness, pain in the back, anemia, and loss of appetite; her only previous illness being intermittent fever, traces of

which still remained in some enlargement of the spleen. Observing a marked amount of uræmic pigmentation of the skin, especially about the angle of the mouth and forehead, the diagnosis was made accordingly, the Professor inclining to the theory which explains the progressive feebleness by an implication of the solar plexus. At the necropsy, which soon afterwards took place, both suprarenal capsules were found to be infiltrated with caseous deposit in a very marked degree, and the sympathetic nerves entering their substance were thickened.

The heat is now becoming very considerable, and the smells so bad that I am seriously considering whether it is safe to remain any longer here. At every turn, and even in the best neighbourhoods, we are met by the most sickening stenches; and, however these may affect the acclimatised inhabitants of the place, they must exert a lowering and depressing influence on strangers. A friend, who is staying here just now, has been quite knocked up by them, and matters are not mended by the very unsanitary water-closet arrangements prevailing in Berlin. If such things exist even in the more modern parts of the town, what must be the state of affairs in the dwellings of the poor? What power of resistance can they have against the ravages of epidemic disease?

Berlin, June 22nd.

## THE POOR-LAW MEDICAL SERVICE OF GREAT BRITAIN.

### VACCINATION IN THE LANCASTER UNION.

DR. BEARD, the Privy Council's Inspector of Vaccination, has been engaged several days in making a most careful investigation with regard to vaccination in the Lancaster Union. At a meeting of the Guardians, he expressed his satisfaction with the careful manner in which the law had been carried out by them. The following statement by the Clerk clearly exemplifies the success of their efforts to render the practice of vaccination universal in the Union.

During the two years ended June 30th, 1870, 2,120 children were born. Of these, 158, or 7.45 per cent., died before successful vaccination; 52, or 2.65 per cent., ceased to reside in the Union; 1,897, or 96.69 per cent., were, according to medical certificates, successfully vaccinated; and the remainder—only 13, or .66 per cent.—are still unvaccinated on account of unfitness, insusceptibility, etc. Deducting ten deaths and removals, the proportions per cent. are: successfully vaccinated, 99.32; unvaccinated, .68.

The result of the constant attention of the Guardians to vaccination has been most successful. The deaths from small-pox in Lancaster during the three years 1838, 1839, and 1840, were 54. The Guardians were charged in 1840 with the execution of the vaccination laws, and have strictly carried them out ever since; and there has not been a fatal case of small-pox in Lancaster since June 1862.

### VACANCIES.

GUISBOROUGH UNION, Yorkshire—Medical Officer for the Danby District.  
HOLSWORTHY UNION, Devon—Medical Officer and Public Vaccinator for the District No. 4.  
WIRRAL UNION, Cheshire—Medical Officer and Public Vaccinator for the Upton District.

## MEDICO-PARLIAMENTARY.

### HOUSE OF LORDS.—Monday, June 19th.

LUNACY REGULATION AMENDMENT BILL.—On the order for the third reading of this Bill, Lord Cairns said he looked upon it as a somewhat dangerous measure, for it introduced a new state of things into legislation with regard to lunacy, by declaring that persons of weak mind should come within its operation. That was a somewhat vague and indefinite term, and it might lead to very disagreeable, or even improper action. He hoped the noble and learned lord (the Lord Chancellor) who had charge of the bill would pause before he determined to carry it out.—The Lord Chancellor was surprised at the course taken by the noble and learned lord, who had never before given any intimation of the least objection to the bill. The bill was intended to remedy the defect in the existing law occasioned by the fact that people in a middle state of mind, who could not be said to be insane, but who yet were unable to manage their own property, and who could not give receipts, were not legislated for. The measure could not have any very dangerous effect, for property could only be dealt with for six months

under it, and he thought it was extremely desirable that such a measure should be passed.—The bill was then read a third time and passed.

HOUSE OF COMMONS.—Thursday, June 22nd.

THE VACCINATION ACT AMENDMENT BILL was read a second time.

## OBITUARY.

OLLIVE SIMS SHAW, M.R.C.S., OF STOCKPORT.

ANOTHER death has to be deplored in the person of this promising young surgeon, whose career has been prematurely cut short by typhus fever. Originally articled to a general practitioner at Stockport, and a pupil of the Infirmary of that town, Mr. Shaw finished his curriculum at Guy's Hospital; and, after being Assistant Medical Officer at the Gloucester Asylum, became House-Surgeon to the West Derby Union Hospital at Liverpool, where, overtaken by physical labour consequent on the severity of the present epidemic, he fell victim, after a few days' illness, to typhus fever—the disease which he was called upon to treat in others. Of amiable manners, frank and intelligent demeanour, untiring assiduity in his work, and strictly conscientious in his relations towards others, Mr. Shaw carried with him to the grave the affection and sympathy of all surrounding him.

ROBERT DAUN, M.D., EDINBURGH.

DR. ROBERT DAUN, Deputy Inspector of Hospitals, was born at Inch (Aberdeenshire) on the 16th of April, 1785, and was the eldest son of the clergyman of that parish. He received his early education at the Grammar school of Elgin, and pursued his medical studies at the University of Aberdeen. He passed his examination in London, and entered the royal army as assistant-surgeon at the early age of nineteen, almost his first service being in India, when he was attached to the 22nd Light Dragoons, and afterwards to the 59th Foot. On his return to England in the year 1814, he exchanged into the Scots Greys, and with them was present at the battle of Waterloo, and afterwards with the army of occupation in France. He went to India a second time about 1820, and served there for some years; returning finally to Europe in 1825. His great experience in the treatment of cholera caused his selection as government inspector, in which capacity he was sent to Sunderland and the other infected districts on the occurrence of the first great epidemic of the disease in 1831-32. For his services on this occasion he received the thanks of government and sundry other honorary distinctions. He was also frequently called into consultation on cases apparently hopeless, and in two instances at least succeeded in restoring the sufferer by the use of saline injections. He then retired into private life, from which he did not again emerge, residing successively in London, St. Andrew's, Aberdeen, and latterly in Edinburgh.

In private life his conduct and character were of the most amiable type; which, added to judicious benevolence, rendered his society most attractive to those who were fortunate enough to enjoy his intimacy. His reasoning powers were of a high order, his favourite pursuits being the higher mathematics and theology.

Dr. Daun was, at the time of his death, one of the Senior Fellows of the Royal College of Physicians in London, Fellow of the Royal Society of Edinburgh, and a member of various other learned societies.

## MEDICAL NEWS.

### THE GENERAL MEDICAL COUNCIL.

We believe that Dr. Gull has been nominated by the Crown as one of its representatives in the General Medical Council, in the room of Dr. Rumsey, resigned. Personally, the appointment will be viewed with favour; but we must express regret that a provincial member of the profession and one more intimately acquainted has not been chosen as the successor of Hastings and Rumsey.

### THE SESSION OF THE MEDICAL COUNCIL.

The General Medical Council of Registration and Education will commence its annual session on Tuesday next, at the Royal College of Physicians. The business on the paper includes little of importance beside the Report of the Committee of Council on Education. There are some names to be struck off the *Register*; one or two petitions for

restoration to the *Register*; communications from Sydney, as to the foundation of a School of Medicine; and other matters of minor importance.

UNIVERSITY OF CAMBRIDGE.—Second M.B. Examination, Easter Term, 1871. Examined and approved.

Hood, Caius  
Kilner, B.A., St. John's

Lees, B.A., Trinity  
Maxwell, B.A., King's

APOTHECARIES' HALL.—The following gentleman passed his examination in the science and practice of medicine, and received his certificate to practise, on Thursday, June 22nd, 1871.

Ellis, Edward Thomas Charles, Bexley Heath, Kent

As Assistants in compounding and dispensing medicines.

Dunn, Henry, Shipley, near Leeds  
Tomlin, Albert Roberts, Barnsley  
Williams, Jabez Vivian, St. Ives, Cornwall

### MEDICAL VACANCIES.

The following vacancies are announced:—

BOYLE UNION, co. Roscommon—Apothecary to the Workhouse.  
BROADMOOR CRIMINAL LUNATIC ASYLUM—Assistant Medical Officer.  
CUMBERLAND AND WESTMORLAND CONVALESCENT INSTITUTION, Silloth—Medical Attendant.

DUNDEE ROYAL INFIRMARY—Surgeon, West District.

DUNSHAUGHLIN UNION, co. Meath—Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the Killeen Dispensary District.

GATESHEAD DISPENSARY—Resident Medical Officer.

GENERAL LYING-IN HOSPITAL—Physician-Accoucheur.

GREAT YARMOUTH, Norfolk (Parish of)—Medical Officer for the North District.

HUDDERSFIELD AND UPPER AGBRIGG INFIRMARY—Physician.

INFIRMARY FOR CONSUMPTION AND DISEASES OF THE CHEST, Margaret Street, Cavendish Square—Visiting Physician.

KILKEEL UNION, co. Down—Medical Officer for the Workhouse and Fever Infirmary; Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the Kilkeel Dispensary District.

LANCASHIRE LUNATIC ASYLUM—Assistant Medical Officer.

LEEDS PUBLIC DISPENSARY—Junior Resident Medical Officer.

LIVERPOOL ROYAL INFIRMARY—Physician.

LURGAN UNION, co. Armagh—Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the Warrington Dispensary District.

METROPOLITAN FREE HOSPITAL, Devonshire Square—Assistant-Physician.

MIDDLESEX HOSPITAL—Physician; Assistant-Surgeon.

MIDDLESEX HOSPITAL MEDICAL COLLEGE—Lecturer on Physiology, including Practical Physiology.

RATHDOWN UNION, co. Dublin—Medical Officer for First Division of the Kingstown Dispensary District.

QUEEN'S COLLEGE, Birmingham—Joint Professor of Anatomy.

ST. MARTIN'S-IN-THE-FIELDS—Medical Officer of Health.

ST. MARY'S HOSPITAL MEDICAL SCHOOL—Medical Tutor and Pathologist.

ST. THOMAS'S HOSPITAL—Assistant-Surgeon.

[For Poor-law Vacancies see Poor-law Department.]

### MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

McKECHNIE, Daniel, L.F.P.S.Glasg., appointed Medical Officer and Public Vaccinator for the Escomb District of the Bishop Auckland Union.

MANSON, R. T., M.R.C.S.E., L.R.C.P.Ed., appointed Medical Officer and Public Vaccinator for the Howden District of the Bishop Auckland Union.

\*NICOLSON, David, M.D., late Assistant Medical Officer to the Convict Prison at Portland, appointed Assistant Medical Officer to H.M. Invalid Prison at Woking.

### BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication.

#### BIRTH.

MILES.—At Plympton Maurice, Devon, on June 26th, the wife of \*George Miles, Esq., Surgeon, of a son.

#### DEATHS.

ASBURY, Jacob Vale, Esq., Surgeon, at Enfield, aged 79, on June 21st.

\*BEALE, Lionel John, Esq., Surgeon, at 108, Long Acre, aged 74, on June 23rd.

\*DUNDAS, Robert, M.D., at 14, Gloucester Place, Hyde Park, on June 25th.

GOWING, William G., Esq., Surgeon, at Alfred Place West, South Kensington, aged 79, on June 12th.

HILL, Thomas, Esq., Surgeon, at Portobello, Edinburgh, aged 68, on June 10th.

LAMBE, Lacon W., M.D., of Henwood, Dilwyn, Herefordshire, at Torquay, aged 73, on June 20th.

FOR the future, the operations at Charing Cross Hospital will take place on Saturdays from 1 to 2 o'clock.

THE Infirmary of the Spalding Union Workhouse is to be enlarged at an expense of £1297.

DERBYSHIRE GENERAL INFIRMARY.—It is proposed to increase the medical staff by the appointment of a resident assistant house-surgeon, two dental surgeons, and a non-resident dispenser.

## OPERATION DAYS AT THE HOSPITALS.

MONDAY .....Metropolitan Free, 2 P.M.—St. Mark's, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.

TUESDAY .....Guy's, 1.30 P.M.—Westminster, 2 P.M.—National Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.

WEDNESDAY...St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.

THURSDAY...St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.

FRIDAY .....Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic Hospital, 2 P.M.

SATURDAY...St. Thomas's, 9.30 A.M.—St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 1 P.M.—Lock (Clinical Demonstrations and Operations), 1 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—East London Hospital for Children, 2 P.M.—Hospital for Women, 9.30 A.M.

## MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

WEDNESDAY.—Obstetrical Society of London. 7.15 P.M., Council Meeting. 8 P.M., Dr. Tilt, "On the Diagnosis of the least known varieties of Uterine Inflammation"; Dr. Copeman, "Notes of Cases of Interest"; and other papers.

## NOTICES TO CORRESPONDENTS.

ALL Letters and Communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen Street, Lincoln's Inn Fields, W.C.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

TO PURCHASERS.—To insure attention, it is requested that all orders sent to the Office for extra copies of the JOURNAL, be accompanied with halfpenny stamps for the amount.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

A YOUNG MEMBER.—The Midwifery Board of the College of Surgeons will not meet again until August, unless there should be several candidates desirous of obtaining the "L.M.". Inquire at the College after the ensuing "pass" examinations, if that month is not early enough for you.

DR. KIDD writes: "I think there have been very many cases of death from chloroform noted in the journals where it has been specified that the tongue has been drawn forwards with artery-forceps, but all to no avail."

## A STUDENT'S GRIEVANCE.

SIR,—I think it is a great shame that some men should be allowed to pass their preliminaries piecemeal in Scotland, while those who go to London have to pass all their subjects at once. I know two or three cases where a youth has gone to Glasgow or Edinburgh and passed in two or three subjects, and gone again next year and passed some more, and so on; and I do not consider it at all fair to those who pass at London, where it is a harder examination, and they have to pass it all at once. And I think it is a thing which ought to be noticed.

I am, etc., ONE WHO PASSED IN LONDON.

F.R.C.S.—On inquiry, we find your address is not known at the College, hence the cause of your not receiving the usual notice. You will, however, be able to record your votes. There are four vacancies.

## ARMY MEDICAL OFFICERS.

SIR,—Mr. Cardwell has stated in the House of Commons, in the discussion on the Army Regulation Bill, that in future the promotion of combatant officers is to be by selection for merit, and not by seniority. The rule at present, as regards medical officers of the army, is to let promotion, up to the rank of Surgeon-Major, depend on seniority, except in some very exceptional cases. Would it not be an act of justice to army medical officers if the Government would consent to apply the principle of promotion by selection to the medical as well as to the combatant ranks? If you were to lend your aid in advocacy of this principle, probably it might be adopted when the Bill is under the consideration of the Lords.

I am, etc., T. S.

MR. G. B. has written:—A "Member" will find the formula of preparation of the syrup of phosphate of soda, argemone, and strychnia, in Squire's *Companion to the British Pharmacopoeia*, 7th edition.

## DEATH FROM CHLOROFORM.

MR. G. C. COLES, in a note with which he favours us, referring to the death from chloroform at the Great Northern Hospital, of which we have already given an account, states that:—"The child's tongue was immediately seized with a pair of artery forceps, pulled forward to the right side of the mouth as far as possible, and retained in that position the whole time."

A COUNCIL FELLOW.—The election of Fellows into the Council of the Royal College of Surgeons on Thursday next will not close at 5 o'clock; and, as ten minutes must elapse after recording the last vote, you will see doubt be in time. Mr. Spencer Wells polled five votes last year, including 3 plumpers; 234 Fellows voted, about 70 less than the previous year.

NOTICE TO ADVERTISERS.—Advertisements should be forwarded direct to the Printing-Office, 37, Great Queen Street, W.C., addressed to Mr. F. H. HEATHCOTE, not later than *Thursday*, twelve o'clock.

F.L.S. (Sidmouth).—If the result of the recent Arts examination should be unfavourable to your son, perhaps he may be more fortunate at the September examination at Apothecaries' Hall, in which case he could enter on his hospital studies the following October, as you propose.

A STAFF-SURGEON.—Not having signed the Bye-Laws since your election as a Fellow of the College, you will not be allowed to record your votes at the annual election of Fellows into the Council of the College; you can, however, attend the festival the same evening. Mr. T. Carr Jackson is the Honorary Secretary.

## PRUDENTIAL PREVENTION OF DISEASE.

SIR,—It has given me very great satisfaction to see, by your issue of June 10th, that Dr. Acland has, in a recent lecture at the College of Physicians, called attention to the all-important question of over-population, as the main cause of infantile mortality, disease of children, and early death. I have long felt persuaded that all our efforts in the direction of the prevention of disease must be confined to benefiting the very few, until we doctors begin to understand the neutralising effect on all progress of the reproductive natus, which we, in common with all other animals, are the subjects of. Dr. Acland has well-shown that overcrowding and all the concomitants of under-feeding, bad air, and the like, are the inevitable consequences of the present "struggle for existence", so clearly seen in our midst by any observer who is acquainted with the theories of Malthus, Mill, and Darwin. When we are aware that, from 1790 up to 1875, the population of the United States doubled its numbers in twenty-five years, due allowance being made for immigrants and their offspring, from the mere powers of fecundity inherent in the human race (when it can get food, clothing, and shelter), we can easily imagine what an intense pressure there must be of population against capital in our little islands, or throughout Europe. Ignorance of these facts, as Dr. Acland truly observes, completely confuses those who wish to reason clearly upon questions appertaining to the prevention of epidemics, or the cure of pauperism; and my own acquaintance with medical men has revealed to me that but a very few of our body are at all aware of the existence of any such "law of nature" as that discovered by Malthus about the commencement of this century. The disease of poverty is the chief of all human diseases; because it causes infantile mortality, phthisis, scrofula and fever, besides being the main source of crime and misery. Yet many writers on medical subjects seem not to have made this diagnosis, or only imperfectly to have seen it occasionally. As to what should be the therapeutics of this malady, I am not so certain. Some persons, like Dr. Acland, as it seems to me in his lecture, following Malthus, recommend prudence, or late marriages; but, then, late marriages surely often lead to prostitution, and end, in both sexes, in the lunatic asylums. Emigration, as Professor Fawcett says, is a delusion and a snare. The French prefer to limit their families to two children. Where is truth to be found amid such a mass of remedies? Discussion alone can answer us this query; and I do hope that Dr. Acland's example will tempt some equally able man to hazard a solution of this difficult question—How are over-population, and poverty and diseases thus caused, to be avoided? I am, etc., CHARLES R. DRYSDALE, M.D.

99, Southampton Row, W.C., June 10th, 1871.

WE are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The New York Medical Gazette, June 24th; The New York Medical Record, June 15th; The Boston Medical and Surgical Journal, June 15th; The Madras Mail, April 17th; The Shield, June 24th; The Philadelphia Medical Times, June 7th; The Philadelphia Medical Independent, June 10th; The Lancaster Observer and Morecambe Chronicle, June 3rd; Supplement to the Isle of Man Times, June 17th; The Glasgow Herald, June 24th; The North British Daily Mail, June 23rd; etc.

COMMUNICATIONS, LETTERS, &c., have been received from:—

Dr. T. K. Chambers, London; Dr. J. Crichton Browne, Wakefield; Dr. Heaton, Leeds; Dr. Day, Torquay; Mr. G. Jones, Birmingham; Mr. R. T. Manson, Howden; Mr. G. C. Matthews, Moate; Mr. E. Gaylor, Belper; Dr. D. Nicoll, Bradford; Dr. C. Kidd, London; Dr. Farquharson, Berlin; Dr. Protheroe Smith, London; Mr. Spencer Wells, London; Dr. W. Ogle, Derby; Mr. Warren, Northampton; Mr. Donnelly, Dublin; Dr. Clothier, London; Dr. Underhill, Great Bridge; Mr. S. J. Knott, London; Dr. Wade, Birmingham; Mr. Sewill, London; Dr. C. J. B. Aldis, London; Mr. Moody, London; Dr. R. Elliot, Carlisle; The Registrar-General of England; The Secretary of Apothecaries' Hall; The Registrar-General of Ireland; Mr. T. M. Stone, London; The Registrar of the Medical Society of London; Our Dublin Correspondent; Mr. William Adams, London; Mr. Holthouse, London; Mr. G. Miles, Plympton; Dr. T. T. Pyle, Sunderland; Mr. Edwin Pears, London; The Secretary of the Obstetrical Society; Mr. F. Pollard, London; Mr. J. Sampson Gamgee, Birmingham; Dr. A. W. Edis, London; Dr. Littleton, Plymouth; Dr. Skinner, Liverpool; Dr. Venables, Blackheath; Mr. Lawson Tait, Birmingham; Dr. Nicolson, Woking; Mr. Campbell De Morgan, London; Mr. Nunn, London; Mr. E. Bellamy, London; Mr. R. H. B. Wickham, Newcastle-on-Tyne; Dr. J. B. Tuke, Cupar Fife; Dr. Gordon, Dublin; Mr. B. Shaw, Battersea; Mr. C. R. Price, St. Leonard's-on-Sea; Mr. Maunder, London; Mr. Collier, Ripon; Mr. Fairlie Clarke, London; Dr. Blandford, London; Mr. G. C. Coles, London; Dr. E. Waters, Chester; Dr. Hilliard, Birmingham; Mr. W. B. Blanchard, London; Mr. T. Watkin Williams, Birmingham; etc.

## BOOKS, &amp;c., RECEIVED.

The Second Annual Report of the West of England Sanatorium or Convalescent Home for 1870-71. Weston-super-Mare; 1871.

The Modes of Origin of Lowest Organism: including a Discussion of the Experiments of M. Pasteur, and a Reply to some Statements by Professors Huxley and Tyndall. By H. Charlton Bastian, M.A., M.D., F.R.S. London; 1871.

## THE HASTINGS PRIZE ESSAY,

1870.

ON DIGITALIS: ITS MODE OF ACTION  
AND ITS USE.\*

By J. MILNER FOTHERGILL, M.D.,

Senior Resident Medical Officer to the Public Dispensary, Leeds.

*Manner of Action.*—We have seen in a previous section how the administration of digitalis in physiological experiments is followed by increased contraction. It is obvious that this can only take place in one of two ways, viz., by stimulation of the cardiac ganglia, or by paralysis of the fibres of the vagus. These are, then, the two theories which exist. We will consider, first, the theory of Traube—that of paralysis of the pneumogastric fibres.

1. *Theory of Traube.*—This theory took its rise in the tumultuous movements which result from the section of the vagi. When both vagi were cut, tumultuous and irregular vermicular action was observed to result. That is, the nerve-force was still passing into the sympathetic, which were in full activity, while no longer was there any co-ordinating power in action. It must be admitted on the side of Traube, that certainly digitalis did not act so rapidly on animals where the vagi were cut (see the experiments of Handfield Jones); but, on the other hand, it is more difficult, on his theory, to see how it could act at all after that. Also, section of the vagi only produces death slowly, and that by hepatisation and disorganisation of the lungs; and the most complete paralysis could not be more effective than section. Now, the administration of digitalis in full doses brings the heart to a standstill as a primary action, and that, too, at an early period. There is no apparent connexion between the administration of digitalis and section of the vagi, except an increase in arterial tension, as tested by the hæmadynamometer—the test used by Traube. Winogradoff, from a similar series of experiments to those of Traube, came to opposite conclusions. Niemeyer states that he has clinically been compelled to emancipate himself from the bonds of Traube's theory.

2. *Theory of Stimulus to Cardiac Ganglia.*—This theory was announced by Dybkowsky and Pellikan abroad, and supported by Handfield Jones, with Fuller and others, in this country. This theory is, that digitalis acts as a stimulus to the cardiac ganglia, and thus produces the increased muscular contraction. It is almost needless to remark here, that in no way could the stimulus to the nerve-ganglia manifest its results except in muscular energy—i.e., increased action of the muscular fibres under their control. The increased action and irregularity can as easily be conceived to result from a disturbance of balance through over-action of the cardiac ganglia, as in paralysis of the opposing fibres of the vagus. That this irregularity does result, is unquestioned by either side. In order to settle the question of these opposing theories, Eulenberg and Ehrenhaus took out the heart of a frog, and dipped the lower end, or apex, into a solution of digitalin; the rhythmical action which goes on under the action of the cardiac ganglia, when the heart of a cold-blooded animal is cut out of the body, and when no longer any nerve-force is coming in from vagus or sympathetic fibres, and which contrasts with the tumultuous action which follows section of the vagi when the other nerves are intact, was interfered with; if the solution were weak, the action was rendered slow and irregular; if strong, the motion was stopped. Some light, too, is thrown on this intricate subject by observing the effects of digitalis on other organs where no inhibitory action of the pneumogastric exists. Dickinson found the action of digitalis beneficial in menorrhagia, from its contractile effect on the arterioles. Malan watched the contraction of the capillaries (to dispute whether they are capillaries or arterioles would be out of place here) of a frog's foot under the microscope—an experiment corroborated by the writer. On the application of an aqueous infusion of digitalis leaves, a contraction of the vessels of the web was found to follow, and to proceed to such an extent as to interfere materially with the circulation, bringing it nearly to a standstill: of this some further account will be given in the section on the action of digitalis on capillaries. The inhibitory action of the pneumogastric could have no place in these last named observations. And from the obvious difficulty attending Traube's theory, and the direct evidence in favour of the other, I am led to unhesitatingly side with the latter. The action of the

stimulated cardiac ganglia is too much for the action of the vagus; and thus, instead of an almost synchronous contraction, as is normal, the action is seen to be distinctly vermicular. A long peristaltic contraction is followed by an imperfect diastole and distension, until a state of permanent systole is attained, exactly corresponding to the process of the application of electricity to the sympathetic, and in no way analogous to the results of section of the vagi—than which no paralysis could be more complete as regards abolition of function. The results, too, of the administration of digitalis after aconite poisoning had been established, would necessitate the theory of aconite acting as a stimulus to the fibres of the pneumogastric, if Traube's theory of the action of digitalis were true—a conclusion which is not warranted by what we know of aconite.

*Action on Capillaries.*—The action of digitalis on the capillaries, as observed by M. Malan and the writer, is in unison with the above mentioned theory of its action on the cardiac ganglia. From the same portion of the splanchnic system arise the vaso-motor system of nerves, regulating the size of the lesser arteries and arterioles, but not capillaries. Be this as it may, and granting that capillaries do not possess the power of contraction, and that, therefore, the vessels must have been arterioles if they contracted, unquestionably the application of infusion of digitalis to a frog's foot produced contraction of the vessels of the web. While the corpuscles had before been coursing down them in single file, they were now arrested and passed with great difficulty, in many parts of the field being arrested altogether. The flow through the capillaries was no longer a continuous flow, in which the impulse of each ventricular contraction was lost; the circulation was by pulses corresponding to each beat of the heart, during which each corpuscle moved about twice its own diameter forwards. On the application of digitalis systemically, consequent increased ventricular contraction became conspicuous, each corpuscle now travelling about four times its own diameter; but the general condition was not altered. Further observations as to its effect on the capillaries may lead to further knowledge; and the writer regrets that circumstances have interfered with his prosecution of this branch of the inquiry. Enough, however, has been observed to demonstrate that digitalis has a direct action on the minute vessels; and in practice that fact must not be forgotten when digitalis is administered for the sake of its effect on the muscular walls of the heart, and the condition of the vessels between the heart and small vessels—viz., the arteries—is registered.

*General Observations as to its Effects when Administered Clinically.*—It may be well to give a summary of the effects of digitalis when clinically watched, before proceeding to instances of particular disease. The early administration of digitalis was conducted on the theory of its being a cardiac sedative. The reason for this theory was, that palpitation and irregularity were relieved by its administration; and hand in hand with this went on the theory of these derangements, especially palpitation, being over-actions of the heart. That in reality they are evidences of deficiency rather than excess of power on the part of the heart, we now all know. With the exception of excitement, which is visible in its effects on the pulse, we now know that there is no such thing as over-action of the heart. Hypertrophy is, without exception, a compensating growth to overcome some obstacle; though Niemeyer would except one class of cases where he considers it a mere result of plethora. We can no more imagine a heart undergoing spontaneous uncalled for hypertrophy, than we can fancy a similar action going on in the bladder or bowel. It is too obvious that the increase in muscular tissue is called forth only by a necessity for it. Palpitation may occur with hypertrophy; but it merely gives evidence that that hypertrophy is sufficient. Palpitation is an evidence of over-taxation, whether it occurs in hypertrophy or in dilatation. Nevertheless, the administration of digitalis is followed by a quieter action, but that is by its restoration of the conditions to the norm, or an approach to it. Under digitalis, the pulse becomes steadier, firmer, and less compressible; the excited stroke of palpitation is steadied into the normal, quiet, effective contraction; the system is relieved; dyspnoea, the external witness of pulmonary congestion, is abated; the deficient secretion of urine, which tells us that the pressure on the glomeruli of the Malpighian bodies is lessened, is improved, and free secretion takes its place: dropsy is thus often relieved. The general condition of cyanosis is abated; there is evidence of a better circulation throughout the system generally. Frequently, the gradually widening circle of troubles which are involving the patient's existence, gradually diminishes after an improvement is inaugurated in the circulation. The spell which bound the system in a load of ever-increasing fetters is broken by the administration of a drug whose action is unquestionably to produce better, more complete, ventricular contraction; and in that, and that only, I believe the magic lies. When we consider the extreme tendency there is for a condition of cardiac engorgement, or distension to

\* Continued from page 7 of last number.

result from any prolonged debilitating cause, or acute disorder, and that, too, especially in the right or truly venous side of the heart; when we consider how that again tells on every excretory organ, from the lungs in front to the kidneys behind, and how that leads directly to non-excretion, and how blood-poisoning is engrafted on partial blood-stasis; how the left side of the heart is encumbered between the two burdens of poisoned blood and venous congestion—we can readily appreciate a drug which will enable these chambers to more completely empty themselves, and thus to direct better blood-propulsion, and can understand its extreme therapeutical importance. It is of the utmost importance that we really understand in the administration of digitalis what we can fairly expect of it, what it may be fairly presumed to be able to do, and what experience tells us it has done before. It is obvious that when all is well, neither we nor any patient would wish to administer it or any other drug; we now know that there is no deviation from health except in a downward direction. It is obvious that the most perfect action of the heart is when we are unconscious of its labours. It is equally obvious that those symptoms which tell us that it is at work, are really evidences that the heart is labouring, in both senses of the word. It is for a condition of inability on its part that the physician is consulted by the patient; and though it is possible that now and then its efforts can be strangled by a sedative, or allayed by a narcotic, it is equally obvious that neither can be styled a scientific treatment; for permanent relief we must look for something which will really aid its efforts; and to this, and for the condition under which digitalis ought to be administered according to the experience of the writer, the next section will be devoted.

*General Considerations continued.*—The conditions under which the physician finds his patient run somewhat in this fashion. The patient complains of a feeling of anxiety about the precordia, with a general unaccountable anxiousness—a sense of difficulty of breathing, which is notably increased upon exertion; he has fluttering about the left breast amounting to palpitation upon effort or exercise; the pulse is irregular, or may be regular but compressible; then come a dusky complexion and impeded respiration. Here, then, is a condition of cardiac engorgement which would scarcely be disputed, whether as a passing condition or as one in a series of similar attacks. On examination of the case, there can usually be found a feeling of diffused impulse on palpitation, a large mass apparently being thrown into contact with the thoracic walls; percussion reveals an increased general dullness, frequently in the direction of the right side of the sternum. Auscultation communicates to us the further information that there is a short slapping sound, with or without irregularity, or, perhaps, evidence of laboriousness—a heaving swell with obvious effort, which, however, is not followed as effect by that impression on the arteries we might look for; and, finally, there is a something beyond this utterly undecipherable by words: a peculiar significant information conveyed, which experience and repeated observation alone can understand or interpret. Those who have made heart disease a study will readily understand and supply that which I feel incompetent to convey. Or, in other circumstances, the patient has a tickling cough, feels short of breath on exertion, has a slight attack of bronchitis, or may be no particular ailment; the pulse is small or feeble, but, on casually applying a stethoscope, there is found a state of cardiac excitement with some irregularity in time—action, like imperfect palpitation, but without any evidence on the radial pulse. It is nevertheless there, and percussion soon demonstrates that there is increased dullness to the right side of the sternum, and auscultation reveals corroborative information in adding a marked accentuation of the second sound at the pulmonary valves. The aggregation of sounds demonstrates that there is embarrassment and also laboriousness in the right ventricle; it is not likely to be accompanied by any effect on the radial pulse; and even the discriminating sphygmograph is thrown out, for there is no increased arterial tension anywhere where it can be applied. The trouble is going on in the right side, the diminished amount of blood passing into the left ventricle is insufficient to allow any impression to be made on the arteries even if, as is very probable, the left ventricle is acting somewhat excitedly. From the number of fibres which belong equally to the right and left ventricles, and can be traced into each (see the works of Searle and Pettigrew), such community of action, even where there is no call on the left ventricle, is almost unavoidable. These conditions, and more so the latter one, are common enough when searched for, especially among the out-patients of a public institution; in fact, we are learning that a condition of engorgement of the cavities of the heart is quite usually met with; and, in fact, if we are to believe MM. Cyon, von Bezold, and Claude Bernard, a special innervation is in action to permit it. How far this condition may be a necessary one in the present state of science, we are unable to determine; we can, however, readily discover this condition, and more easily calculate the amount of mischief which

is actually present therefrom, or likely to result from its continuance. Without entering here into the troubled waters of a consideration of the existence and importance of a condition of temporary distension in acute disease or passing conditions, which is reserved for a later section, we are familiar enough with this condition when fully established as dilatation, with or without hypertrophy. A permanent enlargement of the ventricular cavities, and more commonly so of the right one, is a condition the reverse of rare. While frequently found among persons advanced in life, it is far from uncommon among younger people. These are the conditions which physiological research has pointed out as suitable for the administration of digitalis as a therapeutic agent; and clinical observation confirms the view. It is proposed, then, to consider the general condition of distension or dilatation; the manner in which the drug acts; the other conditions, causal or consequential, with which the condition is connected; and the especial circumstances in each condition which would encourage or forbid its use.

*Mode of Action in Distension or Dilatation.*—It is in this condition of distension that the advantages of the administration of digitalis are most evident. In this condition of deficiency of expulsive power, the heart-walls yield. The heart is distended, and in contraction only gets rid of a little blood off the top, remaining more or less full in systole. It is more or less full before the distended auricle and veins behind pour in their contents under the increased pressure of distension. It is in the partially filled condition of the ventricle that the difficulty lies essentially. If the ventricle were not partially full, the auricle and veins would be somewhat relieved; but there is what would fill well an empty ventricle waiting to be discharged into one more or less full to begin with. The action may be moderately regular on quiet being maintained, but it is at once disturbed on motion, especially if this be at all active; and then we get palpitation and irregularity, or even intermittency, the regular action being again restored by quiet. There is a constant contest going on between the stimulus of the contained blood and the inhibitory action of the pneumogastric fibres. The distension excites the muscular walls to overcome the restraining influence; for, without the stimulus of distension, the walls could never overcome the inhibitory action of the pneumogastric, the *vis inertiae* of the blood to be driven; and action still further deranges the balance by making still greater calls on the muscular walls. In fact, the heart is in a state of over-distension, and in a condition both analogous to, and homologous with, an hypertrophied bladder attempting to overcome the obstruction of an enlarged middle lobe of the prostate. The over-distension goads the organ to such a contraction as shall relieve that over-distension, but only so far, and no further; there is no complete contraction. An incessant play goes on between the condition of over-distension and the restraining fibres of the vagus; the balance between the muscular walls and their work remaining confessedly disturbed. In this condition, the administration of a drug whose physiological action is to stimulate the sympathetic ganglia, and thus the muscular fibres under their control, into excessive contraction, is almost the only means of restoring the equilibrium. This is beautifully exemplified in the heart of a frog, when paralysed and almost brought to a standstill in diastole by aconite; the heart is distended, globular, and, in every respect but that of chronicity, in the condition of a dilated or distended heart. Then administer digitalis, and watch the result. The distended globe, just pumping painfully a little off the top of the contained blood, and that at long and irregular intervals, begins to contract with more vigour; each ventricular systole is more and more complete; and the bulk of blood remaining unexpelled—and that is the great point—becomes less and less in quantity. Shortly, the distension in diastole is shortened, the distension and contraction come gradually back to the norm, the irregularity in time is lessened, and a complete restoration results. But if the experiment be carried still further, spasmodic contraction or the condition of concentric hypertrophy sets in, irregularity again makes its appearance—for the balance is now disturbed in the opposite direction; in fact, the symptoms of digitalis-poisoning are brought out, and ultimately the heart is brought to a permanent standstill in systole. Thus in a distended heart, only a longer time is requisite, and, of course, the cause of the original distension must be overcome; so that the conditions are exactly equal, and longer time and an artificial compensatory hypertrophy is necessary to maintain the balance thus temporarily restored. When this condition of distension is only of short duration, as seen in people who have been overworked and overtaxed for a short period only, but presents all the appearances, signs, and symptoms of cardiac dilatation, the restoration of the natural balance by digitalis may be quick and withal permanent. Certainly I have seen such cases. The experiments of W. T. Gairdner on Groux, the man without a sternum, show that the ventricular chamber undergoes a certain amount of expansion under passing circumstances, a normal distension in fact; for distensibility without abolition of function is a peculiar property of

involuntary muscular fibre; but when distension is excessive, or the tissue degenerate, however, abolition of function may, and certainly does, take place. The experiment may be tried on any thin muscular man—viz., place the tip of your finger on the exact apex-beat, and bid him hold his breath; the right ventricle dilates until the apex-beat is lost behind the distended ventricle, which acts like a water-cushion between the left apex-beat and your finger. Still keeping your finger in its place, tell the man to breathe again; the distended condition passes away, and soon no trace of it remains. Now, all the time the heart has been beating away, and there has been no abolition of junction. Claude Bernard has gone so far as to suggest that a normal distension of the heart takes place through the action of the depressor nerve of the heart of Cyon and Ludwig, and that the heart can undergo a certain amount of accommodation to the blood-vessels, and by dilatation become, for the time being, a regulating reservoir. Without endorsing the theory of Claude Bernard, it must certainly be admitted that the condition is unquestionably common enough, and is not detected because, probably, it is not sought for: it is intimately related to the short, weak, fast pulse, which in a remarkable manner is rendered slow by digitalis, with great improvement in the systemic symptoms. Now, what has gone on? The condition is one of distension; the ventricle, just at the point of distension always, from inefficient contraction, soon becomes so over-distended as to be excited to contraction in spite of the vagus; the pulse-wave is feeble, for only a small quantity of blood is thrown into the aorta, and the elastic walls are not sufficiently distended to bring out a good pulse; the needs of the circulation are not properly supplied, and the body generally partakes of the feebleness of the circulatory centre. Then administer digitalis, and soon the pulse falls, say from 130 to 72; the radial pulse is much improved, being fuller and more sustained, and relief of the system is attained. Sometimes, but rarely, we read of a curious irregularity of rhythm accompanying the alteration, viz., sometimes a series of beats at the rate of 130 per minute, and then another series at the rate of 72; it seems as if it were some time before the old habit was broken. Never having met with such a case, I cannot explain the condition. The slow pulse is due to the ventricle making a more complete contraction, taking up, of course, more time over it, and requiring longer time for distension again. In fact, to again use our old simile of the bladder, the condition of distension is like the bladder behind the enlarged prostate, only contracting to the extent of over-distension—soon full, because never empty; while the altered condition bears more resemblance to the normal bladder capable of complete contraction, and consequently requiring longer time for distension. The heart in distension is incessantly at the point of over-distension, and is acting unnaturally quickly; the administration of digitalis, by producing more perfect contraction, relieves this condition of irritable, or, rather, irritated distended ventricle, while, at the same time, more complete contraction produces more thorough aortic distension, and thus brings out more thorough arterial recoil or systole; that, again, gives relief generally to the systemic symptoms, and also permanent benefit as an ulterior result. It must be borne in mind here that the contraction of the ventricle fills the vessels and distends them; the recoil of the elastic arteries completes the propulsion of the blood. The series of altered actions consequent upon increased contraction, run in the following order or sequences; and it may be desirable for the sake of lucidity to arrange them in a series of propositions, each depending on the one before, like a logical syllogism. The effects of increased contraction are, then:—

1. Increased arterial distension and tension, which give relief to the systemic symptoms, and further causes
2. Increased arterial recoil. This is the propelling power for the coronary arteries; and thus arterial recoil means
3. Increased or improved coronary circulation; and that, in its turn, produces
4. Increased nutrition of the heart, which results in
5. Compensatory hypertrophy. In connection with these, we have also to consider
6. Atheroma and fatty degeneration of the heart-fibres.

[To be continued.]

**PLUGGING THE NOSTRILS AS A PRECAUTIONARY MEASURE.**—M. Verneuil, in a paper published in the *Bulletin Général de Thérapeutique* for May 30, recommends plugging of the posterior nares as a precautionary measure in all cases of operation on the face where there is danger of the passage of blood into the pharynx. Besides preventing this as long as the soft palate is uninjured, the plugging also, M. Verneuil says, enables chloroform to be given during the whole operation. It ought to be done before the induction of anaesthesia is commenced.

## HOW TO REFORM OUR PROFESSIONAL GRIEVANCES.\*

By W. OGLE, M.A., M.D.Cantab., F.R.C.P.Lond., Physician to the Infirmary, Derby.

GENTLEMEN,—By accident rather than by my deserts I find myself in the honourable position of President of the Midland Branch of the British Medical Association. It is impossible that any one can forget—least of all that I should not be painfully conscious—that one who has gone to his rest was elected by you to preside on this occasion. Mr. S. W. Fearn occupied a first position in the profession in this locality; and no less for his ability as a surgeon than for his sterling worth and high professional character, we all should have rejoiced to see him in the Presidential Chair. An all-wise Providence has decreed otherwise, and upon me, by your favour, has devolved the difficult and almost impossible task of worthily succeeding him.

I crave your indulgent hearing of the remarks that follow. They are the result of much earnest thought, and, so far as they shall be worthy of your acceptance, are the outcome of conversations that I have had with many of my seniors. Throughout my professional life it has been my happy privilege to be thrown much among my elders, and with them I have frequently discussed questions which, for lack of a better term, I may call our "professional grievances". I venture to think that our time will not be misspent if I take up some of these grievances and invite you to look at them in their different lights, and ask you to consider whether the day has not arrived for us to get rid of some of them. If, with your assistance, I succeed only so far as to break the ground for future more skillful cultivation, we shall not have met in vain. Who is there among us that has no grievances? Is the parish-doctor free? or the club-doctor? or the general practitioner? or the physician? There are not wanting those who feel it something of a grievance that there should be this classification. Why should the title of "Physician" be restricted to a few? or, if restricted, be a more honourable one than any of the rest? I for one, as one of the privileged class, am quite prepared to see the distinction removed, if only the levelling be a general upraising, not a general depressing, of the profession. In the work of attending upon the poor as a servant of the state, still less of attending on the poor under an arrangement made by themselves, as the fruit of their own forethought and self-dependence, and in the arduous and responsible duties of "family doctor", there is no necessary inferiority. The physician who says that there is, does not know the true dignity of his own position. But we are dealing with things as they are, and are, therefore, accepting these distinctions merely for convenience of illustration.

Accordingly, I begin with the parish doctor, subject to the control of men who, to a proverb, "have no idea beyond that of keeping down the rates". There are, no doubt, honourable exceptions in Derby, perhaps, and elsewhere, which will occur to every one; but none know better than parish doctors that a board of guardians is an acknowledged type of parsimony, and exceptions here or elsewhere only serve to make the rule more palpable. From these his masters he receives in many cases scarce enough to cover the cost of drugs; he has, moreover, an acreage of duty so extensive as to make his work impracticable. Yet he is obliged to hold on for fear of leaving an opening for a rival; and after all he gets from the public often not even thanks. There are those among the poor who call him "blessed"; but when the time comes that he wishes to retire from his onerous duties, the public makes little or no sign of gratitude or of sympathy.

Take next the case of the club-doctor, striking a bargain with the committee at the "Fox and Goose". He receives a small capitation fee on each member, with the chance of attending the member's wife and children. This is the bait held out to the young, and too dearly purchased to be given up by the old, though they have long since found out the truth of the proverb, "All is not gold that glitters". The capitation fee is to include everything—no extra fees, no charges for physic, no protection against the admission of well-to-do tradesmen, small farmers, with the publican himself, at whose house, and for the good of whose house, the club meets—of many, in short, who join the club for nothing else than to be able to claim medical attendance and physic at a nominal cost when they are sick. And, worst of all, to an honourable, high-minded man, there is the degradation of being in the eyes of the public, of the profession, and of even the members themselves, "only a club-doctor".

But leaving these the so-called lower ranks of the profession, how fares it with the general practitioner—the man who perhaps eschews parish work and will not condescend to club-practice?

\* President's Address, delivered at the annual meeting of the Midland Branch, 1871.

Even the busy, thriving man, the envy of many, who has perhaps bought a good practice, and is able to keep it together; or has, by steady probity, perseverance, ability, and tact, worked his way up to be one of the five or six leading men in a populous thriving town—even such an one has something to recount as a serious set-off against his seemingly enviable position. Even assuming that his receipts are considerable, he has in the first place the nuisance of dispensing, which he cannot afford to give up; there are also not a few bad debts, as well as heavy expenses; his charges, also, with "particulars if required", are scrutinised more than is pleasant to a sensitive, honourable-minded man; and for one patient that treats him as a friend and a gentleman, from two to ten will look upon him as a kind of upper servant who must be kept in his place, or as a sort of "ogre" who is to be avoided as long as possible and dispensed with as speedily as possible. However eagerly and peremptorily he may be summoned when his presence seems to be a necessity, he is liable at any moment to be dismissed, to find himself supplanted, to have his best endeavours forgotten, or even misunderstood and turned to his own disadvantage. And at best he is exposed at every hour of the night as well as the day, without any extra protection against needless calls, so that he is a stranger for weeks and months together to the comforts of family life. A social dinner like the one which we have in prospect, or a quiet evening with his wife and children, and the hallowed rest of a Sabbath day, are to him unknown luxuries. Surely the gains of such labour must be great! some great inducements in the shape of honour or emolument must be in store! But no; experience can quote few who can afford to retire upon their earnings. A visit to the office of the Royal Medical Benevolent College would undeceive many who talk about doctors' profits; and as to honour, medicine obtains no such recognition as either divinity or law. Who, then, can be surprised to hear even the well-to-do practitioner declare that no son of his shall enter the profession—that he would sooner (as I have heard it said more than once) "see him break stones upon the road"?

But, again, suppose the means are not wanting, and that *per saltum* a man can begin at the top of the tree—can be independent of general practice, or at least can pick and choose, undertaking none but of an easy kind; he has no dispensing; it would be *infra dig.*; he is seldom called up at nights; his Sundays are his own if he pleases; his fee is understood to be nothing less than a guinea; he holds as many hospital appointments as he pleases—can obtain them in the country for the asking, and even in London without much difficulty—has such an one any grievance? His grievances are of a different kind, but none the less real. There is very little encouragement to such an one to support the dignity, *i.e.*, to discharge the special duties, of his position; the pressure is quite the other way. It will "pay better" to make himself notorious in a puffing, pretentious way—as by giving advice gratis, not merely at the hospital, but on particular days and at particular times, which must be proclaimed aloud; or by writing a book, or by adopting some other way of advertising himself, than by doing his own business quietly—a little it may be, but that little well. It is almost impossible to do so. He finds himself in an undefined region of practice—neither in general practice nor in consultation practice, but between the two; accordingly, the acknowledgment that he receives is of a nondescript character; his fee is not a guinea, nor even "a guinea or nothing", but a fraction of a guinea or nothing. For the guinea (if not vexatiously shorn of its shilling), two or three visits are expected; whilst the guinea a mile extra is reduced to two guineas for three miles even in the metropolis, and in the country to half a guinea a mile, to a third of a guinea a mile, to smaller fractions; if he will accept them, till it becomes a question whether the mileage will cover comfortably the cost of cab-hire. The tendency of all this is to discourage first-class endeavour, to encourage a slothful mode of doing his work—and this to a man who *loves* his profession is a grievance. Even his duty in connection with public hospitals partakes of the same character; a large portion of it is more routine, and, as a natural consequence, the appliances at command are often of a very second-rate description. It naturally follows that the appointment of physician to a hospital does not confer the honourable distinction that it used to do, nor is it the same introduction either to first-class practice or to first-class society. By first-class practice I mean, of course, consultation practice. And here let me not be misunderstood; I count it no grievance, but the contrary, that consultations should pass into the hands of those who are engaged in general practice; but that consultations should seldom be held, and, when held, should be attended with so much difficulty, so much chance of injuring a professional brother, and so little chance, in comparison with what might be, of benefit to the patient, is a great grievance. Under these and other such disabilities the class of which I am now speaking is fast becoming extinct. I say this with no bitterness. I have already intimated the condition under which I should hail with satisfac-

tion this consummation. Let general practitioners become physicians; but the converse—*absit omen!*

Besides these "class" grievances, there are others which all alike feel more or less. There is counter-practice—a custom largely prevalent, whereby druggists who have no legal qualification prescribe, as well as dispense prescriptions.

Then there is the hydra-headed grievance of quackery—quackery sanctioned by the legislature and quackery which defies the law—quackery without, and, alas! quackery within, the profession itself. Add to this, that the public never lose an opportunity of giving a doctor a rub. Individuals may think and speak highly of individuals in the profession; every one thinks his own doctor a "none-such", at least for the time being; but the good-will and praise, even of one's own patients, is so commonly goodwill at the expense of all the rest of the profession, that no one whose heart is in the right place can feel it otherwise than as a professional grievance to be thus exalted. If further proof were needed of the disability under which the profession generally suffers, look at the doctor put upon his trial for malpractice. The cardinal principle of English justice is almost reversed; instead of considering him innocent till proved guilty, a doctor is held to be guilty until he can prove his innocence. This is the more oppressive, in that an unqualified quack will escape scot free under the very same circumstances from which the legally qualified practitioner suffers heavy loss.

This is a dark picture; and though it be ever so true, and true it is that most of these clouds have a silver lining (at least to every one who is devoted to his profession, for to such there are charms—scientific, philanthropic, social, and religious, using the term in its widest sense—which are rather intensified than lessened by the trials which accompany them), nevertheless it must be confessed the picture is sombre, and fully justifies my challenge at the outset, "Who is there among us that has not his own particular grievance?"

But let us not forget that there is another side of the question. *Audi alteram partem*, say the patients. If parish doctors are overworked, not paid, and little thought of; if club-doctors are imposed upon and a bye-word; if general practitioners are servants and leave no inheritance behind them; if physicians have little less than the shadow of their former dignity; if the whole profession is depreciated and does not occupy a position to which, in virtue of its important and responsible duties, it feels itself justly entitled; what of the patients—club-patients, pauper patients, private family patients, and physicians' patients, hospital and other? Though the pauper often receives an amount of attention and consideration regardless of cost, fatigue, and even of life itself, which makes many a despised parish doctor a veritable hero, has the pauper patient no grievances? There is an old proverb, "Dead men tell no tales", and this is true of dead paupers. The provision made for them is generally so utterly inefficient that suffering is inevitable, however great the energy, the self-denial, yea, the self-sacrifice, of the parish doctor.

Again, club-patients find to their cost that *my club-doctor* is a very different person from *my own doctor*. Perhaps it so happens that the one selected by the club is the very one against whom the member voted; or he may live so far off as to be practically beyond reach; or, if there be nothing more against him than the knowledge that the terms under which a medical man undertakes a club are not satisfactory, all the service rendered is suspected, and it (physic included) is assumed to be worth no more than the little or nothing that has been paid for it. There is, in short, wanting in the transaction that first element of success—the element of confidence. Aud to this, if the wife or child be ill, he does not feel free to employ any one but the club-doctor, and this curtailment of his liberty tends to make him dissatisfied; so the club-patient finds, when it is too late, that the system on which he depends breaks down.

Passing on to private practice, we often hear of ruinous long doctors' bills—of attendance for days, and weeks, and months, and the patient little better. We hear ourselves accused of prejudice against this and that clever person—of unwillingness to try this and that new mode of treatment. We are blamed for coming too late, we are blamed for arriving too soon; and at best, as already intimated, if there be one doctor in the world who is perfect, his reign is short, and there is only one. These are some of the ordinary grievances urged by patients—grievances which make many an one either do without a doctor or take refuge in quackery. And as to physicians' patients—using the term in its conventional sense—when a consultation is desired, there is so much difficulty in the way, so much fear of giving offence, so much questioning about who shall be called in, so much mystery when the second doctor does arrive, so little apparent result from the transaction—in a word, so large a fee and so little for it, that we must admit that these are grievances, or something very like them.

And what of hospital and dispensary patients? Surely here, where so

many thousands are expended, and where the patient has to pay nothing, the patient can have no grievance. My experience of dispensary work and of hospitals is probably as large as, or larger than, that of anyone here present; and it is my very decided conviction that hospital and dispensary patients in the long run, and in one way or another, as much as any class in the community, have grievances neither small nor few. Put yourselves in their places. Suppose yourselves now for the first time in your lives obliged to go to a hospital or to a free dispensary for medical aid. This is probably the very first time you have been obliged to beg: but, passing by this and all such social considerations, important though they be, and judging of the circumstances simply on the ground of efficiency, think of the increase to a man's suffering from the delays in obtaining the assistance needed. First, there is a letter to be procured; then he has to wait for the day of admission; the proper day arrives, but it is not the day on which the doctor of his choice attends at the hospital, so he has to wait another week, or perhaps a fortnight; and then, though the day be wet, windy, or cold, and he likely to get as much harm on the way as good from the visit, there is no alternative but to go, or to wait another fortnight or three weeks. At last, however, he is admitted; but even then the doctor may have been called away—may be gone for a holiday, or may be ill himself. But supposing yourself to meet with none of these minor drawbacks, and that the goal is attained—you have arrived at the proper time, on the proper day, and the doctor of your choice is there too; still there is the ordeal of the waiting-room, surrounded with others like yourself—some not so ill; others, it may be, worse. Imagine yourself one of twenty, forty, or more, waiting for your turn; and then four minutes and a quarter is the average (and this is a large one) of the time that you will have devoted to your case. Then you wait again for the physic, subject once more to the inconvenience and dangers of a crowd; and then you have your journey home, and in another week—not sooner, whatever may have happened meanwhile—you run the gauntlet again, with this difference, that a minute and a quarter is now your allowance; and so on. And the more ill you are, the worse it is. If you are so ill as to wish to be an in-patient you must wait the longer, for in-door letters of recommendation are less easily obtained than "out", there being fewer of them; also the same rules as to admission must be observed, and there is the additional chance of being sent home again after all, because there is no room. Then after admission there are, in nine hospitals out of ten, regulations which, if you were the patient, you would think very hard. Governors, boards of management, even the doctors themselves, have often very little idea of these grievances, simply because they do not put themselves even in imagination in the place of the patient. By this simple process, however, which is but carrying out the golden rule, "Do unto others as you would be done by", it will be found pretty generally true, that, for most of doctors' grievances, corresponding ones might be urged by the doctors' patients.

[To be continued.]

## A STATISTICAL ACCOUNT OF TWO THOUSAND CONSECUTIVE CASES IN MIDWIFERY.

By GEORGE JONES, M.R.C.S., L.M., Birmingham.

Fellow of the Obstetrical Society.

At the present time, when hospitals may be considered in some measure to be put upon their trial, on account of the attack made on them by an eminent member of our profession—now no longer amongst us—it behoves all who wish to see truth prevail, and the question whether hospitals are an evil or a blessing honestly and correctly solved, to bring forward all the facts and statistics which can legitimately bear upon this subject, and throw them into the common stock, so that a sufficient number of statistics of home-practice may exist to make a comparison with the large numbers treated in hospitals anything like fair.

It is not in a spirit of partisanship for either side of the controversy that I am induced to contribute my mite towards amassing a sufficient number of figures to bear the comparison, but solely with a view to assist in elucidating the truth; and I trust that many obstetricians may be induced to do the same, so that the records of home-practice may collectively be as large as those of the great lying-in hospitals.

Dr. Matthews Duncan, in his recent work *On the Mortality of Child-bed and Maternity Hospitals*, says: "In order that any confidence in the data of home-practice may be expected, the following conditions are necessary.

"1. They must not be derived from memory.

"2. The items should be noted down at the time of their occurrence.

"3. The statistics should yield credible results.

"4. They should be collected with no particular object in view."

I can conscientiously say that my account fulfils all the conditions considered necessary, as I have regularly kept a record of every case (save the first two) that I have attended from my student days until the present time.

I have taken two thousand consecutive cases for two reasons: first, as supplying an even number for comparison; and secondly, because the first series of cases attended are not so complete in all particulars as the later ones. I have also eliminated from this account all those cases in which I had been called in to assist another practitioner, or for consultation. The number of pregnancies is as follows.

First pregnancy ...	403	Tenth pregnancy ...	39
Second pregnancy ...	369	Eleventh pregnancy ...	34
Third pregnancy ...	294	Twelfth pregnancy ...	27
Fourth pregnancy ...	253	Thirteenth pregnancy ...	11
Fifth pregnancy ...	170	Fourteenth pregnancy ...	7
Sixth pregnancy ...	136	Fifteenth pregnancy ...	5
Seventh pregnancy ...	106	Seventeenth pregnancy ...	1
Eighth pregnancy ...	89	Twenty-second pregnancy ...	1
Ninth pregnancy ...	55		

*Sex of Children.*—The 2000 labours produced 2018 children—1014 males, 1003 females, and 1 of no sex. Of these 131, or 1 in 15.41, were still-born; viz., 79 males, 51 females, and 1 of no sex.

The Presentations were—

Of the face ...	5, or 1 in 400
Of the brow ...	5, or 1 in 400
Of the arm ...	8, or 1 in 250
Of the foot or feet ...	25, or 1 in 80
Of the knee ...	1, or 1 in 2000
Of the breech ...	30, or 1 in 66.66
Of the shoulder ...	2, or 1 in 1000

The remaining 1943 presentations were of the head; but what were the relative proportions of the different positions of the head I am unable to say, as in many of the cases, especially the earlier recorded ones, I did not always endeavour to ascertain; being satisfied if it was the head. Forty-four were born with the face to the pubes.

Of the ten face- and brow-presentations, three were with male children and seven with female. One male and one female were still-born; the other eight were living.

Of the eight arm-presentations, five were with female children and three with male; two males and one female were still-born.

Of the twenty-five footling cases, fifteen were males and ten females. Thirteen males and four females were still-born; five of the living children were of twin cases. Seventeen out of twenty-five seems at first sight a great mortality; but nine of these cases were premature, and the children had been dead from two to three weeks. One case was complicated with ascites, and the abdomen had to be punctured before delivery could be effected; one was complicated with serious hæmorrhage from partial separation of the placenta implanted near the os uteri; in one the mother had a distorted pelvis. These being fair cases for elimination, the mortality is reduced much below 1 in 2½, the proportion given by Churchill.

Of the breech-presentations, fourteen were males and sixteen females—nineteen living and eleven still-born. Of these, four were premature. Nine of the cases were first labours. The mortality in British practice, according to Churchill, is about 1 in 2.6; the mortality in these thirty cases is little less; and, excluding the premature cases, is only 1 in 4.25 nearly. The average duration of labour was 11½ hours.

The Twin-cases were 19 in number, or 1 in 105.26. Of these—

4 occurred in the first pregnancy.	2 occurred in the sixth pregnancy.
5 " second "	1 " seventh "
1 " third "	1 " eighth "
2 " fourth "	1 " ninth "
2 " fifth "	

Of the thirty-eight children, thirty were born alive—fourteen males and sixteen females; of the eight still-born, seven were male and one female. In eight cases, the heads of both children presented; in one, the head and arm; in two, the head and breech; in six, the head and feet; in one, the feet in both. In one case the ovum came away entire, the membranes being unbroken, and containing the fœtus and liquor amnii. This was a premature case.

*Forceps Cases.*—The cases delivered with the assistance of the forceps were fifty in number, or 1 in 40.

32 occurred in the first pregnancy.	1 occurred in the sixth pregnancy.
6 " second "	1 " seventh "
3 " third "	2 " eighth "
1 " fourth "	2 " ninth "
2 " fifth "	

Thirty-one of the children were males and nineteen females; six were still-born. The causes necessitating the use of the forceps were powerless labours, small pelvis, and presentations in the third position—the head not making the turn in the pelvis. Version was had recourse to in thirty-two cases, or 1 in 62.5. This proportion of version cases approaches nearer to the German statistics of the operation, 1 in 63½, than the English, the latter being 1 in 259½. It was performed—

For presentation of the shoulder in.....	2 cases.
For presentation of the arm in.....	8 cases.
For presentation of the face in.....	5 cases.
For presentation of the placenta in.....	3 cases.
For presentation of the head in .....	14 cases.

In one case of presentation of the head in which version was performed, the mother had been delivered in her previous labour by craniotomy; in the others there was disproportion between the size of the pelvis and the foetal head; and I might have been induced to perform craniotomy in several of them, had I not felt convinced of turning being a ready and sufficient remedy. As it is, I have never had a case of craniotomy in my own practice. All the mothers recovered and did well. Excluding the two premature children, the mortality to the children in these cases was 1 in 2.90, or a little less than 1 in 3, the proportion given by Churchill; but as some of these cases represent others in which craniotomy might have been performed, I consider the results of these version cases as very satisfactory.

Hæmorrhage occurred in 68 cases, or 1 in 29.39. Of these, 25 were cases of accidental, 3 of unavoidable, and 40 of *post partum*, hæmorrhage. The accidental cases were 25, or 1 in 80. Of these—

None occurred in the first pregnancy.

5	"	"	second	"	.....	or 1 in 73.8
3	"	"	third	"	.....	or 1 in 98
3	"	"	fourth	"	.....	or 1 in 84.33
2	"	"	fifth	"	.....	or 1 in 85
2	"	"	sixth	"	.....	or 1 in 68
2	"	"	seventh	"	.....	or 1 in 53
1	"	"	eighth	"	.....	or 1 in 89
2	"	"	ninth	"	.....	or 1 in 27.5
3	"	"	tenth	"	.....	or 1 in 13
1	"	"	eleventh	"	.....	or 1 in 34
1	"	"	twelfth	"	.....	or 1 in 27

In these cases three mothers were lost, two of which were cases of concealed accidental hæmorrhage. In one, the mother had a fall two months before, followed by hæmorrhage, which recurred in a month; she lived thirty-one hours after labour commenced, giving birth to a living child. In the other case the child was still-born; the mother lived for eighteen days in a state of peculiar nervous excitability, and died of pneumonia after two days.

Of the three cases of unavoidable hæmorrhage, or 1 in 666.66—one occurred in the fourth pregnancy, one in the eighth, and one in the twelfth. The mothers all survived; two of the children were lost.

Of the 40 cases of *post partum* hæmorrhage, or 1 in 50—

14	occurred in the first pregnancy.....	or 1 in 28.57
4	" " second " .....	or 1 in 95.26
5	" " third " .....	or 1 in 58.8
5	" " fifth " .....	or 1 in 34
2	" " sixth " .....	or 1 in 68
3	" " eighth " .....	or 1 in 29.66
2	" " ninth " .....	or 1 in 27.5
1	" " eleventh " .....	or 1 in 34
1	" " twelfth " .....	or 1 in 27
1	" " thirteenth " .....	or 1 in 11
1	" " seventeenth " .....	or 1 in 1

Although several of the mothers were in a very precarious state, I am grateful to say I did not lose one.

Retention of the Placenta occurred in twenty-three cases, or 1 in 86.95. No mothers were lost. Five were cases of hour-glass contraction; in sixteen of the cases the hand was introduced into the uterus to extract it; in four cases there was what is called morbid adhesion.

Protrusion of the Funis occurred in nine cases, or 1 in 222.2; once with presentation of the feet; in the other eight cases before the head. This, one of the most fatal of the complications of labour, was especially so in my cases; only one of the children being saved, although in three of the cases the cord was replaced.

Convulsions complicated labour in seven cases. Five of these were in primipare; in three the convulsions occurred after labour, and were slight; one patient was the subject of periodical epileptic attacks; one case was rapid and severe, the woman dying undelivered soon after I entered the room, and before anything could be done. With this exception they all recovered. Five of the children were born alive.

Retraction of the Uterus occurred in two cases, at about the third

month. The uteri had to be replaced three or four times. They both ultimately went the full term.

Labour was induced prematurely in six cases. In three, the membranes were detached from the uterine wall by the sound; in two the douche was used after Kiwisch's plan, and in one Barnes's dilators were used. The results are shown in the following table.

No.	Age.	No. of Preg.	Means used.	Duration of labour.	Sex of child.	Living or not.
1	23	4	Sound.	8½	Male.	Living.
2	28	5	Sound.	48	Female.	Living.
3	23	3	Sound.	12	Female.	Living.
4	39	4	Douche.	11	Female.	Living.
5	28	3	Douche.	3	Male.	Living.
6	26	3	Barnes's bags.	46	Female.	Dead.

In the sixth case the labour was very lingering, and the child died in consequence of its being protracted for nearly two days with occasional long periods of freedom from pains, and not from any defect in the means used to bring on labour, as the dilators acted well and efficiently—indeed, they always have done so whenever I have used them, as I have frequently done since in consultation-cases, and I consider them the most certain and effectual of our armamenta for this purpose.

Premature Labour occurred 71 times, or 1 in 28.16 cases.

At six months ... .. in 8 cases.

At seven months ... .. in 29 cases.

At eight months ... .. in 34 cases.

Five of the cases were plural births: 45 children were living and 31 dead. In four cases the head presented in the third position, in one the arm, in five the breech, and five the feet.

Illness after delivery occurred in 34 cases.

From puerperal fever ... .. 5	From phlebitis in left leg ... .. 1
" peritonitis ... .. 7	" retroversion of uterus ... .. 1
" pyæmia ... .. 1	" pneumonia ... .. 2
" febricula ... .. 2	" bronchitis ... .. 1
" variola ... .. 2	" spasmodic asthma ... .. 1
" diarrhoea ... .. 2	" hæmoptysis ... .. 1
" pelvic cellulitis ... .. 2	" jaundice ... .. 1
" phlegmasia dolens ... .. 3	

These include only the severe disorders: slight febrile attacks, such as occur on the advent of the lacteal secretion, or from a loaded state of the bowels, quickly relieved by their evacuation, or other transient states, are omitted.

Death occurred in 16 cases, or 1 in 125.

From puerperal fever ... .. 2	From accidental hæmorrhage ... .. 1
" peritonitis ... .. 3	" concealed accidental hæmorrhage ... .. 2
" pyæmia ... .. 1	" spasmodic asthma ... .. 1
" diarrhoea ... .. 1	" bronchitis ... .. 1
" exhaustion—syncope ... .. 2	" pneumonia ... .. 1
" eclampsia ... .. 1	

Puerperal Fever.—Case I, aged 39; ninth pregnancy; 53 hours in labour; retention of placenta, with hour-glass contraction; death on the fifteenth day.—Case II, aged 36; fourth pregnancy; 9½ hours in labour; subject to acute rheumatism; died on the eleventh day.

Peritonitis.—Case I, aged 26; second pregnancy; quick labour; retention of placenta; death on the eleventh day.—Case II, aged 19; second pregnancy. This woman recovered well from her labour, and went out early, but was seized on the twenty-fourth day, and died on the 27th.—Case III, aged 21; first pregnancy; forceps-case; died on the tenth day, with coexistent erysipelas of the leg, and she had been in hospital twelve months before with erysipelas of the same leg and thigh.

Pyæmia.—Aged 24; second pregnancy; death on the eleventh day, with effusion into all the serous cavities. The patient had a puerperal attack after her first labour.

Diarrhoea.—Aged 30; third pregnancy. Diarrhoea commenced five days before labour, and continued until the second day, after which she died. She had diarrhoea two weeks before the birth of the second child.

Exhaustion.—Case I, aged 25; first pregnancy; forceps-case; dead child; died in half-an-hour (granular kidney).—Case II, aged 30; first pregnancy; face-presentation; twenty-six hours in labour; death in forty minutes from syncope.

Eclampsia.—Aged 35; first pregnancy. A case of severe apoplectic eclampsia; she died undelivered soon after I entered the room.

Accidental Hæmorrhage.—Aged 44; eleventh pregnancy. She had a fall a week before, and the same morning placed her feet in hot water,

soon after which she had a fearful gush of hæmorrhage. She was put into bed and plugged. She was delivered of a still-born child after four hours; but she never rallied, dying in two hours afterwards, having had no more hæmorrhage.

*Concealed Accidental Hæmorrhage.*—Case I, aged 38; ninth pregnancy; had a fall two months before, which brought on hæmorrhage, from which with care she recovered, and went on to the full term. The child was born after six hours' labour, and she died in twenty-seven hours from syncope.—Case II, aged 28; fourth pregnancy; was seized with faintness and vomiting; feeble pulse and great prostration; she was well bound up and supported with stimulants until pains came on; after the expulsion of the child a large mass of clots followed. She was very feeble and suffered from intense nervous excitability for eighteen days, when she died after two days' pneumonia.

*Spasmodic Asthma.*—Aged 37; tenth pregnancy; was thrown out of a trap at about the sixth month, which shook her much, and from which she had slight concussion. The attack of asthma came on three days before labour; she had albuminous urine; died on the eleventh day.

*Bronchitis.*—Aged 34; premature labour on account of the bronchitis; she died in two days.

*Pneumonia.*—Aged 43; thirteenth pregnancy. This woman got out of bed on the night of the fourth day after delivery, and, without shoes or stockings, or any covering other than her night-dress, traversed a landing to the rooms of her children to see if they were safe. She was seized with pneumonia, and died on the ninth day.

Although the proportion of deaths has been 1 in 125, it is singular that I attended 250 labours before meeting with a fatal case; and, as if to prove to me the fallacy of calculating statistically from a small number of data, I found the next three deaths to occur in a much more rapid sequence—1 in 66, 3—although I subsequently had an interval, in which 451 cases were attended without meeting with a death. I should also add that, after attending the first fatal case of puerperal fever, in which I made a *post mortem* examination, I delegated my midwifery cases to a brother practitioner for the space of one month; and whenever I possibly could, which was nearly always, I got cases of erysipelas attended by proxy also.

The ages of the patients and the duration of labour have been omitted from this account, as in many of the cases reliable information could not be satisfactorily obtained, whilst some facts and data relating to the duration of pregnancy I have reserved for a future occasion.

## CHLOROFORM ACCIDENTS.

By J. T. CLOVER, F.R.C.S.

THE attention of medical men has been recently called to this subject, by a revision of Professor Lister's article on anæsthetics in Holme's *System of Surgery*. If I understand Mr. Lister, he maintains—1. That in deaths from chloroform the breathing fails before the circulation; 2. That the chief danger arises from laryngeal obstruction; 3. That the chief duty of the administrator is to watch for laryngeal obstruction, and draw out the tongue with forceps when it occurs; 4. That it is useless to watch the pulse; 5. That chloroform may be given as safely by means of a towel as by any apparatus. My experience obliges me to differ from Mr. Lister on these points. I have administered chloroform more than seven thousand times, and ether, tetrachloride of carbon, ethylenedichlorid, the compound "bichloride of methylene", and nitrous oxide, in four thousand other cases. I have never drawn out the tongue, and never lost a patient from any anæsthetic. My aim has always been to give the anæsthetic equally mixed, and in the smallest proportion needed for the purpose, so that, if the effect became greater than I wanted, there might be as little of the agent as possible in the chest requiring to be got rid of.

For several years I gave chloroform upon lint held at a distance from the face, but covered over with a towel; but I found it impossible always to prevent the patient from inhaling more than I desired. This induced me to contrive an apparatus which I exhibited in 1862, and have used constantly since. It enables me to administer the vapour of three minims and a quarter of chloroform with every one hundred cubic inches of air. This proportion rarely excites coughing or swallowing; and whenever any laryngeal obstruction has been threatened I have prevented it by raising the chin, and never have been obliged to draw out the tongue.

It is my habit when giving anæsthetics to watch the pulse as well as the breathing, and I am, therefore, better able to speak of the effect of chloroform upon the heart than those who disregard the pulse. It appears that in Mr. Lister's practice the necessity for dragging forward the tongue is of frequent occurrence. Either his method of giving chloro-

reform is not the best that may be devised for preventing the choking, or else the severe process of seizing the tongue with artery-forceps when the choking occurs is not so imperative as he supposes. Probably some of his patients were so affected by the pungency of the vapour that the simpler expedient of raising the chin well away from the sternum, which I have never found to fail, might have been sufficient.

There is an obstruction to breathing from closure of the glottis of a reflex character. It is often produced when a ligature is applied to a hæmorrhoid or to the pedicle of an ovarian tumour; but the obstruction Mr. Lister dwells upon, I suspect, nothing more than an *act of swallowing imperfectly performed*. Every one must have noticed that swallowing is very commonly excited by the vapour of chloroform when first inhaled, and the stronger the vapour, the more frequent and annoying to the patient it becomes. There is reason to think that, under chloroform, the co-ordination of the movements which constitute deglutition is interfered with, and that in consequence it lingers in the second stage, when, as we know, there is normally a stoppage to the passage of air.

It is a remarkable fact that we do not get the laryngeal stoppage from nitrous oxide, although it produces a very deep stertor. In some thousands of cases I have continued to give the gas until this stertor was produced, but I do not remember a single case where the larynx was completely stopped. It is probable that the immunity from this accident depends upon the circumstance that the gas is so bland that it never stimulates the throat enough to produce the act of swallowing.

In giving chloroform I have met with several cases of partial obstruction of the larynx, where the mere depressing or raising of the chin was enough to close or open the passage. In such cases, if I had tried to open the mouth by pushing down the chin, I should by that very means have caused total obstruction, such as Mr. Lister describes; and then, no doubt, dragging out the tongue would have been followed by a free inspiration, and probably louder and freer than the one produced by the simple process of elevating the chin.

I am convinced that the chief cause of danger is the effect of chloroform upon the heart. Several deaths have occurred where failure of the pulse was noticed before the breathing became difficult; these cases should have recovered if Mr. Lister's theory be correct. Supposing the larynx to be obstructed at a time when the heart is acting well, and when not more than four or five per cent. of chloroform vapour is in the chest, the narcotism will diminish for the following reason. The blood circulating through the general system deposits a part of the chloroform in the tissues, and, passing through the lungs, it soon reduces the proportion of chloroform there present, and is no longer supplied with a sufficient quantity to keep the nervous centres under its full influence.

Those who have had experience in giving chloroform in a manner to secure that the air breathed only contains four per cent., must have noticed that patients who strain and hold their breath for half a minute or more, as they fell into a state of insensibility, are less under the influence of the anæsthetic when they recommence breathing than when they began to hold their breath. Supposing, however, that the lungs contained ten or twelve per cent. of chloroform, a very different result would occur; the narcotism would increase, for the heart's action would first be diminished, and as a consequence of this the blood would pass through the lungs more slowly, and by passing more slowly would have time to take up still more of the chloroform, and have a dangerous or fatal effect upon the ganglia of the heart. This is the worst form of accident that can happen; for it is obvious that, without effective circulation through the lungs, drawing out the tongue and artificial respiration would be useless.

The pulse varies considerably under the influence of chloroform; it often fails and is scarcely perceptible when sickness is about to take place; also when extensive incisions are made, or important nerves are injured. Whenever chloroform is given stronger than four and a half per cent., the pulse loses force rapidly. Experiments with the hæmadynamometer show that the arterial pressure diminishes when animals are kept under the influence of chloroform. If chloroform vapour is administered very strongly through a trachea-tube, it stops all action of the heart in sixteen seconds. It cannot be too strongly impressed on those who administer chloroform that the same proportion which would be safe when the blood passes quickly through the lungs, might be dangerous if the blood moved slowly, because in the latter case it would take up more chloroform.

I will mention a single case out of many which tend to show both that the pulse must be watched, and that no higher proportion of the anæsthetic should be given than is absolutely needful. A gentleman, fifty years of age, was inhaling chloroform freely, when, finding that his pulse became unsteady and soft, I discontinued the chloroform whilst he was still breathing satisfactorily. I felt the pulse become less and less, and in a few seconds cease; as he continued to breathe freely

and was recumbent, I merely waited, hoping that the pulse would return; and I saw his respirations gradually become fainter and at longer intervals, till at the end of a minute or so they also ceased, and he seemed dead. I now kept up the movements of the chest artificially for about a minute, when he breathed again spontaneously, and his pulse returned. In a few minutes he entirely recovered. It was the pulse which gave me the first warning of danger. Although I withdrew the chloroform whilst he was still breathing, he had a narrow escape, and I cannot avoid the conclusion that had he inhaled chloroform air instead of pure air, during the minute which followed the stopping of his pulse, he must have died.

## ON THE CONTAGION OF SCARLATINA AND SMALL-POX.

By T. T. PYLE, M.D.,

Physician to the Sunderland Infirmary, etc.

AT the present moment, when the public mind is agitated by doubts as to the necessity for vaccination on the one side, and by the fear of catching small-pox on the other, it may not be amiss to bring forward a few simple facts illustrative of the manner in which contagious diseases are spread abroad, and indicative of the means by which they may be prevented by timely care and attention. I maintain that it is by the neglect of a few very simple rules that our population is decimated by these infectious diseases; and we shall never check their progress until medical attendants and the heads of families are careful in carrying out a system of isolation on the appearance of fever in their villages or in their houses, and also in carefully tracing the virus-bearer so as to catch and imprison him until he is thoroughly disinfected and has ceased to be a pest to society. For these reasons, I call attention to this important subject, and venture to relate the following cases which have come under my observation in my own family and practice.

I shall begin by a case of scarlet fever that took place in my own house in the latter part of 1870. My eldest child, Ethel, aged 8 years, went to play with her little cousins for two days consecutively, and, on the evening of the second day, she awoke from her sleep with violent vomiting, and complained of pain in her throat. Two days after this, the eruption of scarlatina appeared. She had a rather severe attack; but, I am thankful to say, passed through the disease without any very formidable symptoms. It appeared that the housemaid at her cousins' house, about a week or so before, had suffered from sore-throat and excessive vomiting and prostration: she had been confined to bed for a couple of days, but was afterwards able to go about the house and perform her duties, though extremely weak. I made every inquiry where the child could have caught the infection. I had myself not attended any case of scarlatina for several months before that period. The laundress had not washed any clothes except for our family and the family of a patient of my own, whose children were quite healthy; and the only conclusion that could be arrived at was, that this housemaid had had a slight attack of scarlatina, and gave it to my little girl, who, perhaps, was rather in a condition to receive it, having just been convalescent from an attack of bronchitis.

The second case I can trace very clearly. Miss M., a governess from a school in Sheffield, came to Sunderland for the Christmas holidays, and consulted me for a chest-affection. On her next visit to me, about ten days afterwards, she was very depressed, and gave the following reason. Before leaving the school at Sheffield, a favourite pupil took scarlet fever; she nursed the child throughout its illness till its death. A few days after her return home, she wore the same dress that she had while she attended on her pupil. One of her little brothers took scarlet fever, and died within a few days. Three or four of the other children in the house also took the disease, but she herself never had the least symptom of it.

The third case occurred at a colliery village some few miles from this town, and one over which I have the medical supervision. The resident medical gentleman informed me that there had not been a case of scarlatina in the place for more than a year before. The village contains somewhere between three and four thousand inhabitants. When I was first called to see the child, the rash of scarlet fever was well developed, and the parents could give me no idea how the disease could have been caught. The drainage was excellent, the children were well fed, and the air good, being on the sea-coast. This child ran through the course of the disease in a mild form, and recovered. By very careful inquiry, I discovered that a relative of the parents had sat up all night in Sunderland a few days before this period, nursing a neighbour's child that had been ill and delirious, but, as they stated, merely with a very bad sore throat. Before leaving this case, I ought to state that I took every

precaution to prevent the spreading of the disease in the village. In spite of my efforts, some of the friends visited the house, and the fever appeared in two other houses in the place, in one of which three cases of scarlatina occurred, and in the other house one case. By impressing on these people the great importance of preventing any communication whatever with their friends, I was gratified to find that my instructions were fully carried out; and no other cases broke out except in the house where the first case was discovered. A brother of the child first affected was not at home when the fever appeared, and I ordered that he should be kept away for some time. After seven weeks, and when the child affected had become convalescent, the other child was brought home. I could not clearly ascertain if it had worn any of the clothing of the affected child; but, a few days after its return, it had a mild but distinctive attack of scarlet fever. I am happy to state that since that time, now several weeks ago, no fresh case of scarlatina has occurred in the village.

The following case will illustrate the direct contagion of small-pox, which is now occupying so much attention. It occurred at the same colliery village, and was brought from Hartlepool (a town distant about twenty miles) by a man in the desquamative stage, or, as they expressed it, "red raw", after the disease. He was invited to the house for change of air, and stayed about a week. Two days after he left, one of the children who had never been vaccinated, and whom the man had fondled a great deal and frequently had to play with him, took the confluent form of small-pox. The other children in the house had also not been vaccinated, but the Resident Surgeon and Public Vaccinator for the district at once had them vaccinated. They did not take the disease; and, by a proper surveillance of the house, and preventing any communication with it, no other cases have yet appeared.

## CLINICAL ILLUSTRATIONS OF CUTANEOUS DISEASE.

By ERASMUS WILSON, F.R.S.,

Professor of Dermatology in the Royal College of Surgeons.

*Melasma Frontis, with General Melasma in Patches, originating in Cachexia.*—March 27th, 1871. A robust woman, aged 40, is troubled with a greyish-black stain which covers all that portion of the forehead which is exposed to the light. Her neck is also swarthy, and the integument of the whole body is darkened with pigmentary blotches of irregular figure and extent. This melasmic affection has been two years in progress, and is now somewhat less than it was some months back. Her health has been much shaken by numerous causes of exhaustion. Some years ago, she had a severe attack of rheumatic gout; this was followed by several miscarriages; and, immediately before the darkening of the skin was first observed, she suffered very considerably from abdominal spasm, accompanied with flatulence.

Perverted pigmentation of the skin in the form of melasma may always be traced to causes affecting innervation, assimilation, and sanguification. Such causes existed in the present instance; and the pigment-substance would seem to owe its origin to the destruction of the red corpuscles of the blood, for anaemia, in a greater or less degree, is always present with melasma; and in the present instance the sclerotic was anemically pale.

*Erythema Solare, affecting the Face and Hands on Exposure to the Rays of the Sun.*—April 4th, 1871. Pellagra, the *mal del sole*, a disease of the South of Europe, has made us acquainted with an erythema due to a neuropathic condition of the skin; the disease subsequently invading the whole of the nervous system and brain, and ending in madness. Such a type of disease as this is necessarily recalled to the mind when anything of a similar nature, however remote, is brought under our notice; and it is as a far distant resemblance of the earliest stage of this affection that I now record the following case.

A healthy-looking young woman, aged 38, complains of the scorching effect of the sun upon her face and hands; and, to illustrate her complaint, she shows me the back of her hand, upon which she has allowed the light of an early April sun to impinge while awaiting her turn of consultation, about an hour. Sure enough, the hand presents a well marked erythema of a dull red or purplish-red colour—a slight degree, she observes, of the appearance produced during the warmer months of the year. The inference is evident. Her skin must be unusually and morbidly sensitive to be injured to such an extent by the actinic rays of the sun. She dates back this hypersensitiveness of the skin to a period of seven years; and since that time she has also noticed that her skin is unusually dry and lacking of perspiration.

*Prurigo Mitis, from imperfect Assimilation.*—March 11th, 1871. A

gentleman occupied in office duty from ten until four daily, aged 57, is troubled with pruriginous papules, distributed chiefly over the back of the trunk. The papules are of the kind which are felt rather than seen, and appear to be due to congestion and infiltration of the vascular coat of the follicles. His attention is attracted to the seat of the papules by itching; the finger detects a hardness, which is described as being under the skin; the part is scratched with the nails; and then an angular or square shaped excoriation remains, which dries up into a thin reddish scab. These spots make their appearance from time to time, but never exceed ten or twelve in number. Formerly he suffered from gout, but has had no symptoms of that complaint for four years. The gouty diathesis has for the time being been merged into the dartsous diathesis, and at present manifests itself as a simple prurigo such as I have now described. He was benefited very much by a tonic aperient treatment, and lotion of bitter almonds with hydrocyanic acid; but, not being entirely relieved at the end of a month, and his digestive functions being properly performed, I prescribed three minims of Fowler's solution three times a day, in my ferro-arsenical mixture.

*Elephantiasis Græcorum, the Oriental Leprosy.*—March 15th, 1871. A subaltern officer of the army, aged 43, a tall well built man, is afflicted with elephantiasis in its maculated stage. His face has a deep coppery-red hue; the trunk of the body and limbs are spotted all over with large round blotches an inch and a half to two inches in diameter, the pigmented surface being greater in extent than the sound skin. The blotches on the trunk of the body have a deep red brown hue, darkest in the centre, and fading at the circumference. But on the hips, thighs, and legs, the centre of the dark brown blotches is of a dead white colour, from loss of pigment; and these white areas are more or less completely anæsthetic. The skin has not as yet arrived at the tubercular stage, and probably may remain as an example of the anæsthetic form of the affection. The ulnar side of the forearms and two corresponding fingers are benumbed from partial paralysis of the ulnar nerve. The integument of this region is also deeply pigmented, and interspersed with white areas and a few cicatrices from slight ulceration. The feet, he says, are wholly unaffected. He has no constitutional symptoms of disordered health, with the exception of a burning flush in his face after taking food. He resided in India twenty-four years, and, shortly after his arrival there, had syphilis, followed by secondary symptoms. At different times, his regiment has been quartered in Madras, Bengal, the Malabar coast, and Lucknow. He was at the latter place when the disease first began, two years ago; and at present has returned to England. He has been married fifteen years, and has a family, but is wholly unaware of the nature of his disorder.

## HIGH TEMPERATURE IN VARICELLA

By JAMES RAMSAY, M.A., M.D., York.

BEING called to see Miss M., a young lady, aged 15, living in a boarding school, on May 27th, I found her suffering from a smart attack of chicken-pox. She was confined to bed, feverish, and complaining of slight headache and nausea. On the face, arms, neck, and chest there was a mixed eruption of reddish papules and vesicles in different stages. The fully formed vesicles were about the size of split peas, semi-ovoid, with but slight areolæ, destitute of central depression, and contained perfectly limpid serum; on pricking one or two, they collapsed entirely. There was no eruption on the lips, tongue, or fauces, and no sore-throat. The tongue was coated with thick creamy fur; the appetite was suspended; the bowels confined. The urine was rather scanty and high coloured. The skin was very hot, but moist. The spots were most abundant on the face and neck. They had come out simultaneously over the parts mentioned. Malaise had been felt the day but one preceding my visit, and next morning the first crop of papules had appeared. A fresh crop had come out on the morning of the day of my visit. She had been revaccinated six weeks previously.

Having some doubts about the diagnosis between varicella vera and varioloid, I saw her again about 9 P.M. the same day. There was then little change in the state of the eruption. The pulse was 120 per minute; the temperature very high, being 103.8 deg. Fahr. in the left axilla. The face was considerably flushed. There was no cough or dyspnoea; the state of the chest was normal; and nothing of a local nature could be found in any way to explain the great general disturbance of the system. Next day the patient was better, but the temperature was still high, 100.5 deg. On the following morning it was 99 deg., and the day after it was normal. She continued quite well from that time.

After a careful investigation into the sources of infection, it was discovered that some children in a separate but adjacent house were suffering from chicken-pox; and no doubt infection had been brought thence by one of the servants, who had had intercourse with a domestic in the infected house. From the fact that few of Miss M.'s school-fellows had been revaccinated, I was at first in some doubt as to what course I should adopt with them; for it was some time before I was quite convinced of the nature of the case. I had at one time seriously contemplated the advisability of breaking up the school; but, as there were means of securing complete seclusion, I determined to wait. Any one who has been familiar with the perplexing appearances of modified small-pox, and the possibility of an outbreak of it in a house full of young ladies being taken into account, will quite understand the difficulty of my situation. The point which I venture to think of greatest interest, and which afforded me most anxiety, was the high range of temperature observed on the evening of the third day of the disease. Authors are, I think, hardly explicit enough, as a rule, in alluding to this point. Heberden, writing in 1802, even denies the presence of "fever" in varicella. Gregory, too (1843), calls it always "slight." Dr. Gee, in Reynolds's *System of Medicine*, speaks of it as being "mild." Aitken (*Practice of Physic*, vol. i) observes that "the fever may be severe for a few hours, but perhaps it never passes into a stage so severe as to have the tongue of a brown or coated appearance." Dr. Austin Flint, whose work on *Medicine* is most valuable as an exposition of observed clinical facts, describes it as "slight or wanting." Dr. West (*Diseases of Children*) writes that the fever is scarcely ever severe—sometimes altogether wanting. He has, however, sometimes seen children (who were teething actively at the time) suffer for twenty-four or thirty-six hours from febrile symptoms, quite as severe as those preceding the eruption of measles. Trousseau states that there are outbursts of fever, sometimes violent, for four or five nights, ceasing by day. The great mass of cases, of course, are attended with little general disturbance; but the one which I have described, though exceptional, shows us that even in a well grown subject, otherwise in perfect health up to the date of the attack, the temperature may be for a time sufficiently high to cause much hesitation in forming a diagnosis from varioloid, to which varicella frequently in other points bears a marked resemblance. The knowledge of the possibility of such a condition may be of service, and might prevent such an unfortunate mishap as the needless breaking up of a school; and I hope this consideration will be held to excuse the present notice of the subject.

I may add that the sister of Miss M. exhibited the appearances of varicella exactly fourteen days after the strict seclusion of the latter had been put in force. She went through a similar course without, however, any marked febrile symptoms.

## CLINICAL MEMORANDA.

### ATROPHY OF THE TONGUE.

HYPERTROPHY of the tongue is occasionally met with, and an interesting case of this kind, affecting only one-half of the organ, has been related by Dr. Graves (*Dub. Hos. Rep.*, iv, 43); but we have it on the authority of Mr. Holmes Coote (in Holmes's *System of Surgery*) that there is no well-authenticated instance of atrophy upon record. A case lately came under my notice which appeared to be one of unilateral atrophy of the tongue, but I hesitate to publish it, because the history is imperfect and no *post mortem* examination was allowed. It has led me, however, to search for other examples of a like kind, and my search only confirms Mr. Holmes Coote's statement with regard to the extreme rarity of this disease. I should be glad, therefore, to ask whether any of the readers of the JOURNAL have ever seen atrophy of the tongue, or can direct me to the history of such a case in medical literature.

Curzon Street, Mayfair, July 3rd, 1871. W. FAIRLIE CLARKE.

### RARE LUXATION OF THE ANKLE-JOINT.

I HAVE read with interest in the JOURNAL of the 13th May the report of a case of "rare luxation of the ankle-joint" by Dr. Eames. About a year ago, I met with a case of similar injury.

Miss L., a stout middle-aged lady, while descending a hill suddenly slipped her foot, or, as she better expressed it, "went on the outside of her foot". She fell, and was quite unable to rise. On seeing her after she was carried home in about half-an-hour afterwards, I found the foot displaced inwards; the plantar aspect pointed to the middle line of the body, the external edge looking downwards; there was very great prominence of the external malleolus. Reduction was very easily effected.

Most careful examination was also made of both malleoli, with the result of finding neither fractured. The limb was put up in splints to maintain perfect rest of the joint. In a few weeks the joint had regained its normal state, all its movements being quite unimpaired.

Barnstisland.

JAS. CARMICHAEL, M.D.

## THERAPEUTIC MEMORANDA.

### HYDRATE OF CHLORAL IN DELIRIUM TREMENS.

THE gate-porter of the London Fever Hospital was taken with vomiting and diarrhoea between 12 and 1 A.M. of May 31st; he had also headache, pain in the loins, and tremor. At 1 P.M. his temperature was 99 deg.; at 5 P.M. 102 deg. An emetic of ipecacuanha was given, and at 10 P.M. the temperature was 100.8 deg. He had perspired freely after the emetic, as well as vomited.

He did not sleep much on the night of the 31st May or of June 1st, though he took a dose of opium each evening. On June 2nd he felt and looked much better; the bowels were still loose, and he had slight headache; the tongue was covered with a pale thin fur. Temperature from the morning of June 1st, very nearly normal.

On the evening of the 2nd he began to have hallucinations and marked tremors, and he had no sleep during the night, notwithstanding repeated doses of laudanum.

Throughout the 3rd he was violently excited by all sorts of fancies. Towards evening he shouted "Police", "Murder", and could scarcely be kept in bed. There was much tremor of the limbs and tongue; the skin was cool and clammy; pulse 120, soft; tongue moist; bowels open; pupils small. He seemed exhausted, and his expression was haggard. He had remained much in the same condition, and was equally delirious, but less violent, because weaker, when I saw him about 4.30 P.M. on the 4th June for the first time after the accession of the delirium. He had had frequent and large doses of Battley's solution of opium, but had not slept at all, and seemed as wakeful and as restless as ever. I ordered him to have an ounce of brandy in a cup of beef-tea immediately; this to be followed in a quarter of an hour by forty grains of chloral. Ten minutes after taking the chloral he suddenly fell asleep, and continued to sleep calmly, opening his eyes two or three times and taking milk or beef-tea, till 9.30 P.M., when he awoke and had still slight delirium and tremor. Twenty grains of chloral were again given, and for the next thirty-six hours he slept continuously, waking only to take food, and going off to sleep again at once. At the end of this time he was quite well.

June 29th, 1871.

St. Mary's Hospitals.

### LOCAL APPLICATIONS AND CHLORAL IN SMALL-POX.

A VERY useful local application, which I have used extensively in the treatment of small-pox, consists of a mixture of liquor calcis saccharatus (P. B.) with linseed oil, in the proportion of two and a half ounces of the former to two ounces of the latter. This combination seems to me to be an improvement on the old Carron oil. It is of the consistence of "salad cream," and is very soothing when applied to the skin in small-pox, and it relieves the tendency to scratch the pustules. No doubt the sugar increases the mollifying influence of the oil and lime.

There is, perhaps, no medicine for which small-pox patients are more grateful than for an occasional dose of hydrate of chloral. During the first few days of the disease, want of sleep is very generally present, and causes much distress. A moderate dose of chloral at bedtime will ensure several hours of deep and refreshing sleep. While on the subject of chloral, I may refer to an application of the drug which I have not seen adverted to elsewhere, but which I have found of considerable use in my own person. Probably most of those who are accustomed to burn the midnight oil in intellectual work, know that if their studies are kept up beyond a certain time, a peculiar irritability of brain comes on which entirely prevents sleep. The student feels that he could go on working for hours longer; but, if consideration for next day's duties induce him to retire to bed, he finds it impossible to go to sleep, and he tosses about for two or three hours before at length sleep overtakes him. If, instead of waiting all this time while the cerebral irritability gradually subsides, twenty or thirty grains of the hydrate are taken, he sinks within a few minutes into a profound and invigorating sleep; and no unpleasant effects are perceived the next day as the result of using the drug.

FREDERICK POLLARD, M.B. Lond., Resident Medical Officer to the St. Pancras and Northern Dispensary.

OF

## MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS OF GREAT BRITAIN.

### NOTES ON THE TREATMENT OF GANGLION IN THE LONDON HOSPITALS.

[Continued from page 10 of last volume.]

#### MIDDLESEX HOSPITAL.

MR. CAMPBELL DE MORGAN prefers to leave slight cases of ganglion alone. If troublesome on the back of the wrist, he fairly cuts through them subcutaneously, and keeps on pressure. The large ones on the palm of the hand, if he interferes at all, Mr. De Morgan lays open fully, saving the annular ligament; and dresses with some balsamic tincture. Enlargements of the bursa patellæ he treats with rest and iodine. If they be inflamed and suppurating, he lays them open. When they are indolent, he uses puncture and rest; sometimes setons, though Mr. De Morgan states that he has seen mischief from these. He has seen great good from blistering. Ganglia in the popliteal space he never touches, if he can help it. If it be necessary to interfere, the greatest care should be taken to preserve rest. Inflammation is often propagated to the joint from them.

MR. NUNN treats ganglion in the following manner. Ganglion—that is to say, circumscribed inflammation of synovial tissue in juxtaposition with the sheaths of the tendons, forming a tense roundish tumour, more or less moveable—if not capable of being disposed either by steady pressure or by sudden force, rupturing the sac and extravasating the contained fluid into the surrounding cellular tissue, cannot be treated off hand, like an abscess or a boil, by puncture, without considerable risk of diffused inflammation involving the sheaths of the tendons and inter-muscular cellular tissue. As ganglion is frequently caused by excessive movement of the tendons in their sheaths—as in persons training for professional pianoforte-playing—it is difficult to imagine that ganglia are so completely independent of the synovial structure lining the proper sheaths of the tendons as is generally accepted. One might suppose that a pouch could be commenced by a slight effusion of fluid in the sheath, distending the delicate true synovial membrane through a gap in the investing firmer tissue, and that this pouch could become a cyst, as in well-known parallel examples, by obliteration of neck of sac. The fact is (as far as Mr. Nunn's experience goes) that the ganglion is usually, if not invariably, found on the back of the hand. Where the sheaths of the tendons are undefined and apertures common, Mr. Nunn understands that circumscribed effusions *within* the sheaths of flexors or extensors should not be included in the term ganglion, although in many cases, doubtless, essentially of the same nature. These swellings are, on the other hand, sometimes also due to constitutional causes. Subcutaneous puncture, or rather incision, is, in cases not to be ruptured by blow or pressure, probably the best next step, but may require repetition, and should not be done without using a splint as a precaution. The subcutaneous puncture is probably quite as safe as severe counterirritation—a plan which Mr. Nunn has seen tried. But, before using even subcutaneous puncture, he would advise diligent trial of alternate douches of very hot and cold water: this will remove almost with certainty any tenderness along the course of the tendons, and diminish the ganglion if it will not get rid of it. Mr. Nunn has never met with results at all satisfactory from the employment of blister, or of localised pressure by pad and strap.

The mode of treatment which Mr. GEORGE LAWSON adopts for the small ganglia on the extensor tendons of the wrist is, first, to try if he can rupture them by firm pressure with his two thumbs whilst the hand is laid upon the table; and then, by steady rotatory rubbing, to cause the contents of the cyst to be extravasated into the adjacent cellular tissue. He then paints the part with a strong solution of iodine, and applies a firm pad and a bandage. When, however, the ganglion resists the pressure of the thumbs, and cannot in this way be ruptured, Mr. Lawson introduces a tenotomy knife through the skin, at a short distance from the ganglion, and lays it freely open subcutaneously, and then, by pressure with the fingers, evacuates its contents into the surrounding tissues. The parts are then painted with iodine, and a pad and bandage applied as above stated. Mr. Lawson strongly deprecates the plan of using setons for the cure of ganglia, as on two occasions he has seen the hand nearly lost from diffuse cellulitis which followed this mode of treatment.

## ST. GEORGE'S HOSPITAL.

Mr. HENRY LEE's plan of treating ganglia is to puncture them subcutaneously, and to press out their contents into the subcutaneous cellular tissue every day or two until it ceases to reaccumulate. Mr. Lee lately treated in this way, with success, a ganglion as large as a French walnut, on the instep, of many years' duration.

Mr. ROUSE bursts the cyst, when recent, with his thumbs, and well rubs the surfaces together; and in many instances this succeeds. When ganglia are of long standing, he punctures them, squeezes out their contents, then rubs the surfaces, and subsequently blisters or uses liniment of iodine. If this fail, he again punctures, blisters, and dresses the sore with blue ointment. This last generally succeeds, especially if the sac be thick. In those rare cases in which melon-seed bodies exist, which are usually found on the anterior surface of the wrist, Mr. Rouse believes that no treatment save laying open the sac and dressing it in is of any avail. He has had no experience in dissecting out the sac, or laying it open and dressing in with lint, in the ordinary forms of ganglion.

## LONDON HOSPITAL.

Mr. WALTER RIVINGTON invariably punctures the swelling with a fine-pointed bistoury, squeezes out the fluid thoroughly, and then applies a compress tightly for a few days. Failure to cure is in his experience rare.

## ST. MARY'S HOSPITAL.

Mr. GASCOYEN restricts the use of the term *ganglion* to a swelling which is connected with the sheath of the extensor tendons on the back of the wrist and on the dorsum of the foot. He does not regard this as an independent growth, but as a protrusion or hernia of the synovial membrane through the fibrous sheath of the tendon; and considers that its enlargement is produced by the gradual escape of the synovia into it during the movements of the tendon. Mr. Gascoyen therefore advocates a subcutaneous method of treatment, and adopts the old plan of rupturing these swellings by pressure with the thumbs or by a smart blow, afterwards applying a conical pad with a bandage. This treatment he has generally found to effect a cure in recent cases. In those of old standing, when the above means fail to disperse the tumour, he recommends free incision with a tenotomy-knife, introduced in a valvular manner through the skin; and the application of firm pressure in the same manner after evacuating the contents. When these tumours have existed for a long time, they have, however, a great tendency to re-form after any plan of treatment. Blisters, iodine, and other stimulant or absorbent applications, have seldom proved of service; they merely diminish for a time the size of the swelling. The very severe inflammation which often follows the use of setons in these cases renders their employment undesirable. Mr. Gascoyen deprecates excision of these swellings, except in those few instances where the tumour, having become solid, is disposed to ulcerate from friction or some other cause. In these cases, though the connexion between the ganglion and the sheath of the tendon has become severed, so long as the contents remain fluid, showing that there is a communication with the interior of the sheath, he is strongly opposed to any attempt to remove them.

## CHARING CROSS HOSPITAL.

The treatment of ganglion which Mr. HANCOCK has found most successful, and which he now always adopts, is subcutaneous section—making, as far as possible, a crucial incision; and afterwards gradual compression, with rest of the part.

Mr. BELLAMY has found that, in the case of the ordinary non-inflamed ganglia generally met with about the dorsum of the wrist or foot, a good smart squeeze with the thumbs, one on the top of the other, is sufficient to disperse the contents of the sac into the surrounding tissues. This, however, appears to be effective only in ganglia having very thin walls, and situated either above or beyond that point where the annular ligament is thickest, or exists merely as fascia. In ganglia that have existed for some time, where the walls are thick and the cyst frequently multilocular, a puncture should be made, but in a peculiar way. A sharp-pointed tenotomy-knife should be introduced flatwise through the skin, and caused to traverse the cyst or cysts, making a free opening in them. Pressure with the thumbs will then readily diffuse the contents, and a pad and bandage will frequently effect a cure. In other cases, where the thick annular ligament of the wrist is lifted up by a subjacent cyst, Mr. Bellamy prefers free incision, pushing the knife straight into the sac through the annular ligament and integument, dividing these structures thoroughly; the contents are then evacuated externally, and a strong pad or compress is kept on for some time. It is remarkable how rarely even the slightest inflammation supervenes, and how thoroughly the ganglion is destroyed without

further applications. He has cured large obstinate ganglia by passing setons through them, but this was after the ordinary methods of treatment had failed.

## WESTMINSTER HOSPITAL.

Mr. HOLTHOUSE's most frequent method of proceeding in simple ganglia about the wrist is, first to flex the joint to the utmost, and make firm pressure on the tumour with the thumbs. Failing to get rid of it by this means, he passes a single thread through it; again makes pressure as before, and so empties it through the apertures made by the thread. The two ends of the thread are then tied together, and a compress applied. In the course of one, two, three, or more days, according to the amount of inflammation set up, the thread is removed; the inflammation subsides, and the ganglion is cured. Mr. Holthouse never adopts this plan of treatment unless he can see the patient within twenty-four hours, lest inflammation of an unhealthy character or too violent should be set up. Failing this condition, he punctures the tumour with a tenotomy-knife; squeezes out the contents; applies a firm compress over it; and straps it tightly round a splint placed on the palmar aspect of the wrist. There is a variety of ganglion with the pathology of which Mr. Holthouse is not well acquainted. It appears suddenly, without obvious cause, and cannot be distinguished either by its appearance or feel from an ordinary ganglion. It differs from this, however, not only in the mode of its appearance, but in its not forming a perfectly closed sac. Under pressure, it may be made to disappear completely, and without rupture of its walls: for this reason, Mr. Holthouse always first tries pressure and manipulation of the tumour before resorting to seton or puncture.

After a considerable experience of the various methods of treating ganglion, Mr. FRANCIS MASON believes that, in those cases in which the cyst has a thin wall, the forcible rupture with the thumb or a flat book is the simplest and best plan of effecting a cure; but in cases of long standing, or those in which the sac is very thick, by far the least painful and most successful proceeding is to puncture the cyst in a valvular manner with a grooved needle (a hare-lip pin does equally well); and, having traversed the contents, to make five, six, or more punctures in various parts of the cyst, especially on the opposite side, taking care not to wound the skin in this situation. On the needle being withdrawn, pressure with the thumb evacuates the contents of the sac into the surrounding tissues; absorption ultimately ensues; and, if the precaution be taken to place a pad of lint, secured with a bandage, over the part, the cyst seldom, if ever, re-fills. With regard to the common and popular method of suddenly rupturing ganglions with a book, Mr. Mason has remarked that, when the ganglion is tough, no little skill is required to strike the part so as effectually to accomplish the object in view; and another point of some importance is that, if the cyst be not broken at the first attempt, the patient is unwilling to have the blow repeated, much discomfort being occasioned by this somewhat apparently coarse procedure. Again, a book of suitable size and shape is not always at hand. Moreover, the proceeding is in many instances, even if successful, attended with considerable pain, generally causing extreme pallor, and not unfrequently inducing a fit of fainting. Few patients object to the prick of the needle, provided they have the assurance that there is no "cutting operation". Iodine paint at the onset may be tried, but permanent good seldom follows from its use. The removal of the cyst by excision is seldom absolutely necessary; and when the operation is performed, it is, as Mr. Mason has seen, sometimes followed by intense inflammation of the sheaths of the tendons, accompanied with profuse suppuration, and leaving the use of the fingers much impaired, not to mention the constitutional irritation set up, endangering the life of the patient. Such cases are of course rare; but the practice of puncturing the cyst in the way already described is, so to speak, painless, and is almost entirely free from risk in any shape.

Mr. RICHARD DAVY pursues the following methods amongst the out-patients; viz., excision, partial or complete; subcutaneous slicing; subcutaneous puncture, and injection of tincture of iodine; mechanical crushing; and subcutaneous puncture. The seton, being a tedious and painful process, has not been employed.

## GREAT NORTHERN HOSPITAL.

Mr. GAY has tried a variety of ways, with different success in different cases. His experience has led him to the conviction that these burse must be treated with caution, and that danger may accrue at least to the limb if such a rule be not observed in every case. Rupturing the cyst by violence, with subsequent pressure, is of little or no avail. The cyst has, in his experience, repaired the injury and become refilled. External puncture, and even free incision, followed by compression, have been more successful. A series of blisters, followed by

some irritant application, such as tincture of iodine, has occasionally succeeded, especially if the cyst be subsequently punctured externally, the contents squeezed out, and compression be ultimately applied. In these cases, the blistering must be continued so as to ensure the propagation of the excited inflammatory action to the inner lining of the cyst. Mr. Gay has not tried iodine and other injections. He has removed these cysts on two occasions, and with results that determined him not to attempt this mode of treating them again. In the first instance, the operation was followed by a violent attack of diffuse subcutaneous cellulitis and acute inflammation of the wrist-joint, which proved serious, although ultimately the limb and joint were saved; and in the second case the healing of the wound was very prolonged, and was attended with deep-seated suppuration and some permanent contraction of the extensor tendon. The plan which Mr. Gay usually follows (and uniformly with success) is that by seton. He passes a single thread of silk through the cyst, and allows it to remain until undoubted pus issues from the punctures. He employs a needle so large as to permit of the contents of the cyst being expressed through the openings which it makes; and, in case the thread does not excite sufficient inflammatory action, he not only moves it daily, but soaks the thread with tincture of iodine, and draws the portion thus soaked within the cyst. Even this plan is sometimes followed by severe inflammation and suppurative action, when the thread has had to be taken out. Occasionally, it has been so severe that he has had to open the cyst as an abscess. For the most part, however, the process is simple; no superfluous action is set up. About the seventh day, some pus exudes with the thread; the thread is then withdrawn; gentle pressure is applied; and the cyst contracts and disappears, all but its walls. Even when treated thus, the case must be under daily observation.

Mr. W. ADAMS thinks that, in the simplest form of ganglion, such as that frequently seen over the carpus, when recent, rupture of the sac by a sudden blow, or by hard pressure with the thumb, should first be tried, and will frequently succeed, even if it have to be repeated once or twice. This failing, he always resorts to a free subcutaneous section of the sac in different directions, by introducing a tenotomy-knife; and, after transfixing the sac, cutting freely in one direction, and then turning the knife, cutting as freely in the opposite direction. If the thin ganglionic sac appear to yield before the knife, the latter may be partially withdrawn, and the point made to pierce the sac in two or three situations. Firm pressure must afterwards be made by means of a piece of metal or small coin, wrapt round with lint, and kept in position by a bandage for a week. By this means he has generally succeeded in obliterating ganglia by one operation. Occasionally, however, failure occurs; and either the same operation may be repeated, or a seton may be introduced. In employing the seton, Mr. Adams always introduces six threads, and removes three on the following morning. This at once allows the fluid to escape, and relieves the inflammatory tension and pain produced by the seton. The remaining three threads may be allowed to remain for a week or more. From a neglect of this rule of removing half the seton, he once saw acute suppurative inflammation extend to the wrist-joint in a man under the care of the late Mr. Mackmurdo at St. Thomas's Hospital; and the patient died. The preparation, showing complete destruction of the articular cartilages of the carpal bones, is in the museum of St. Thomas's Hospital. Mr. Adams believes the seton to be a perfectly safe and reliable remedy, if half the silk be removed on the day following its introduction; but it may occasionally fail, and in two instances he has cured an obstinate ganglion by a second introduction of the seton. To what extent ganglion may be dissected out with safety, he cannot say; but in one instance, mistaking the character of the tumour, Mr. Adams dissected out a large ganglion of a flattened and lobulated shape, which had formed over the extensor tendons as they cross the ankle-joint. He mistook it for a fatty tumour, such as he has seen in the forearm. On section, the ganglion was seen to be thick-walled and lobulated; and, from its flattened and expanded form, he does not think a seton could have been employed. Metal sutures were used, and Dr. Richardson's collod. amygd. with cotton-wool applied. Guided by the first intention rule place. Old thick-walled bursal tumours over the patella, we know, have frequently been removed with safety.

Mr. EDWIN SHILLIBE always treats simple ganglion by subcutaneous puncture with a grooved needle, thoroughly emptying the cyst, and irritating its interior by a few scratches with the point of the needle. He is particular in keeping pressure upon the emptied cyst until he can apply a firm pad, which is retained in place by plaster and bandage for a week or so. It very seldom fails to cure, if thoroughly done. If it do, he repeats it immediately the cyst commences to re-fill. After the bandages are removed, he orders the application of iodine or frequent doublings of cold water. Mr. Shillibe has seen

awkward results from the use of setons; and he believes, in the treatment of simple ganglions, that they are unnecessary. Compound ganglion requires much more careful treatment, partly on account of its extent and position, partly because its contents are mixed up with more or less solid fibrinous deposits. They occur chiefly in the palm of the hand and side of the sole of the foot. He has cured those on the palm of the hand by dissecting out a portion of the cyst, without division of the annular ligament—squeezing out the remainder of the semi-solid contents, and allowing the wound slowly to granulate up. Mr. Shillibe says he should not hesitate to inject iodine in such cases.

[To be continued.]

## NOTES ON BOOKS.

*The Reports of the Medical and Surgical Registrars of the Middlesex Hospital for the year 1870* present, as usual, a considerable mass of statistical and other material arranged with much care and labour. Among other matter, Dr. JOHN MURRAY, who up to the end of the year filled the office of Medical Registrar, gives an elaborate tabular analysis of the morbid appearances observed in the various organs in one hundred and twenty *post mortem* examinations of patients who died in the medical wards; and a tabular view of the histories of 123 cases of acute and subacute rheumatism, special regard being paid to the presence or absence of cardiac disease, and to the family history. Mr. HENRY MORRIS, the Surgical Registrar, gives an analytical table of the results of *post mortem* examinations (91 in number) of surgical patients, besides very valuable tables of the cases of cancer, infectious diseases, hernia, and compound fracture. Such reports as these not only indicate work done, but, from the evident care with which they are compiled, they are valuable contributions towards the collection of a mass of facts from which, at some time, important conclusions both in medicine and in surgery may be drawn.

*The Use of the Laryngoscope in Diseases of the Throat* (3rd edition), and *Essays on Growths in the Larynx*, by Dr. MORELL MACKENZIE (London, Churchill, 1871) are two monographs of first-rate merit—better than we altogether like to acknowledge, considering that they are the result of work at an institution to which, on public and professional grounds, we think that the great objections which have been made should be steadfastly maintained. Of course excellent work may be done at an objectionable institution, just as very poor work may be done at those of the highest worth and of classical reputation. Dr. Mackenzie's essays would do honour to any place; and he has used the opportunities afforded to diligence and skill by the introduction of a new diagnostic instrument, to make solid and enduring contributions to science and practice. Both works are throughout models of honest and complete work, and are honourable to British medicine, as they are useful to practitioners of every country. The completeness of the clinical records, the excellent and abundant graphic illustrations, and the fulness of bibliographical references, are excellent features in both volumes—notably in the essay on Morbid Growths.

In noticing a further edition of SQUIRE'S *Companion to the Pharmacopœia*, we have to speak especially of the useful analytical list of mineral spas which he has added, and the extreme pains taken to make this really admirable book more and more worthy of its extended and well-earned popularity.

## REPORTS AND ANALYSES

### IN MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

#### GRANULAR EFFERVESCENT PREPARATIONS OF PEPSINE.

MESSERS. YOUNG and POSTANS, of 35, Baker Street, W., have submitted to us specimens of their new Granular Effervescent Preparations of Pepsine. In these preparations, the ammonio-citrate of bismuth, ammonio-citrate of iron, and pig's pepsine, are used. The flavour of a little essence of lemon is then added, and the granules are then made at a temperature not exceeding 90 deg. Fahr. By means of this low temperature, the otherwise delicate properties of the pepsine are entirely preserved. We believe that many members of the medical profession have already greatly approved their use, and appreciated the form as at once elegant and agreeable.

# THE GENERAL MEDICAL COUNCIL ON EDUCATION AND REGISTRATION.

SESSION, 1871.

Tuesday, July 4th.

THE Council assembled at 2 P.M., at the office, 32, Soho Square.

*New Members.*—The official notifications of the appointment of Mr. Quain as representative of the Royal College of Surgeons of England in the room of Mr. Caesar Hawkins, and of Dr. Gull as member nominated by the Crown in the room of Dr. Rumsey, having been read, these gentlemen were introduced and took their seats.

*President's Address.*—The President, Dr. PAGET, addressed the Council as follows.

On the two former occasions in which I had the honour of opening a Session of the Council, I did it in the fewest words. I spared your time, knowing its value, and could well spare it, because the business of the Session was plainly and unmistakably before us, and any introductory remarks of mine would have been at least superfluous. On the present occasion, the circumstances are different, and in one respect peculiar. What has happened since our last meeting might seem to demand comment, perhaps lengthened comment. But I will not detain you long. We meet for business, not for talk, except such talk as may be in itself business. But one word for two friends of ours who have retired from the Council since our last meeting. We should be ungrateful if we omitted to acknowledge what we owe to Mr. Caesar Hawkins—to his diligence in business, his conscientious accuracy on which we could always rely, and the clear judgment and honourable spirit which he brought to the consideration of every question; and to Dr. Rumsey it is due that we should remember his great and willing sacrifice of time and labour while aiding us in the large and complicated subject of State Medicine, of which he is so perfect a master. The services rendered by these gentlemen to the Medical Council were, in fact, rendered to the general public. The public may overlook them, or fail to acknowledge them: we cannot, and ought not. Our last meeting was wholly occupied in considering the Medical Amendment Bill of the Lord President of the Council. I regret that it was necessary to withdraw it. I believe that it would have accomplished a vast amount of good. I believe that it would have removed the chief obstacles to the further improvement of the education of the medical profession, the real obstacles to the advancement of its social status, and the more general attainment of professional excellence. It would thus have conferred great—very great—benefits on the public; I therefore regret its loss. But I have satisfaction in remembering that this Council, after long and careful consideration, expressed an approval of it, and a wish that it might speedily become law. It has been sometimes said, or insinuated, that this Council has more regard for the interests of the medical corporations and universities than it has for the interests of the public. If there be any candid man who thinks thus, I would ask his attention to the vote of the Council on the Bill of Lord De Grey. That Bill proposed in its chief and leading provision to deprive all the universities and medical corporations of their ancient privilege of granting licenses to practise medicine—a privilege which in the case of the corporations is the most important they possess. The Council, early in their discussion of the Bill, expressed a doubt of the necessity or expediency of this sacrifice of ancient privileges—a sacrifice which might not improbably be injurious to all the corporations, and might even endanger the existence of some of them. Yet, after careful consideration of the whole Bill, this Council approved of it by a majority of fifteen to three. Perfect unanimity of course could not be expected on a measure involving so great a number and variety of details. But to any person who finds fault with the constitution of the Council because he believes it to represent unduly the interests of the corporations, I would commend the vote of fifteen to three as a fact worthy of consideration. It is not necessary for me to enter upon the causes which led to the withdrawal of Lord De Grey's Bill. Neither is it necessary for me to discuss the merits of the two Medical Bills which were introduced into the House of Commons by private members in the present session. They have been withdrawn. Yet they have not been without use, if their discussion has diffused more knowledge on a subject of which the general public is profoundly ignorant, and many members even of the medical profession are still imperfectly informed. Among

the business of our present session, will be an inquiry into the conduct of a qualified medical practitioner. We shall have to inquire, under the provisions of the 29th section of the Medical Act, whether he has been guilty of "infamous conduct in a professional respect." The charge against him is that he authorised another person to affix his name to false certificates of death—false in this respect, that they stated him to have been in professional attendance on the deceased, which, it is said, was contrary to the fact. Charges of this kind have been made against two practitioners. The complaints were made originally to the Registrar-General of Deaths and the Secretary of State for the Home Department, and by them the complainants were referred to this Council. In accordance with standing orders, a preliminary inquiry has been made by the English Branch Council. In one of the cases, it was found that the evidence was scanty, and the circumstances such as, in the opinion of our solicitor and that of the Branch Council, would not fairly warrant a charge of infamous professional conduct. In the other case, it was thought proper that the charge and the evidence in support of it should be submitted to your judgment. I have mentioned this case, not merely because it is the first in which charges of this kind have been brought under your notice, but because I desire your opinion as to whether one part of the procedure, namely, our deliberation on the merits of the case, should be public or private. Of course the hearing of the case will be public, and the decision will be public; but it has appeared to me worth considering whether there should be a short intervening time in which our deliberations should be private. The deliberations of juries are private; so are those of magistrates at sessions, and those of judges when they sit in a body. In all those cases the deliberations are private, though the decisions are given publicly. Whatever difference of opinion there may be in the Council on this suggestion of mine, I am satisfied we shall be agreed on taking the course which appears to us the most likely to lead to a just conclusion—just towards the person whose conduct is impugned, and just towards the profession and the public, who would have good reason to blame us if we shrank from exercising aright the powers conferred on us by the Medical Act.

*Committees.*—The following committees were appointed:—*Business Committee:* Dr. Andrew Wood, Chairman; Dr. Embleton; Dr. A. Smith; and Dr. Leet.—*Finance Committee:* Dr. Sharpey, Chairman; Dr. Risdon Bennett; Dr. Quain; Dr. A. Smith; and Dr. Fleming.—*Committee on the Registration of Medical Students and on the Returns from Examining Bodies:* Dr. Embleton, Chairman; Dr. Fleming; and Dr. A. Smith.

*Returns from Public Departments.*—Statements of the Degrees, Diplomas, and Licences, of the candidates who presented themselves in February last for commissions in the Medical Department of the Army and in that of the Indian Army, were presented. From these it appeared that, for medical commissions in the army, 57 candidates presented themselves, of whom 36 were successful, while of the remaining 21, 17 were found qualified, but were not accepted, only ten appointments being made. For commissions in the medical service of the Indian army there were 23 candidates, of whom 10 were admitted, and 9 out of the remaining 13 were, though qualified, unsuccessful on account of there not being a sufficient number of vacancies.

Sir DOMINIC CORRIGAN moved, Dr. ANDREW WOOD seconded, and it was resolved:

"That the returns from the medical departments of the army and of the Indian army be entered on the minutes."

*Medical Acts Amendment Bill of 1870.*—Dr. ACLAND, in pursuance of a notice which he had given, asked the President whether he would inform the Council for what reasons the Medical Bill, brought forward after the last meeting of this Council in the last session of Parliament by the Lord President of the Privy Council, was, after much consultation with a committee of the Medical Council, not proceeded with in the House of Commons after it had passed the House of Lords. He said: In putting this question it is unnecessary that I should dilate upon it further than just to remind the Council of the circumstance, that when we broke up at our last meeting, we parted with the expectation of meeting again with fresh powers and fresh duties, and a committee of the Council was appointed to confer with the Lord-President. As the Council is aware, the Committee did so to the best of their ability; and the result was the passing of a Bill through the House of Lords, which Bill was afterwards dropped. It seems to me, therefore, to be expedient for our own sakes, and for the sake of the public, that a formal question should be put to the President in order that he may officially tell us if he has any knowledge how it was that the legislation which was expected to give us new powers and new duties fell through. Before I put the question formally, I would only add that we are now, as I understand it, *in statu quo*—that is to say, after a great deal of deliberation, which in one form

or another has gone over two or three sessions, we have to begin again and carry on our work with the same powers as we had before, and that in entire uncertainty whether we shall have any new powers or duties assigned to us. I see that there is a notice of a question referring to this last-named subject, and therefore I will only put the question of which I have given notice.

The PRESIDENT—I have no special information on this subject—at least no official information. Most of you know that an answer to this question was included in some remarks by the Vice-President of the Council, Mr. Forster, in the debate on the 14th June. I sent for a copy of *Hansard* in order that I might read his very words, but, curiously enough, *Hansard* for that night cannot be obtained. I will read you Mr. Forster's words from a newspaper report, the accuracy of which I have no reason to doubt. "Mr. Forster said that legislation had failed last year because, although the Bill which had been introduced in the House of Lords had been most carefully considered, it had been thought desirable when the Bill came down to that House (the House of Commons) to add to the question they were then attempting to settle the other question of the constitution of the Medical Council, and it was then too late in the session to deal with the subject." Of course I have the same information as most other persons have as to some of the causes of the withdrawal of the Bill, but I do not know that I should enlighten you by mentioning them. I wish to give, however, as complete an answer as I can to the inquiry. It was known that the Bill was opposed, that some medical corporations petitioned against it, and that it was energetically opposed by a committee of the British Medical Association. It was also well known that the session was drawing to its close. I believe that not more than a fortnight remained, and the little time that did remain was shortened unexpectedly by one or two debates incidental to the breaking out of the war between France and Germany; and it was quite clear that any serious opposition, or at all events any obstruction, to the Bill would be fatal to it. Some members of the House, in concert with, or representing, the Committee of the British Medical Association, expressed their intention of opposing the Bill; and they insisted on its being enacted that a certain proportion of the members of the Council should be elected by the direct votes of all registered medical practitioners. They said they would obstruct the Bill if that were not granted immediately, or a promise given by the Government that should be binding for the following year. The Government objected to that, because, as it was a question in which there was a difference of opinion, a discussion was absolutely necessary, and there was no time for discussion. Under these circumstances, Mr. Forster offered on the part of the Government that, if the Bill passed unobstructed, and if any private members were to introduce another Bill in the following session for the purpose of securing the direct representation of the profession in the Council, the Government would assent to the Bill being referred to a fair select committee without prejudging the question themselves. This offer of the Government was refused by some members of the House, acting with the Committee of the British Medical Association. As there was no time for discussing the matter, Mr. Forster was, as I understand, under the necessity of withdrawing the Bill. That is all that I know upon the matter, and I have stated it as accurately as I can.

Dr. STOKES—I beg to ask the President if he is aware whether the Government proposes to bring forward the same or any other medical Bill either in this or any subsequent session; and, if so, whether he will inform the Council.

The PRESIDENT—The answer which I have to give is much the same to which I gave to the first question. It is a question which, under ordinary circumstances, I should have thought it proper to refer directly to the Government in order to ascertain what their intentions were, but I did not think it necessary or advisable to do so under the circumstances; for in the same debate of the 14th June Mr. Forster made this statement: "From the number of questions pressing on the Government for legislation, he could not pledge them to bring in a Bill next year, but it was their wish and anxiety to do so. If they were unable to deal with the subject next year, and if any private member would take up the subject, no obstacle would be thrown in the way of the fullest consideration of it by the House; and, if it were desirable, the Bill might be referred to a committee upstairs." That is the only information I have; and the statement being so recent as the 14th June, I thought it scarcely advisable to make any further inquiry.

*Preliminary Examination.*—The list of examining bodies, whose examinations fulfil the conditions of the Medical Council as regards preliminary education, which had been prepared by the Executive Committee, was laid before the Council. It was the same as the list of last year, with the following addition: "The examiners for examinations in the military and naval services of the United Kingdom; certificate to include all the subjects required by the General Medical Council." On

the motion of Mr. HARGRAVE, seconded by Dr. PARKES, it was resolved that the list, with the proposed addition, be approved of.

*Professional Education.*—A report from the Committee of the Council on Professional Education was presented; and, on the motion of Dr. PARKES, seconded by Dr. STORRAR, was ordered to be received and entered on the minutes. The report, after treating of various matters of educational detail, concluded with the following recommendations.

"We beg to recommend that the Council shall address a letter to each licensing body, transmitting a copy of the resolution of the 26th February, 1870, and urging that arrangements for the formation of conjoint boards shall be undertaken without delay, so that the Council may be in a position to communicate them before the close of the year to the Government.

"And we advise, in addition, that the Council shall authorise the Executive Committee to seek an interview with the Lord-President of the Council, and to urge upon him the desirability of such medical legislation in the session of 1872 as may carry out the object the Council proposed in passing the resolution of February 1870, and which Lord de Grey had in view when he introduced his Medical Bill of 1870."

*Removal of Name from Register.*—A letter from the Secretary of the Royal College of Surgeons of England was read, stating that Mr. Edwin Lowe of George Street, Hanover Square, had been removed from being a member of the College in consequence of having been convicted of felony and sentenced to penal servitude. The diploma of member of the Royal College of Surgeons being the only qualification under which Mr. Lowe was registered, his name was ordered to be erased from the Register.

*Alleged Conviction for Misdemeanour.*—A certificate of the conviction of Frederick Henry Morris of a misdemeanour was read; and it was resolved:

"That the Solicitor of the Council be requested to obtain due information and report as to the identity of Frederick Henry Morris, convicted at Devizes, March 29th, 1871, of a misdemeanour, with the Frederick Henry Morris of Swindon, Wilts, whose name stands on the *Medical Register* for 1871."

*Petition for Restoration to the Register.*—A petition addressed to the General Medical Council by Dr. John Pattison, praying that his name may be reinstated on the *Medical Register*, was read; with a letter from C. H. Frewen, Esq. (See BRITISH MEDICAL JOURNAL, July 10th, 1869, p. 43). It was resolved:

"That, having heard the petition of Dr. Pattison to be replaced on the *Register*, and having fully considered the said petition, the Council see no reason to reverse the decision to which they formerly came, after full and careful consideration of the whole case."

*Communications.*—A letter from Dr. Edwards Crisp, with a copy of resolutions passed at a meeting of medical practitioners held on 7th May, 1870, was read; and the Registrar was directed to intimate to Dr. Crisp that his communications were received and read to the Council.—A letter from the Board of Public Examiners, Cape of Good Hope, praying the Medical Council to recognise their third-class certificate in literature and science, was read, and was referred to a committee consisting of Dr. Gull and Dr. Storrar.—A letter from the Honorary Secretaries of the Sydney Infirmary and Dispensary, requesting advice on the subject of founding a medical school at Sydney, was read; and it was resolved—"That a letter be addressed to the Honorary Secretaries of the Sydney Infirmary and Dispensary, in reply to their request for advice on the subject of founding a medical school in Sydney, informing them that it is not within the province of the Medical Council to give advice on the subject, but that the Council will forward to them copies of their reports on medical education."

*The Returns from the Army and India Medical Boards.*—Dr. ALEXANDER WOOD called attention to the erroneous impressions liable to be produced from the manner in which the statements as to unsuccessful candidates were made in the returns furnished by the Army and India Medical Boards. He moved:

"That the returns from the Army and India Medical Boards be referred to a Committee to consider and report thereon. The Committee to consist of Sir D. Corrigan, Chairman; Dr. Alexander Wood; Dr. Allen Thomson; Dr. Apjohn; Mr. Quain; Dr. Bennett." The motion was seconded by Dr. APJOHN, and agreed to.

Wednesday, July 5th.

*Charge against a Registered Practitioner.*—After the reading of the minutes of the previous day's meeting, the Council proceeded to investigate a charge of "infamous conduct in a professional respect" made against Mr. W. H. Kempster, a registered practitioner residing at Battersea. Mr. Kempster, who had received notice to attend the

meeting of Council, was present; and was accompanied by Dr. Baxter Langley, Dr. James J. Joseph, Mr. W. G. Sutcliffe, and Mr. W. Goodson.

Mr. OUVRY, the Solicitor to the Council, read a copy of the notice which had been sent to Mr. Kempster, in which he was stated to be charged with "permitting one William Goodson, an unqualified person, to practise under colour of his name, he sharing the profits of such practice, and to issue certificates of death, signed, or purporting to be signed, by him" (Mr. Kempster), "by which certificates it was made to appear that the deceased persons therein named were attended by him in their last illness, whereas, in truth and in fact, they were attended by the said William Goodson." Affidavits relating to three cases in support of the charge were also read; together with an agreement between Mr. Kempster and Mr. W. Goodson.

In reply, Mr. KEMPSTER admitted the facts stated, but said that by the terms of the agreement Mr. Goodson was engaged as his ordinary assistant. He then called Mr. Goodson as a witness, who stated that he had been engaged as assistant to Mr. Kempster for nine years. One term of five years had expired, and the other was not yet complete. He had never practised on his own account; he paid over all monies to Mr. Kempster, reserving only petty cash and his weekly salary. He consulted his principal in all cases. In a few instances, the patients had died without being seen by Mr. Kempster. Mr. Kempster signed the certificates of the cause of death, and he (Mr. Goodson) filled them up. He did not sign them himself; and in one of the instances referred to, he delayed giving the certificate until he had Mr. Kempster's signature.

Mr. KEMPSTER urged that it was evident that he did not share the profits of the practice with Mr. Goodson, who received only his pay as an assistant. With regard to the employment of unqualified assistants, he would refer to the regulations of some of the examining boards, especially the Royal College of Surgeons of Edinburgh, which recognised, as part of the education of a student, the performance of duties as visiting assistant for six months to a registered medical practitioner. Out of a large number of certificates of death which he had given during the last four years, it had been found possible to bring forward only three instances in support of the charge; and, as to one of them, he denied that he had never seen the patient before death.

Dr. JOSEPH being called as a witness, said that he knew that Mr. Goodson was only Mr. Kempster's assistant. He himself, before he was qualified, had been an assistant. It was a common practice in the profession to employ unqualified assistants. In cases of death, where the patient had not been seen by his principal, the latter sometimes signed the certificate.

Mr. W. G. SUTCLIFFE gave similar evidence with regard to the professional relation between Mr. Kempster and Mr. Goodson. He believed that it was usual for the principal to be consulted before filling up the certificate in cases where the patient had been seen by the assistant only; but in some instances, blank forms were signed by the principal, and left to be filled up by the assistant.

Dr. BAXTER LANGLEY said that unqualified assistants were formerly much in demand; but within the last two years there had been an increasing tendency to prefer qualified assistants. In branch practices, the assistant sometimes resided at a distance; and cases must sometimes occur in which death occurred without the patient having been seen by the principal. He considered that the maxim *Qui facit per alium facit per se* was applicable in the case of medical assistants. It was, from the necessity of the case, a widely spread custom for the principal to allow his assistant to fill up certificates, subject to communication with him. He considered that an assistant, in using the name of a principal with his authority, was in a position analogous to that of the managing clerk of a firm of solicitors. In answer to a question why an assistant could not sign the certificate stating that he did so for his principal, he (Dr. Langley) said that the registrar would not receive a certificate so signed. He believed that in exceptional cases unqualified assistants residing at a distance filled up the certificates without consultation with their principals, whose names were attached to them.

Mr. KEMPSTER said that he had been summoned on the same charge as was now made to Wandsworth Police Court, but the magistrate, Mr. Ingham, had decided that there was no legal offence. A complaint had also been made to the Home Secretary and the Registrar General, who had declined to entertain it. If the Council should consider that he had done wrong, he would express his sorrow, and promise not to repeat the offence.

Mr. OUVRY explained that the particulars of the charge had been supplied by Dr. Leslie, a practitioner at Battersea. Dr. Leslie had corresponded on the subject with the Home Secretary and the Registrar General, who declined to interfere, but recommended him to bring the matter before the Medical Council.

The Council then deliberated in private for some time; after which Mr. Kempster was again called in, and informed by the President that the Council unanimously acquitted him of the charge made against him.

*The Registration of Death.*—SIR DOMINIC CORRIGAN proposed—  
"That the facts which have come to the knowledge of the General Medical Council in the investigation of the case of Mr. W. H. Kempster have impressed this Council with the conviction that an amendment of the laws in force in regard to death-registry is most urgently required; and that a copy of this resolution be forwarded to the Secretary of State for the Home Department."

Dr. CHRISTISON seconded the motion. It appeared absolutely necessary that a change should be made, in order to enable medical practitioners to obey the law. There ought to be some form of certificate which unlicensed assistants could sign.

Dr. ACLAND supported the motion. The statements that had been made before the Council as to the manner in which certificates of the cause of death were filled up would no doubt cause astonishment. A more tortuous state of the law, and one more unfair than that which now existed, could not be conceived. Further, the evil was connected with many others bearing on the profession and the public; and all this tended to indicate the necessity for the formation of a Public Health Department in the Government. Mr. Stansfeld had given notice of his intention to bring in a Bill for the formation of such a department; and it was the duty of the Council to support such a measure, which would affect the health and welfare of all.

Dr. ALEXANDER WOOD agreed as to the necessity for amending the law relating to registration of death. In Scotland, it sometimes occurred that the certificates were signed by unqualified persons, who had not seen the patients before death.

Dr. STOKES said that the certificate of death contained matters with which a medical man had nothing to do—such as the age and the duration of illness. Again, it was not always certain that the person was actually dead. Sir D. Corrigan had once been asked to sign a certificate, and had refused; on going to the house a few days afterwards, he found the man still alive. The cause of death, also, was a most difficult question. The medical man ought to be called on to certify only to the best of his belief.

The motion was put to the vote, and carried unanimously.

Some formal business was then transacted, and the Council adjourned.

On Thursday, the Council was occupied during the entire sitting in the discussion of subjects treated of in the Report of the Committee on Professional Education. Resolutions were passed in favour of separating the instruction in Pharmacy from that in Therapeutics, and of giving the former at an early, and the latter at a later period of the professional curriculum; of introducing systematic instruction in Pathological Anatomy into the curriculum; and of making class-examinations a necessary part of professional education. A motion for increasing the duration of instruction in midwifery was, after considerable debate, negatived.

#### SINGULAR MUNIFICENCE.

In alluding to new charities, the *New York Medical Journal* mentions a splendid institution, the Stranger's Hospital, erected and equipped by the munificence of a single individual, Mr. Keyser, of that city. This hospital is located at the corner of Avenue D and Tenth Street, a portion of the city far away from the public hospitals, and yet crowded with a population compelled by their poverty largely to rely upon such institutions in case of sickness. The building will accommodate about two hundred patients, and, in its appointments, is certainly one of the completest hospitals in this city. Everything has been subordinated to the convenience and comfort of the patients, and it is doubtful if there can be found in the country any more perfect provision for ventilation, heating, and water-supply and waste, than is to be seen here. All this work has been done under the personal almost constant supervision of the donor, who, besides the expenditure necessitated in the construction and outfit, amounting to upwards of one hundred and seventy-five thousand dollars, also provides the means for the current expenses of the institution. Such noble charity as this carries its own reward, and yet none the less on that account ought it to receive the commendation and gratitude of all classes and professions. The attending medical staff consists of Drs. F. N. Otis, T. G. Thomas, H. B. Sands, and William H. Draper, assisted by Drs. R. W. Taylor, James L. Brown, T. T. Sabine, and E. C. Seguin.

THE Subscriptions to the Association for the year 1871 became due in advance on January 1st. All which are not already paid, should be forwarded to the General Secretary, Mr. T. Watkin Williams, 13, New Hall Street, Birmingham; or to the Secretaries of Branches.

## BRITISH MEDICAL JOURNAL.

SATURDAY, JULY 8TH, 1871.

### COLLECTION OF SUBSCRIPTIONS.

AT a special meeting of a Committee of Secretaries of Branches held at Birmingham on June 6th, it was unanimously agreed to recommend that all Branch Secretaries should be officially requested to issue circulars for the collection of subscriptions in the months of January, April, July, and October. This, it was found, accords generally with the practice of those Secretaries who have been found to be most successful in collecting the subscriptions from the members of their Branches. This recommendation was approved and passed by the Committee of Council (JOURNAL, June 17th, p. 650). The forms which will ultimately be adopted are still under consideration, and are being framed by the Subcommittee of Local Secretaries then nominated. Meantime the ingenuity of each Local Secretary will of course be in a position to issue a form satisfactory to himself. In calling attention to the above resolutions, therefore, we desire to suggest that Local Secretaries should act upon them at once, at their discretion. We may mention that in some Branches, where the current subscriptions in arrear are thus looked up, the ultimate loss from arrears amounts to less than two per cent. (and this in a large total number of members); while in others, where it is omitted or less carefully adopted, they run up to fifteen or twenty per cent., and even a higher percentage, thus involving a great loss to the Association at large, as well as to the Branches concerned.

New members are now admitted for the current half-year at a subscription of half a guinea. The number of July 1st commenced a new volume. The present is, therefore, a favourable time for enrolling new members, to add to the permanent strength of the Association.

### THE CONJOINT EXAMINING SCHEME.

We are happy to learn that the Joint Committee of the London Colleges have now agreed upon a plan of conjoint examination, based upon the scheme presented by the College of Physicians, of which we have already explained the main features. The English Universities have also, we believe, accepted the proposals of this scheme with favour. We regard this step as one of great value and importance. It will, when the details are settled, provide an uniform minimum examination for England of a complete and satisfactory character. Thus one great step towards Medical Reform, steadily and consistently urged by this Association for years, will have been voluntarily consummated by the English Universities and Corporations. It does them honour, and will confer a lasting benefit on the profession and the public. We shall venture to express the hope that a similarly harmonious measure of reform will commend itself to the medical institutions of the sister kingdom. Some ardent spirits have declared that reform, to be satisfactory to the profession, must include the destruction and degradation of the medical faculties of the Universities and examining boards of Corporations, as proposed by the Bill which was brought forward without support this year in the House of Commons. We are persuaded that the real wish of the profession is to see those bodies elevated, purified, and enlarged, fulfilling their functions in a liberal and catholic spirit, and continuing

to advance the cause of medical education by free, elastic, and individual co-operation in the work of education for which each of them has its own special fitness. This accords with the genius of English institutions, and with the honour and capacity of liberal professions. It is in this spirit that the British Medical Association has sought to promote medical reform, and for these reasons we hail with pleasure the mutual arrangement which we have the satisfaction of being able to-day to announce.

### THE GENERAL MEDICAL COUNCIL.

THE session of the Medical Council for 1871 is not likely to be very eventful or very protracted. The President detailed the causes which led to the withdrawal of the Government Bill of last session. That history is now well known to the members of our Association. The opinions of the profession had been expressed, within and without the Association, in favour of direct representation as a *sine qua non* of medical reform, by the voice of numbers beyond precedent, and with a force, unanimity, and earnestness which might well have convinced the Council and the Government that it would not be put aside. When the time came for parliamentary decision, it was found that the Government measure included no provision on the subject; and the Medical Council, which had received a perfectly clear, explicit, and definite expression of those views from a formal deputation of the British Medical Association, took no step, in its communications with the Government concerning modifications of the Bill, to raise that question. It ignored what the profession and the Association declared to be vital. Many will think that this fact in itself indicated how far the Medical Council is from being fully representative of professional opinion, and how necessary, therefore, was the reform demanded. The Government and the Council having alike ignored the written declaration of ten thousand practitioners, it became the duty of the executive of our Association to take action for the profession, whose views were being treated with something very like silent contempt. They stood manfully to their duty. At great personal inconvenience, cost, and labour, the leading members of the Direct Representation Committee of the Association came to town and went to work independently when they found the views which they were appointed to represent thus put aside. They were offered at the last moment a compromise; they were told that the Government would not oppose a separate consideration of the question of the constitution of the Council, if they allowed this Bill to pass unobstructed. The responsibility was grave, and was felt to be such. But they had an old experience which told them that, in such a case, piecemeal legislation is fraught with dangers. They remembered that similar promises, held out long ago on a similar occasion, had not sufficed to produce a practical result. They were advised that, the main public questions once settled, there would be extreme difficulty in reopening subsequently a part of the case which was more purely professional; and that, by letting the Bill pass as it was, they would lose a great part of their power to obtain what the profession required: they would have to meet the opposition of interested bodies, without any help from those now interested in passing their general measure, and willing to give and take. In fine, to have consented to the course proposed would have been, as they were advised, and in their opinion, to sacrifice the principle which the profession had extensively endorsed, and of which they alone stood forward as the solitary champions. They did their duty as they understood it; they did it well; their course has been endorsed by the Association; and, except in the Council itself, not one medical society or body or collection of individuals has ever had one word of blame for their proceedings. We understand, and we largely sympathise with, the regrets which Dr. Paget expressed, and of which he stated the grounds with force and precision. If we decline to adopt his conclusions, it is not because we deny the premises from which he argues, but because we hold his argument to be incomplete. It reckons with the public, the Corporations, and the Government; but it does not adequately gauge the strength,

endurance, and vitality of the professional feeling in and out of the Association, but working through its organisation, which demands as a *sine quâ non* that which Dr. Paget and some other distinguished men were content to ignore when they had the opportunity of representing it to the Government, and which they still hold to be either ill founded or of secondary importance.

The encouragement which Mr. Forster gave to private members to bring forward their schemes next year will, we suppose, put the Council on their mettle this year. The first necessity for their better success is, that on this point they should place themselves more nearly in harmony with the general opinion of the profession.

#### THE ELECTIONS AT THE ROYAL COLLEGE OF SURGEONS.

THE elections of the Council of the Royal College of Surgeons of England took place on Thursday, and we announce the result in another column. Mr. Le Gros Clark, Mr. Spencer Wells, and Mr. George Crichtett, were elected by almost equal numbers. The number of plumpers polled for Mr. Cock attests the personal attachment of his old pupils and friends, and the desire of many Guy's men to do honour to their valued teacher. The Conservative party were of course true to their attachments, and paid him a parting tribute of wasted votes. Mr. Busk, by the sheer force of personal character, acknowledged eminence, and the respect due to his ability, earnestness, and independence, triumphed, unaided by party following or the close attachment of a large family of pupils and adherents, and received the merited honour of re-election to a position which he fills with eminent usefulness, and from which he will rightfully step in due course into the Presidential Chair, although possibly with an interval of a year, for we hope Sir William Ferguson's term of office will be prolonged thus far. Mr. Barnard Holt occupied a position sufficiently high to insure his due election in turn. On this occasion, as for a now unbroken succession of years, the precise list of candidates which we have been led to select as that having the greatest claim on the majority of votes has been returned; and the test of the ballot-box has confirmed our independent judgment. It is now some years since any provincial candidate for the Council has presented himself. There is more than one who might fairly now make this sacrifice to his professional duties; and we hope next year to find the provinces in the field.

#### THE VITAL STATISTICS OF THE BRITISH ISLES.

WE have compiled, from various analyses of the census of 1871, just published, information which will be acceptable to our readers.

The enumerators collected 5,030,895 schedules from families or lodgers living in 4,259,032 houses. The enumerated population of England and Wales on April 2nd was 22,704,108 souls—an increase of 2,637,884 over that at the preceding census. This is in excess of the estimated growth. The increase from 1851 to 1861 was 2,138,615, being at the rate of 12 per cent. for the ten years; whereas that for 1861-71 is 13 per cent. The actual increment was larger than in any preceding decenniad, although the ratio of increase was higher in the period 1811-21, amounting to 18 per cent. The ratio had declined until the present decennium. In 1801, when the first census was taken, the population at home amounted to no more than 8,892,536, a number almost equalled by the mere increment of population since 1831. The causes of the more rapid growth of population in the last decennium awaits explanation from further analysis.

The relative movement of population in the urban and rural districts is disclosed by these returns. That of the urban districts has in the last ten years grown more than twice as fast as that of the country districts. The former include 12,900,297 of the population, and the latter 9,803,811. The decennial increase in the former is 1,969,456, and in the latter 668,428. The former population has grown at the annual rate of 1.67 per cent., and the latter at the annual rate of 0.71 per cent. But the growth of the urban districts has not been so great

as in the previous decenniad, while that of the rural has been more so. In 1851-61, the urban population increased 1.79 per cent. per annum, against 1.67 in 1861-71; whereas the rural population increased at the rate of 0.41 per cent. in the former period, against 0.71 in the latter. The progress of the ratios is thus reversed. This is said to imply that many rural districts are assuming the character of towns—villages becoming towns, small towns growing large; the town is spreading into the country. The number of inhabited houses has increased by more than half a million. The average number of persons to a house is 5.3. The number of uninhabited houses (in which no person dwelt or slept on the Sunday night preceding the enumeration) is 260,178, as against 184,694 in the year 1861. In towns, many of these houses were occupied during the day. With regard to the proportion of sexes of the population, the females number 11,663,705, and the males 11,040,403—an excess of 623,302 women and girls. Estimating soldiers and sailors abroad at 149,254, the excess of women is reduced to 474,048.

Summing up the totals for the British Isles, the following figures result. Including 207,198 abroad in the army, navy, and merchant service, the population of the British Isles is enumerated as 31,817,108. Of these, England has 21,487,688; Wales, 1,216,420; Scotland, 3,358,613; Ireland, 5,402,759; the Isle of Man, 53,867; and the Channel Isles, 90,563. Out of every 100 of the population, England owns 67½, Wales not quite 4, Scotland upwards of 10½, and Ireland 17. The daily growth of the population of the whole kingdom is at the rate of 725 persons. The decennial rate of increase was 6.06 per cent. in 1851-61, and the annual rate 0.59 per cent. In 1861-71, the decennial rate was 8.96 per cent., and the annual 0.86 per cent. The increasing rapidity of the growth is thus evident. Distinguishing the sexes, the male population of the United Kingdom appears as 15,549,271, including soldiers and sailors abroad; and the female as 16,267,837. It is believed that the 718,566 absent males are to be found elsewhere; and the Registrar-General refers to the ascertained fact that, about the year 1861, there was an excess of more than a million males in the colonies and the United States, the latter alone showing a male surplus of 735,429 in 1860. Emigration from the United Kingdom has been going on steadily, but at a retarded rate. The emigrants in 1851-61 were 2,054,578. In 1861-71, they were 1,674,794, the decrease being 379,984. The decrease in emigration helps to account for the increased growth of the population—bearing in mind that not only were so many more individuals retained, but a portion of them have become the parents of children born within the decenniad.

One of the most interesting considerations arising out of the study of the census relates to the forecast of future growth of the population. An able writer in the *Standard*, in analysing these returns, points out that at the present rate England will double her population in fifty-six years, and the United Kingdom in eighty-four years. It is expected that the population will increase pretty uniformly for some years to come. Euler showed on mathematical principles how rapidly men can multiply, proving that it was quite possible for the millions of the human race to have sprung from one pair within a moderate period. Malthus, by an elaborate statistical deduction, established the principle that population grows naturally at rates in geometrical progression. In this report we find it argued—and the argument is doubtless sound—that a prolific population is by no means a source of peril as affecting the means of subsistence, but rather the contrary. But for its prolific power the English race would now have no existence. The dangers and disasters of its infancy in the days of the Celts and Angles would have extinguished it. In 1801 the population of the United Kingdom amounted to about 16,302,410. The preceding year had been one of great scarcity, giving the people some idea of famine. The mortality was high, and the population seemed to be in danger of exceeding the limits of subsistence. But now, in 1871, with a population of nearly 32,000,000, and rapidly increasing, the pressure on subsistence is far less than it was at the beginning of the century, and products are in-

creasing far more rapidly than people. The increase in the working power of the country, brought about by the machines, tools, and engines which men of science, mechanics, and engineers have placed at our disposal, tends directly to the maintenance of a large population. The necessities of life are substantially what they were. But the opportunities are immensely increased. Men are still but men in regard to that which they consume. They are becoming giants in the power of production.

THE Infirmary for Children, Clifton Hill, Brighton, is to be formally opened on the 14th instant.

TYPHUS is diminishing in Vienna. In the week ending July 1st, fifty-nine cases were admitted into the hospitals.

FOR the future, the operations at Charing Cross Hospital will take place on Saturdays at 2 o'clock.

THE order of the Iron Crown of the second class has been conferred on Dr. Frerichs of Berlin, whose classical work on the *Liver* has made his name well and favourably known to English readers.

DURING the week from June 17th to 23rd, there were fifteen deaths from small-pox in Paris. The total mortality was 1106; in the corresponding week of 1870, it was 1149, the number of deaths from small-pox being 238.

M. RICORD has been presented to the grade of Grand Officer, and M. Demarquay to that of Commander, of the Legion of Honour, in consideration of their services during the siege of Paris. Several promotions to the grades of Officer and Chevallier of the same order have been made on the same grounds.

ONE of the medical officers of the Dudley Union, having received a circular with reference to the non-production of the medical officers' books, forwarded his to the last meeting of the Board of Guardians, with a long entry in the column for observations, from which the following is an extract. "The last time I had the honour of attending at the Board, I took my book, carefully filled up. Not a soul would take the trouble to look at it. I proposed to an intelligent guardian, well developed in the frontal region, that I should put a good-looking dummy in your possession, and he thought I couldn't do better." A little further on, he stated that "Mr. Brooks has been suffering from one shilling and sixpence a week and old age combined." The facetiousness of the medical officer roused the ire of one of the Board, who stigmatised it as "nonsense".

#### UNIVERSITY COLLEGE: THE SHARPEY SCHOLARSHIP.

THE scheme proposed for the institution of the Sharpey Scholarship has been adopted by the Council of the College. Its principal features are that the scholarship may be held for three or a greater number of years, and that the holder of it shall act as an assistant to the Professor of Practical Physiology, having opportunities afforded to him of pursuing original investigations, and having the right to use the laboratory and its apparatus for that purpose.

#### NEPHROTOMY.

DR. MEADOWS performed the operation of nephrotomy on Saturday under rather peculiar circumstances. The operation was performed for the relief of a patient who presented the symptoms usually recognised as those of ovarian dropsy, but, on opening the abdomen, the tumour was found to be a large cyst of the kidney. The true structure of the organ had almost entirely disappeared, while the other kidney was apparently healthy. Dr. Meadows, in the belief that the removal of the diseased organ presented the best method of treatment, accordingly applied a clamp, as in the operation for the removal of ovarian tumour. Although the woman exhibited symptoms of suppression of urine for twenty-four hours, she is now, we believe, doing well.

#### CHARING CROSS HOSPITAL.

WE very much regret to learn that Dr. Hyde Salter has been compelled, in consequence of the state of his health, to resign his appointment as Physician to the Charing Cross Hospital. The vacancy thus caused will be filled by the promotion of Dr. Silver. An appointment as assistant-physician will consequently ensue.

#### OUR AMERICAN COUSINS.

ON Wednesday, after doing lithotomy on an adult, Sir Henry Thompson introduced Dr. Sayre of New York, well known for his practical improvements in the treatment of joint-disease, to the students and spectators in the operating-theatre of University College Hospital. On Sir H. Thompson's invitation, he gave an instructive description of his method of treatment, by which he is able to let even the most severe cases of hip or knee disease take regular exercise in the open air or the gymnasium, while the principles of *surgical rest* are also complied with. After some remarks on the various difficulties that have to be surmounted in the treatment of acute and chronic arthritis, illustrated by anecdotes full of pungent and characteristic humour, Dr. Sayre applied his hip-splint to a patient of Mr. Berkeley Hill's. This was a lad of ten years, whose hip had gradually consolidated during many months of rest in bed. The sinuses were first thoroughly explored by the flexile probe (made rigid at will) which Dr. Sayre has contrived in order to detect necrosed bone, however devious the way to it. Then, the splint being adjusted to draw the head of the femur from the acetabulum, and at the same time to support the hip-joint, the patient was let on the ground and made to walk, which, when his timidity was overcome, he was able to do without pain. On Friday (to-day), at one o'clock, Dr. Sayre's method of extending ankylosed joints will be tried upon the retracted knee of a patient of Mr. Berkeley Hill's in University College Hospital, for whom excision will probably be necessary.

#### ST. BARTHOLOMEW'S HOSPITAL.

ON Tuesday last, the Prince of Wales, accompanied by the Princess of Wales, the Princess Louise, and the Marquis of Lorne, paid a visit to this hospital, of which his Royal Highness is President. The Governors mustered in considerable numbers to welcome the Royal party, and many ladies were present on the occasion, as was also the whole of the working staff of the institution. The Royal visitors arrived about four o'clock, and were received at the entrance by a deputation of the Governors, headed by Mr. Foster White, the Treasurer, and thence escorted to the court room, a stately apartment, where the company had assembled, and where, after some preliminary business had been transacted, the Secretary, Mr. Cross, read a resolution bearing the signature of the Prince of Wales, as President, and passed at a General Court of Governors on the 11th of May last, expressive of the sincere regret with which they had received the resignation by Mr. James Paget, F.R.S., of his office of senior surgeon to the hospital. The Court, further desiring to evince its appreciation of Mr. Paget's services, had unanimously appointed him honorary consulting surgeon. The resolution, of which that is the substance, and which was loudly cheered at the conclusion, was written upon vellum and magnificently framed. His Royal Highness, the President, said it afforded him sincere gratification to present that memorial to Mr. Paget, mingled at the same time though it was with a sad feeling, arising from the consideration that that gentleman was about to sever his connection with the hospital to which his great experience and valued services had been continuously devoted for nearly quarter of a century. He was glad, however, to think that, though Mr. Paget was about to leave the hospital as senior surgeon, his name would continue to be associated with it as consulting-surgeon, and also, he believed, as occasional Clinical Lecturer. The testimonial was hardly equal to his services. However that might be, he sincerely trusted Mr. Paget's health, which lately had not been good, would be speedily restored to him, and that he would long live to enjoy the society and esteem of his friends and

admirers. He had only further to say that, in addition to the testimonial by the Governors, a supplementary one would be presented to Mr. Paget by his pupils and the surgeons connected with the hospital. Mr. Paget, in reply, said it was with mingled feelings of pleasure and of pain that he received the testimonial—of pain because it was the signal of the close of his career as an active officer of the hospital; of pleasure because it recorded the opinion of those whose right it was to judge him that he had done his duty, still more because the judgment was recorded in terms and with proofs of confidence that were very grateful to him, and was affirmed by a signature which would insure its preservation long after all personal recollection of him and of his work would be lost. Mr. Paget said that he had to thank, first, the Governors, and especially the Treasurer of the hospital, for the long and happy tenure of office he had enjoyed, for their abundant provision of everything that could make his office useful and agreeable, for this last crowning act of their goodwill and confidence, and for their electing him consulting-surgeon. Mr. Paget offered thanks to his late colleagues, naming the chief among them, and stating that there was no professional or social virtue, no form of mental power, no variety of knowledge or of skill, which he might not have studied among them. Mr. Paget next thanked his pupils, pointing out that the majority of those now on the staff of the hospital had at some former time been among the number of his class. He concluded by tendering his thanks to the Prince and Princess of Wales, assuring his Royal Highness that his condescension would never be forgotten, and that his signature to the document gave it a value which would increase every year, for that those who would follow him in generations far off would point to it in proof that he had enjoyed the good opinion of a Prince than whom history would not tell of one more generous, more gentle, or more just. At the conclusion of the address, which was repeatedly cheered, the Royal visitors, who were received with every mark of respect, passed through the various wards of the hospital, and then took their departure.

#### CHOLERA IN RUSSIA.

THE latest advices state that cholera has declined at St. Petersburg, though it would appear to have increased at Moscow, and to be extending its ravages in a southward direction.

#### SANITARY STATE OF ILKLEY, YORKSHIRE.

ONE of the Privy Council Inspectors has recently been inquiring into the sanitary state of Ilkley, and, on account of the bad condition of the sewers and drains, has recommended that the attention of the Home Secretary of State should be called to the default of duty of which the Ilkley Local Board of Health has been guilty as to sewerage and as to the inspection and abatement of nuisances from sewers and drains. If this warning do not suffice to awaken the Ilkley Board to a sense of its public duty, we trust that not only will the attention of the Home Secretary be drawn to the matter, but that Mr. Bruce will see that all necessary steps are taken, either by the Board or by some one whom he shall appoint under the power given to him by the Sanitary Act.

#### BRITISH MEDICAL BENEVOLENT FUND.

AT the last monthly meeting of the Committee, grants to the amount of £90 were made to nine applicants for assistance; and one disabled member of the profession was elected to an annuity of £10, to qualify him for a vacant residence at Providence Place, Chippenham. The Treasurer reported an additional donation of £50 from Dr. Gull; and a warm vote of thanks was passed for this seasonable act of liberality.

#### CHOLERA AND SMALL-POX IN PERSIA.

CHOLERA is reported to have again made its appearance at Tehran and other places, and the deaths in Tehran have reached to ninety *per diem*. Small-pox is also stated to have been prevailing at Bushire, and to have caused the deaths of a large number of people during the months of March and April last; but it appears that the epidemic, if not now quite abated, is soon expected to be at an end.

#### CHOLERA IN MADAGASCAR.

CHOLERA has again made its appearance in Madagascar, and also in the French colony of Norse. In the latter place, it appears to have been very fatal; and many natives, and also some Europeans, appear to have fallen victims to it. We understand that precautions have been taken, and that the coast-trade has been stopped.

#### THE BROWN TRUST.

By the liberality of Mr. Cunliffe, who presented £2,000 for the purpose, the University of London has now been formally placed in possession of an excellent site and buildings at Battersea, and the Brown Institute for the Treatment and Study of the Diseases of Domestic Animals is now an accomplished fact. Thirty thousand pounds are available for the purpose. Dr. Burdon Sanderson, F.R.S., has been appointed by the Senate the first Brown Professor. This Institute will thus be placed in a position to render services alike important to humanity and to science.

#### THE MUSEUM OF THE ROYAL COLLEGE OF SURGEONS.

ONE of the most interesting features in connection with the annual election of Fellows into the Council of the Royal College of Surgeons is the very instructive collection displayed in the theatre of the additions about to be made to the museum, and which have been presented or purchased during the past year. One of the principal novelties in the osteological department is the skull of a very large sturgeon, in which all the cartilaginous portions, constituting the greater part, and which cannot be preserved by any known method in a condition suitable for ready examination, have been carefully modelled in soft wood, and the ossified portions fitted to them in their natural relations. The form of the brain-cavity, and the position, course, and size of the various nerve-apertures have been carefully reproduced by the ingenuity of Mr. James Flower, the articulator. The hippopotamus which was born in the Zoological Gardens in February last, and lived but two days, and which excited some interest as being the first of these animals produced in this country, has afforded an exceedingly good skeleton, valuable as showing the condition of development of the bones at that early period of life. The skeleton of the horse which had stood for many years in the Eastern Museum, frequently and erroneously designated as "Eclipse," has been replaced by a finer and more characteristic specimen, being that of the celebrated racer "Orlando," whose death occurred at the Royal Paddocks in December, 1868, at the age of 28. His remains were obtained for the museum with the permission of Her Majesty the Queen through the kind intervention of Mr. Sudlow Roots, of Kingston, a Fellow of the College. The additions to the pathological series have rather exceeded those of last year. Dr. Thurnam, of the Wilts County Asylum, has recently presented a collection of nearly fifty specimens, many of which are of considerable interest. The continuation of the revision of the Hunterian series of specimens of Physiology and Comparative Anatomy has occupied much of the time of the zealous conservator, Professor Flower. The whole of the division appropriated to the Nervous System and Organs of the Senses has now been put in perfect order. To 206 of the old preparations, 118 new ones have been added. The arrangement of the Dermatological Collection has been completed by the liberal donor; and a descriptive catalogue has been printed and published at the expense of Professor Wilson and presented to the College. Mr. Lowne is proceeding with the arrangement of the Teratological Collection, of which 164 of the preparations have been remounted. Mr. Taylor is engaged on a Supplementary Catalogue of the Calculi, which will shortly be added to the other valuable catalogues of the collection. The collection of Surgical Instruments and Appliances is making progress. Additions have been made to it by Messrs. Barrow, Barker, Birkett, Bond, White Cooper, Edwards, Holden, Kempthorne, Swan, Taylor, Wilson, and Mrs. Hatton. Amongst the contributors to the other series are the Zoological Society, the Royal Institution, Professor Gervais of Paris, Professor Van Beneden of Louvain, Professor Peters

of Berlin, Drs. Thurnam, Hickman, Reed, Fergusson, Prankerd, Cawther, Bennett, Hamilton, Sir William Fergusson, Messrs. Hilton, Quain, Cock, Partridge, Gay, Hancock, Spencer Wells, J. E. Adams, Hutchinson, Curling, Coleman, Flower, Slater, etc. The collection will remain on view in the theatre of the College until Thursday next, and will well repay a visit, containing, as it does, so many interesting and instructive cases.

#### THE VACCINATION ACT, 1867.

In answer to objections raised by Sir Massey Lopes, Mr. W. E. Forster said he could not admit that the working of this Act would make a large increase in the expenditure of the Poor-law guardians. As to the recommendations of the Select Committee—namely, “that a considerable proportion of the expenses of working the Act should be contributed from moneys to be voted by Parliament”—it had not been included in the Vaccination Bill, which was merely a Bill for the practical amendment of the Act to secure better provisions against the increase of small-pox. The recommendations of the Committee would require the serious attention of the Government, but the question of these expenses could not be considered by itself; it must be considered along with other subjects as between local rates and Imperial taxation.

#### BIRMINGHAM HOSPITAL FOR WOMEN.

THE staff of this new hospital was elected on Tuesday last, and is composed of Mr. C. J. Bracey, Mr. Savage, Mr. Ross Jordan, and Mr. Lawson Tait.

#### UNIVERSITY COLLEGE HOSPITAL.

DR. F. T. ROBERTS has been appointed Assistant-Teacher of Clinical Medicine. Mr. Berkeley Hill and Mr. Christopher Heath have been promoted from the office of Assistant-Surgeon to that of Surgeon. As teachers of practical surgery, they are introducing improvements into the course, destined to develop the completeness of the instruction and to meet the new requirements of the College of Surgeons.

#### THE KENT BENEVOLENT MEDICAL SOCIETY.

THIS excellent Society, which has been established more than two-thirds of a century, will hold its general meeting at the “Ship Tavern,” Greenwich, on Wednesday next, under the presidency of Dr. Carr, of Blackheath. It offers to all medical men actually resident in Kent at the time of joining, for the moderate sum of £1 1s. annually, the advantages of an insurance of considerable value, as well as those of a Friendly Society, to meet the special claims of sickness or disability, besides providing for widows and orphans. We strongly urge all the members of our profession in the county to join this Society.

#### GROWTH OF THE ASSOCIATION.

WE are very happy to see that, under the impulse of the activity of the energetic Honorary Secretary of the Lancashire and Cheshire Branch, Mr. Reginald Harrison of Liverpool, that Branch shows this year a total of 348 members—an increase of 52 since last year.

#### MEAT PRESERVING.

MANY methods have been introduced to meet the ever-growing want of England—cheap animal food. Some of these methods have been successful, and others the reverse. We could ill spare the little that is already placed at our disposal by Australian and other meat companies; and the highly remunerative character of investments in the preserved-meat trade affords a sure guarantee for greater efforts in the future than any that have hitherto been made. Laëg's process has been carried on very profitably at home as well as abroad; but the preparation of extract of meat has been declared wasteful from the small amount of stimulating material preserved, and the carting away of all albuminoid matters to the manure-heap. A new plan has been introduced by an engineer, whose experience in sugar refineries and other extensive works in hot latitudes has ensured a practical and economical solution of one of the most important problems of the day. Mr. T. F. Henley does

away with steeping meat in water, and with boiling and otherwise treating it in the most costly way. He simply squeezes a definite amount of juice out of the fibre, and by mechanical desiccation preserves the latter intact. The pressed meat thus obtained contains ten per cent. of alcoholic extract and salt, and over fifty per cent. of fibrin and other albuminoid constituents. It is exceedingly rich, and so is the meat-juice which Mr. Henley evaporates in vacuum-pans. The juice contains about fifteen per cent. of alcoholic extract, and over fifty per cent. of albumen. The ancient method of abstracting water only from the animal matter is relied on as the preservative, and the low temperature at which the evaporation is carried on prevents any loss of flavour or other deterioration. It is perhaps strange that so cheap and simple a process should not have been suggested before. Mr. Henley has worked at it for some time, and perfected it so as to ensure its immediate adoption. The first works, on an extensive scale, are to be opened in the River Plate, on the Estancia Nueva Alemania, where cattle have been reared and fattened for the European markets. It is proposed to slaughter three hundred bullocks daily; and since it is stated that the hides and feet pay the first cost of the bullock and of its slaughtering, the financial prospects of the undertaking wear a promising aspect.

#### THE GERMAN ARMY SURGEONS AND THE WAR.

A STATISTICAL report published by the Medical Department of the Prussian Ministry of War states that, during the recent war with France, 101 surgeons of the Prussian army died, or were disabled for a long time by wounds. Of these, six fell on the field of battle, and three died of the results of their wounds. Besides these, sixty-three received gunshot wounds—two of them each twice. Twenty-five surgeons died of disease; four of them from dysentery, eight from typhoid fever, and one from a combination of the two diseases. The number of army medical officers in the Prussian army who died of typhoid and dysentery is very small in proportion to those who fell victims to epidemic diseases in the Crimean war.

#### THE PHARMACY BILL.

IN answer to Mr. T. Cave this week, Mr. W. E. Forster said that the Government intended to proceed with this Bill during the present session, its object being mainly to ensure that the first clause of the Pharmacy Act, passed in 1868, which said there should be regulations for the keeping, dispensing, and selling of poisons, should be complied with. He was aware that several petitions had been presented against the Bill from chemists and druggists throughout the country; but he hoped to be allowed to take the second reading on Thursday, with a view afterwards to go into Committee *pro forma* and reprint the Bill with amendments, which he believed would meet the wishes of many persons connected with the trade.

#### THE ANNUAL MUSEUM, 1871.

WE beg to call the attention of our readers to the proposed scheme of our Annual Museum at the Plymouth meeting. In addition to pathological specimens, casts, drawings, new medicines and articles of diet, and new books, deposited for examination by the members and description in the JOURNAL, it is proposed to make a special collection of diagrams and instruments setting forth the history, from the earliest records down to the present time, of appliances used in a special branch of surgery, namely, in the treatment of fractures. Many such are novel to the great majority which are known to the few; and their interest may be either of rarity, or of antiquity, or of special application, as well as of absolute newness. We may suggest that possibly some of those who exhibit may subsequently desire to add their objects and photographs for permanent display in the collection of surgical instruments which, at the instance of Sir William Fergusson, it is proposed to make at the Royal College of Surgeons, London. We should be pleased to find our Annual Museum helping to swell the means for the permanent instruction of the profession in this way.

## SCOTLAND.

WE hear that Dr. Marshall, the able and popular practitioner at Braemar, is about to leave that locality to fill a permanent appointment in the Royal Household.

## MUNIFICENT DONATIONS.

MR. JOHN FREELAND, of Nice, has, it is stated, given £3,000 to the Glasgow University, £5,000 to the Royal Infirmary, and £5,000 to the Andersonian Institution.

CRAIG *versus* JEX BLAKE.

THE first division of the Court of Session has sustained Lord Mure's ruling, and disallowed the bill of exceptions. Expenses were accordingly granted to the pursuer.

## EDINBURGH: THE SECOND SIEGE OF THE UNIVERSITY.

THE ladies have again laid siege to the University of Edinburgh, and apparently with promise of better success than attended the defensive efforts of the Amazons of the second siege of Paris. The circumstances which have given rise to this renewal of hostilities, are the following. Two years since, the University sanctioned the study of medicine by women, and admitted them to matriculation as medical students. During the subsequent period, Miss Jex Blake and four other ladies have completed the first half of their University course. It appears that by application to the several professors whose courses it is necessary for them next to attend, they cannot obtain from them the requisite instruction during the ensuing winter session, as these professors are not prepared to deliver second courses of lectures for the benefit of the ladies, and they are debarred by the existing regulations from obtaining qualifying instruction in the University in any other way. They are, at the same time, it is stated, prevented from obtaining the necessary classes in the extramural school, as they have already attended four classes outside the University, and the general regulations do not allow University students to exceed this number. Under these circumstances, Miss Jex Blake now addresses the Senatus on behalf of the lady medical students, and requests that they will take into immediate consideration what steps may be necessary to enable them to complete the education that they have already carried so far in the University of Edinburgh. In doing so, she submits two suggestions: 1. That whenever a professor may be unable or unwilling to deliver a separate course of lectures on his subject, the Senatus should nominate, for the approval of the University Court, a special lecturer on the said subject, for the express purpose of giving the requisite qualifying instruction, the ladies undertaking to defray the expenses of such appointment: 2. That the University regulations with respect to extramural classes should be so far relaxed in their special case that, whenever a professor may be unable or unwilling to deliver a separate course of lectures, they should be authorised to attend a corresponding class on the same subject in the extramural school, the said class being held to qualify equally for graduation. The matter was brought up for discussion at a meeting of the Senatus on Friday of last week, but it was decided to postpone the full consideration of the subject until legal advice had been obtained as to the powers of the Senatus in dealing with the suggestions contained in Miss Jex Blake's letter. We presume that the Senatus of the University, if they are found to have not sufficient legal authority in the matter, might, if they were favourable to the carrying out of either suggestion, obtain with little difficulty the necessary powers; so that the result of the petition rests largely in the decision of the members of the Senatus. The schemes suggested by Miss Jex Blake are both apparently feasible, and cannot be accused either of entailing inordinate labour on the professors or of necessitating mixed classes, to which many members of the Senatus are opposed.

## IRELAND.

THE Medical Travelling Prize in the School of Physic of Trinity College, Dublin, value £50, has been awarded to Mr. Jacob O'Connor.—No Surgical Travelling Prize has been awarded this year.

## LUNACY LAW IN IRELAND.

SIR DOMINIC CORRIGAN has introduced in the House of Commons a Bill to amend the law relating to dangerous lunatics and dangerous idiots, and to make more effectual provision for the superannuation of the officers of District Lunatic Asylums in Ireland. The clauses are as follows.

1. It shall be lawful for any two justices causing any person to be examined by a medical officer under the provisions of the said recited Act of the thirtieth and thirty-first Victoria to call to their assistance the medical officer of the dispensary district as provided for under the said recited Act, or any other legally qualified medical practitioner, and to make an order under their hands and seals upon the governors of the lunatic asylum established either wholly or in part for the county, county of a city, or county of a town in which such person shall have been apprehended, for the payment to such medical officer or other legally qualified medical practitioner called to their assistance of such reasonable remuneration for the examination of any such person, and for the payment of all other reasonable expenses in or about the examination of any such person, as may have been incurred by such medical officer, not exceeding in the whole the sum of *two pounds two shillings*, and such justices may make such order for payment, whether such person so examined shall or shall not be certified by such medical officer to be a dangerous lunatic or a dangerous idiot, as the case may be.

2. It shall be lawful for the governors of any district lunatic asylum in Ireland, with the approval of the inspectors of lunatics, or one of them, to direct that any officer who has served for above twenty years at the least, and who is incapable from age, infirmity of mind or body, or otherwise, of discharging the duties of his office, shall be superannuated, and shall receive such yearly superannuation pension as upon consideration of all the circumstances of each case shall appear just, not exceeding such proportion of his salary and allowances as hereinafter mentioned; that is to say, for above twenty years service, a pension not exceeding two-thirds of his salary.

3. The several moneys to be paid or to become payable under this Act shall respectively be advanced, paid, presented for, and raised in like manner as any other moneys advanced or raised for supporting and maintaining such asylums.

## THE SOLUTION OF A DELICATE QUESTION.

AN animated correspondence is published in the Dublin papers between a dignitary of the Roman Church and Drs. Beatty, Churchill, and McClintock, on the effort which is being made to introduce sectarian principles into the election of dispensary medical officers. The Rev. Canon urges that craniotomy is, under any circumstances, detestable in the eyes of Roman Catholics. The answer, of course, is, that the sole object of medical men is to fulfil their sacred duty of saving life. It rests with the patient or the patient's friends to prohibit proceedings having that object, on the ground of opposing religious or other convictions, if they entertain them. A Roman Catholic patient entertaining a settled objection to craniotomy under any circumstances would, perhaps, on the whole, be in a better position under the care of a Protestant surgeon, bound by all the rules of his profession to respect the expression of those convictions, than a Protestant patient would be, needing and willing to benefit by the proceedings, under the care of a Catholic surgeon, whose scruples of conscience should prevent him from proposing it. This is, however, to put an extreme case. We earnestly deprecate the introduction of the element of dogmatic strife into medical elections, or in the appointment of officers whose duties need never, under any circumstances, place them in opposition to religious opinions of any kind.

## ASSOCIATION INTELLIGENCE.

### BRITISH MEDICAL ASSOCIATION: ANNUAL MEETING.

THE Thirty-ninth Annual Meeting of the British Medical Association will be held in Plymouth, on Tuesday, Wednesday, Thursday, and Friday, the 8th, 9th, 10th, and 11th of August next.

*President*—E. CHARLTON, M.D., D.C.L., Physician to the Newcastle-upon-Tyne Infirmary.

*President-elect*—JOHN WHIPPLE, Esq., F.R.C.S., Consulting Surgeon to the South Devon and East Cornwall Hospital.

An *Address in Medicine* will be delivered by GEORGE JOHNSON, M.D., F.R.C.P., Professor of Medicine in King's College, London.

An *Address in Surgery* will be delivered by JOSEPH LISTER, Esq., F.R.S., Professor of Clinical Surgery in the University of Edinburgh.

*Notices of Motion*.—The following notices have been given.

THE PRESIDENT OF THE COUNCIL : Rule 4. To insert "President-elect", and to omit "Secretary".—Rule 6. To expunge this rule, and to substitute the following: "Each retiring President of the Association and President of Council shall be appointed a Vice-President for life by a vote of the members at the Annual Meeting".—Rule 7. To add "the Vice-Presidents" after President-elect; to insert the word "and" between President of the Council and Treasurer, and to erase "and the Secretary".—Rule 8. In this and every rule where "District" is prefixed to Branch, to erase the word "District", and to erase the words "the Secretary of the Association".—Rule 9. To omit the words between "The President of the Council" and "shall be elected".—Rule 10. To omit the words between "The Treasurer" and "shall be elected".—Rule 11. To erase the words after "There shall be one paid Secretary" in first section, and to substitute "who shall reside in London, and devote his whole time to the business management of the Association and of the JOURNAL office". To erase the words "otherwise" in seventh line and "an annual or special" in eighth line, and to insert "each Annual Meeting".—Rule 13. To erase the words "Secretary shall call", and to substitute "President of Council shall direct to be called".—Rule 14. Between "shall" and "be recommended", to insert "express his desire in writing, and shall be".—Rule 15. To add "Members may be admitted on and after July 1st in each year, and the subscription for such part of a year shall be half a guinea". To erase the words after "each member" in eighth line, and to substitute "as long as his subscriptions remain unpaid, provided due notice shall have been given of such withholding".—Rule 16. To erase the words after "from his" in fourth line, and to substitute "liabilities to the Association".—Rule 24. In tenth line, to insert "a copy of the laws" between "Association" and "and".

Dr. STEELE (Liverpool): Election of Committee of Council. Every associate, who is a member of the Council, and desirous of a seat on the Committee of Council, shall send to the General Secretary, not later than months prior to the Annual Meeting of the Association, a declaration signed by himself, and in the following terms: "I, A. B., of C., member of the British Medical Association, hereby declare that I am a candidate for a seat on the Committee of Council of the said Association. (Signed) ———." Together with a nomination-paper signed by six members of the Association, in the following terms: "We, the undersigned, members of the British Medical Association, certify that A. B., of C., is a fit and proper person to be a member of the Committee of Council of the said Association." The names of the eligible candidates, with the names of the six associates by whom they shall have been respectively nominated, shall be published in the BRITISH MEDICAL JOURNAL not later than months prior to the Annual Meeting of the Association.

Mr. NICHOLSON (Hull): To alter Law 16, line 2. For "three", insert "two".

Dr. WATKIN (Birmingham): In Law 8, Paragraph No. 3, of the duties of Council, to alter "ten" into "twenty-five"; and to omit the words "and one Secretary from each Branch".

Gentlemen desirous of reading papers, cases, or any other communications, are requested to give notice of the same to the General Secretary at their earliest convenience.

T. WATKIN WILLIAMS, F.R.C.S., *General Secretary*.

13, Newhall Street, Birmingham, June 13th, 1871.

### THE ANNUAL MUSEUM.

THE "Annual Museum" of this Association will be open during the four days of the meeting, for the exhibition of:

1. The latest inventions in medical and surgical instruments and appliances of every kind. Also, for the special exhibition of ancient and modern fracture apparatus, or diagrams of such, thus setting forth the history of the treatment of fractures from the earliest records down to the present day.
2. New drugs and their preparations.
3. New articles of diet for invalids.
4. Pathological Specimens; also photographs, casts, etc., illustrating disease.
5. New works on medicine, surgery, etc.
6. Models or drawings of any object of professional interest not included in the above list.

*Notice to Exhibitors*.—Application should be made as soon as possible; at the same time giving a list of the objects to be exhibited, and mentioning the space required. All objects sent must have a description attached. Parcels for the Museum should be addressed—"British Medical Association, the Assembly Rooms, Plymouth; care of H. Greenway, Esq." They must be delivered on or before July 31st, and be removed within three days after the termination of the meeting. Expenses of carriage and all risk must be borne by the exhibitors. A card, bearing the name and address of the exhibitor, must be enclosed in each package, ready to be fixed on the outside. All communications respecting the Museum to be addressed to "Henry Greenway, Esq., Surgeon, Plymouth", the Secretary for that department.

### THE PROPOSED ALTERATIONS IN THE LAWS.

In the statement of the proposed alterations in the laws, at page 22 of last week's number, Mr. Nicholson's proposal for altering the word "three" to "two", was by error applied to Law 14. It belongs to Law 16; which, with its alterations, should be read as follows.

16. The name of no member shall remain on the books of the Association, whose arrears extend over [three] [two]\* years; but the omission of the name from the list of members shall not be deemed, either in honour or equity, to relieve any member from his [liability for the subscriptions due for the period during which he has availed himself of the privileges of membership] [liabilities to the Association].

The fourteenth law, with its proposed alteration, will then stand thus.

14. *Admission of Members*.—Any qualified medical practitioner, not disqualified by any bye-law, who shall [express his desire in writing and shall] be recommended as eligible by any three members, shall be admitted a member at any time by the Committee of Council, or by the Council of any Branch; provided he shall have the votes of three-fourths of those present.

### CUMBERLAND AND WESTMORLAND BRANCH.

THE third annual meeting of the above Branch will be held at the Bush Hotel, Carlisle, on Wednesday, July 12th, at 1 o'clock. *President*, Dr. L'ANSON, Whitehaven; *President-elect*, Dr. ELLIOT, Carlisle. Dinner will be provided at 4.30, at the usual charge.

Gentlemen having papers or cases to communicate, will greatly oblige by sending early intimation to

HENRY BARNES, M.D., *Honorary Secretary*.

Carlisle, June 20th, 1871.

### BATH AND BRISTOL BRANCH.

THE annual meeting of the above Branch will be held on Thursday, July 13th, 1871, at the Institution at the top of Park Street, Bristol, at 4.45 P.M.

Members having any communications for the meeting are requested to give notice of them to the Secretaries.

The dinner will be held at the Royal Hotel, College Green, Bristol, at 6.30 P.M. Dinner tickets, including ice and dessert, 7s. 6d. each. Wines at moderate charges.

E. C. BOARD, Clifton, } *Honorary Secretaries*.  
R. S. FOWLER, Bath, }

### NORTHERN BRANCH: ANNUAL MEETING.

THE Seventh Annual Meeting of this Branch was held in the Assembly Room, Tynemouth, on Thursday, June 15th: J. B. BRANWELL, M.D., *President*, in the Chair. There were also present thirty-one members, and three visitors.

\* Mr. Nicholson.

The PRESIDENT, having thanked the meeting for the honour they had conferred upon him, and referred to the healthiness of Tynemouth, said that during the twenty-seven years he had been in practice in Tynemouth he had witnessed two severe epidemics of cholera and one of typhoid fever, several of small-pox, and many of scarlet fever and measles. One disease (typhus) frequently endemic in some towns, was only an occasional visitor in the borough of Tynemouth; and then its origin could always be traced to direct importation, and rarely had he known it to spread beyond a few cases. Had Tynemouth possessed a fever hospital, with power to enforce the removal of any important case, the town might have been kept entirely free from the disease. He described the origin and causes in the borough of the epidemics alluded to. Speaking of the small-pox epidemic, he said it was not his intention to say anything on the subject of vaccination generally, as he believed the members were fully persuaded of the power possessed by vaccination of controlling the disease. He would merely state that the conclusions drawn by him in private practice were in exact consonance with those derived from hospital statistics. He had never seen a fatal case of small-pox in any one that he had himself vaccinated, nor had he ever seen the disease spread in any family where revaccination was at once practised. His conclusion was that efficient vaccination enforced by law, with revaccination, would effectually eradicate the disease from the kingdom. The only reasonable objection to such law was the now admitted fact that syphilitic poison had in a few cases been conveyed into the system with vaccine lymph; but these cases were so few that he was not of opinion that an evil so infinitely small, and which itself could be guarded against, should influence us in enforcing this most important protection on all. With regard to other epidemic diseases, there were not as yet any protectives like vaccination; but each case should be reported to a duly appointed central authority, empowered to enforce isolation or removal as might be deemed best to prevent the formation of a focus or centre of infection, and to prevent the convalescent from speedily mixing with the healthy. He referred more especially to scarlet fever; and he thought it should be made penal for any teacher to receive a child who had suffered from that disease back to school until authorised by a medical certificate. If the registration of infectious disease could be made compulsory, it would be a great step in advance. He believed it to be of great importance that members of societies like the Branch should form definite opinions on the most likely means to control the ravages inflicted by epidemic diseases, and that they should privately, amongst their friends and patients, and publicly, when opportunity offered, disseminate their views, and thus lead the Legislature to pass the necessary laws to render them effectual. The President then read a statement by Dr. Philipson, showing that the number of members of the British Medical Association was 4,258; that, in 1865, the numbers of members of the Northern Branch was 53, and was now 235; that during last year there had died of members of the Northern Branch 12, resigned 10, and that the new members numbered 23.

Mr. BROADBENT (Hetton) moved a vote of thanks to the President for his able address.—Dr. TESSIER seconded the proposition, and spoke strongly in favour of vaccination and revaccination.

*Vote of Thanks.*—Dr. FOTHERGILL (Darlington) proposed—"That the warmest thanks of the meeting be awarded to the retiring President (George Welford, Esq.), the Council of Management, and the other officers for their services during the past year." This was seconded by Mr. HEFFERNAN (Spenny Moor), and carried by acclamation.

*Officers for 1870-71.*—On the motion of Dr. EASTWOOD, seconded by Dr. JONES, it was unanimously resolved—"That the next Annual Meeting be held at Stockton-on-Tees; that Charles Trotter, [Esq., F.R.C.S., be President-Elect; Dr. Philipson, Honorary Secretary and Treasurer; Dr. Charlton, Dr. Tessier, Dr. Frain, and Dr. W. H. Dixon, the Council of Management."

*Representatives in the General Council.*—On the motion of Mr. W. R. SHIELL, seconded by Mr. W. H. SMITH, the following members were elected to represent the Branch in the General Council of the Association: G. Y. Heath, M.D.; Charles Gibson, M.D.; J. B. Bramwell, M.D.; Martin Burnup, M.D.; R. J. Peart, M.D.; Robert Wilson, M.D.; John Jobson, Esq.; George Welford, Esq.; S. W. Broadbent, Esq.; H. G. Hardy, Esq.; Charles Trotter, Esq.; J. W. Eastwood, M.D.; and G. H. Philipson, M.D., *en officio*.

*Representative in the Parliamentary Committee.*—It was moved by Mr. R. H. B. WICKHAM, seconded by Mr. BYROM BRAMWELL, and unanimously agreed to—"That Dr. Philipson be the representative of the Branch in the Parliamentary Committee."

*Treasurer's Report.*—Dr. Philipson read the Treasurer's statement, which showed that the balance in hand, at the commencement of the year 1870, was 12s. 1d., and the amount received in annual subscriptions was £28 4s.—total, £28 16s. 1d. The expenses during the year

amounted to £28 6s. 10d., leaving in December 31st, 1870, a balance of 9s. 3d.

*Cases.*—1. Dr. LEGAT introduced a boy upon whom he had performed Double Amputation above the ankles; also, a successful case of operation for Imperforate Anus.

2. Mr. C. T. JEAFFRESON exhibited and explained several beautifully drawn diagrams of the Fundus of the Eye.

3. Dr. PHILIPSON exhibited a specimen of Recurrent Fibroid Tumour, which he had received from Mr. R. T. Lightfoot.

*Papers.*—The following papers were read:—1. On the recent and still prevailing Epidemic of Small-Pox at South Shields; with special reference to the origin, spread, and treatment of the disease. By Andrew Legat, M.D.—2. On the Hectic State in Phthisis Pulmonalis. By R. W. Foss, M.B.—3. Notes of a case of Incipient Dementia, with observations on the diagnosis and treatment. By R. H. B. Wickham, F.R.C.S.Ed.—4. Case of Hydrophobia. By J. W. Eastwood, M.D.—5. Case of Hydrophobia. By J. R. Fothergill, M.D.

On the motion of the President, a hearty vote of thanks was accorded to the readers of the papers, with the expression of the hope that they would allow them to be published in the BRITISH MEDICAL JOURNAL.

*Dinner.*—The members and their friends afterwards dined together at the Bath Hotel, the President (Dr. Bramwell) in the chair, supported by the Mayor of Tynemouth (George Bell, Esq.), the Vicar of Tynemouth (Rev. Thomas Brutton, M.A.), the President of the British Medical Association (Dr. Charlton), Dr. Negus, of H.M.S. *Castor*, and Dr. Parker Smith, H.M. 35th Regiment, etc.

#### EAST ANGLIAN AND CAMBRIDGE AND HUNTINGDON BRANCHES: ANNUAL MEETING.

THE members of the East Anglian and Cambridge and Huntingdon Branches of this Association held their annual meeting at the Norfolk and Norwich Hospital on Friday, June 30th, under the Presidency of Dr. EADE of Norwich. There were also present fifty-five members and visitors, and the pupils of the Norwich Hospital. After the members and visitors had partaken of an elegant luncheon, given by the medical and surgical staff of the hospital, they commenced the business of the meeting in the Harrison Ward.

Dr. CHEVALLIER, the late President, made a few introductory remarks, and then introduced Dr. Eade, the President for this year, who delivered an inaugural address.

Dr. PITT, Honorary Secretary, read the report of Council, which congratulated the members in again assembling in Norwich, and expressed satisfaction with the manner in which the JOURNAL is conducted, and at the gradual increase of members.

The following resolutions were then passed.

1. Proposed by Dr. DURRANT and seconded by Mr. FAIRCLOTH—"That the thanks of this meeting be given to retiring President, Members of Council, and Honorary Secretaries, for their services during the past year."

2. Proposed by Dr. HUMPHRY and seconded by Mr. MURIEL of Ely—"That the Members of the Council and Honorary Secretaries be re-elected."

3. Proposed by Dr. COPEMAN and seconded by Mr. CADGE—"That the next annual meeting of the East Anglian Branch be held in conjunction with the Cambridge and Huntingdon Branch at Ely, and that R. Muriel, Esq., of that city be elected President."

*New Members.*—Mr. H. Robinson, Norwich; Mr. P. Ransom, North Elmham; Dr. C. D. H. Drury, Pulham St. Mary; and Mr. Thomas Garney, Bungay, were elected.

*Papers.*—The following papers were then read. 1. Reminiscences of Surgery in the Norwich Hospital Five-and-Thirty Years Ago, by G. M. Humphry, M.D., F.R.S. This elicited considerable discussion by Dr. Bateman, Dr. Copeman, Mr. Cadge, Mr. Reade, Mr. Brownfield, Mr. Muriel, and Mr. G. Taylor.—2. Pre-Phthical Dyspepsia, by C. M. Durrant, M.D. A discussion followed, in which Mr. Allen and Dr. Bateman took part.—3. Ovariectomy, by W. Cadge, Esq. The paper caused considerable discussion by Professor Humphry and others.—4. Accidents in Lithotomy, by T. W. Crosse, Esq. Dr. Eade and Mr. Pringle took part in the discussion.—5. Intraocular Malignant Growths, by H. Robinson, Esq. Papers from Drs. Bateman, Bradbury, and Lowe, were omitted for want of time.

A *Vote of Thanks* to the President was proposed by Mr. FAIRCLOTH, and the meeting separated.

*Dinner.*—The members and friends, including the Mayor of Norwich and the Rev. G. Cook, Vicar of Worstead, and numbering forty-one, dined together at the Norfolk Hotel; Dr. Eade occupying the chair, and Dr. Pitt the vice-chair.

## SOUTH MIDLAND BRANCH: ANNUAL MEETING.

THE fifteenth annual meeting of this Branch was held at the Northampton General Infirmary on Tuesday, June 27th. There were present, W. W. CLARK, M.D., President, in the chair, and eighteen members and visitors.

*New Member.*—Dr. James More, of Rothwell, Northamptonshire, was duly elected.

*Officers and Council.*—The following were elected. *President-elect*, Allan D. Mackay, M.B. *Honorary Secretary and Treasurer*, John M. Bryan, M.D. *Joint Honorary Secretary*, W. Moxon, Esq. *Committee of Management*: F. Buszard, M.D.; C. J. Evans, Esq.; A. Evershed, Esq.; G. P. Goldsmith, Esq.; J. H. Hemming, Esq.; C. E. Prior, M.D.; R. W. Watkins, Esq.; E. Woakes, M.D. *Representatives in the General Council*: R. Ceely, Esq.; D. J. T. Francis, M.D.; A. D. Mackay, M.B.; H. Terry, jun., Esq.; R. W. Watkins, Esq. *Representative in the Parliamentary Committee*: J. M. Bryan, M.D.

*Proposed Conjoint Meeting.*—Mr. HEMMING proposed, and Dr. W. CLARK seconded—"That a joint meeting of the Cambridge and Huntingdon Branch and the South Midland Branch be held at Huntingdon or Peterborough in 1873." The consideration of the subject was deferred to the autumnal meeting of the South Midland Branch.

*Corresponding Secretaries.*—Mr. ASHDOWN proposed, and Mr. KNOTT seconded, the appointment of a corresponding secretary for each of the three counties of Bedford, Buckingham, and Northampton.

*Autumnal Meeting.*—Mr. MASH proposed, Mr. WATKINS seconded, and it was resolved—"That the autumnal meeting be held at Wellingborough."

*Report.*—Dr. BRYAN, the honorary secretary, read a report, in which he mentioned the continued success of the Branch, both in numbers and funds, and referred to the Parent Association, numbering only 2,500 six years since, and now over 4,250, with additions in prospect. Within the last twelve months, seven members had left the district or had resigned. Two had died; viz., Mr. Thurnall of Bedford, and Mr. Lambden of Rippingale. Since the last annual meeting of the Branch, Dr. Bryan, in his capacity of its representative, had attended several meetings of the Committee of Council of the Parent Association held in Birmingham and in London. The principal business discussed had been the financial affairs; and it was proposed to alter several of the laws of the Association, which, it was hoped, would thereby be placed on a firmer basis, and also to have the General Secretary resident in London, with full control over the office management, which he had not had hitherto. It had been also decided that applications for subscriptions should be made by the secretaries of Branches four times in the year; viz., January, April, July, and October, after which accounts were to be given up to the General Secretary. It was, however, hoped that members would send their subscriptions to the secretaries or treasurers of Branches in the first month in the year, and thereby prevent the necessity of frequent applications. On December 31st last, the subscriptions of five members of the Branch remained unpaid; and those of twenty-four at the present time (June 27th).

*President's Address.*—Dr. CLARK read an address.

*Papers.*—The following were read. 1. Case of Scarlatina in an adult, followed by temporary Blindness: Recovery. By A. D. Mackay, M.B. 2. Case of Belladonna Poisoning. By J. G. Carruthers, Esq. 3. Case of Intussusception: Recovery. By Arthur Evershed, Esq. A portion of intestine, including the caecum with its appendix and ileum—altogether a yard—sloughed and came away. The patient, a youth, aged 15 or 16 years, ultimately recovered, and is now alive and well. 4. Notes on some Antipyretic Remedies; viz., Cold Affusion, Belladonna, Acetate, etc. By W. Newman, M.D. In Dr. Newman's absence, this paper was read by the President. A paper by Dr. Woakes on a successful case of Ovariectomy was not read on account of want of time and the absence of the author.

*Alteration of Rules of Branch.*—Mr. ASHDOWN gave notice of a proposal that a luncheon only and no dinner should be had at future meetings.

*List of Thanks* was passed to Dr. Clark, the President; to the authors of papers; and to Dr. Bryan, the Honorary Secretary and Treasurer.

*Dinner.*—The members and visitors dined together at the George Hotel.

## REPORTS OF SOCIETIES.

## ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, JUNE 13TH, 1871.

T. B. CURLING, ESQ., F.R.S., PRESIDENT, IN THE CHAIR.

ON THE REMOVAL OF TUMOURS FROM BONES.

BY JAMES PAGET, D.C.L., F.R.S.

THE design of the paper was to show the propriety of removing the majority of non-malignant tumours growing in bones, by simple extirpation or enucleation, rather than by resection of the bones or by amputation. It was shown that these tumours are as separate from the proper tissue of the bones as are fatty and most other innocent tumours from the connective tissue or other structures in which they grow; and that the same rules of operation are applicable to the one as to the other set of tumours. Cases were given of successful enucleation of fibrous, myeloid, cartilaginous, and osseous tumours, and some rules were stated for the diagnosis of malignant from innocent tumours in bones, and of those which grow within from those which grow without the bones.—After a few remarks by Mr. FAIRLIE CLARKE on the great value of Mr. Paget's paper, Mr. BIRKETT remarked that the same practice as that recommended by the author had been for years adopted at the London hospitals; certainly at Guy's Hospital, especially in tumours of the jaw. He referred, among other cases, to one of myeloid disease of the radius, which was enucleated many years ago by Mr. Bransby Cooper, but which returned and necessitated amputation. The patient was still living, but the case showed that enucleation may not be sufficient to eradicate the disease.—Mr. THOMAS SMITH related a case of a tumour of the size of a fist at the head of the humerus in a female, aged 22. It had existed for two years: it pulsated and enlarged, and the general health was suffering. There was no gland-enlargement. Mr. Paget recommended enucleation, which was done, but not thoroughly. The wound closed, and the patient recovered very fair use of her arm, but at the end of the year the growth returned. At the second operation, she died of pleuropneumonia.—Mr. BIRKETT, in answer to Mr. Smith, said that in such a case he would have performed the same operation.—Mr. WEEDEN COOKE had found it necessary in some cases to amputate, as enucleation was impossible.—Dr. O'CONNOR related a case bearing on the discussion.—Mr. SAVORY considered that the value of the paper rested on the information given as to the kind of tumours to be enucleated. He thought that strumous or scrofulous disease of bone might also be treated on this great principle, as in the tarsus. Some surgeons believed that the disease was afterwards made worse by the irritation caused by the operation; but still, if the disease were thoroughly removed, he thought it would be found to be successful.—Mr. JOHN CROFT alluded to a case illustrating Mr. Paget's paper.—Mr. PAGET, in reply, said that he was quite conscious that the treatment was often done, but he wanted to see it more generally adopted. The difference lay between enucleation and resection of bone, and not, as Mr. Birkett said, between enucleation and amputation.

A FOURTH SERIES OF ONE HUNDRED CASES OF OVARIOTOMY, WITH REMARKS ON THE DIAGNOSIS OF UTERINE FROM OVARIAN TUMOURS. BY T. SPENCER WELLS, F.R.C.S. ENG.

Following the order of former papers, the author had arranged this fourth series of one hundred cases in tables of three series.

Series 1. Cases in which ovariectomy was completed—100 cases: 78 recoveries, 22 deaths.

Series 2. Cases in which ovariectomy was commenced, but not completed—6 cases: 2 relieved or cured, 4 died.

Series 3. Cases where an exploratory incision was made—7 cases: 5 recovered from incision, 2 died.

He showed that the mortality after ovariectomy was steadily diminishing. Of his first 100 cases, 34 died; of his second 100 cases, 28 died; of his third 100 cases, 23 died; and of his fourth 100, 22 died. In this fourth series, 44 had been in hospital, and 56 in private practice. In private practice the mortality was only 14 per cent., while in hospital it was 31 per cent. The author believed that the mortality in private practice might be taken as a guide to what might become the general average mortality after ovariectomy, and he was convinced that it might be reduced to about 10 per cent. without excluding those extreme cases where the operation was performed as a forlorn hope. The author then proved that large tumours of the non-gravid uterus had been frequently mistaken for ovarian tumours; and he pointed out how they might be distinguished from each other. He showed that there was nothing in the history of a doubtful case which afforded any very decisive assistance, and then examined in detail the signs afforded by inspection and measure-

ment of the abdomen, by palpation, and by percussion and auscultation, which are of value in diagnosis. He then described the conditions to be observed in examination by the vagina and rectum—alone or combined—and in conjunction with examination by the abdominal wall; deferring to a future opportunity any account of the results obtained by exploratory puncture or incision.—Dr. WEST, in paying a tribute to Mr. Wells for his great services as an ovariologist, remarked that the papers which were most open to discussion were not always the papers of most value. He believed that we should fall into very few errors if we followed out the precautions given in the paper by Mr. Wells. The operation was a great boon to society. Every chance should be given to enable the patient to recover, on which the success of the most skilful operator so much depended.—Mr. SPENCER WELLS, in replying, exhibited a fibroid tumour of the uterus weighing eleven pounds eleven ounces, which he had removed on the previous day by the *écraseur* after incision. There had been a considerable quantity of fluid in the abdomen, which he had drawn off; but, as it again speedily collected, he determined to remove the tumour. There was some bleeding from the pedicle, which was necessarily transfixed by needles. The patient was doing well.

## OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, JUNE 7TH, 1871.

J. BRAXTON HICKS, M.D., F.R.S., President, in the Chair.

MR. C. R. CARTER exhibited a large Uterine Fibroid Tumour, removed after death. In its interior were contained about three pints of pus.

Mr. SCOTT exhibited two Ovarian Tumours removed from a patient aged 35. The one was a multilocular cyst of the right ovary, the other a fibroid tumour of the left ovary. The operation had been performed on the 3rd of May, and the patient was progressing favourably.

Dr. GREENHALGH exhibited his new Metrometer Sound for measuring any part of the cavity and neck of the uterus from side to side, and from back to front, as well as in its long axis.

Dr. MEADOWS read a paper on Pelvic Hæmatocele, with special reference to its diagnosis and treatment. He expressed his conviction that this affection, though not common, is not so rare as is generally supposed; nor in many cases is the diagnosis a matter of much difficulty, though very puzzling in some and especially in the less severe forms, or when seen long after the attack. Allusion was made to a paper by Dr. Barnes on Intraperitoneal Hæmorrhage, published in the last number of the *St. Thomas's Hospital Reports*. The author criticised some of the cases in regard to their diagnoses, and expressed some doubt as to their accuracy in this respect, judged solely by the details given. An examination of these cases in their results when compared with others of the same kind, collected from the works of MM. Bernutz and Goupil, showed that of 40 cases of the former, three only died; whereas, in 62 cases of the latter, only eighteen recovered. In regard to diagnosis, difficulties were greatly lessened in cases where the attendant knew the exact condition of the parts before the occurrence of the attack; because, as swelling necessarily resulted from the hæmorrhage, its absence before the attack and its immediate discovery afterwards, together with the attendant symptoms, pointed at once to the nature of the case, inasmuch as no other swelling occurred thus suddenly. The differential diagnosis of uterine displacements; of tumours, either of the uterus or of the ovaries, becoming suddenly impacted in one or other *cul-de-sac*; of pelvic cellulitis; or of pelvi-peritonitis, was dwelt upon at some length, and their distinctive features were pointed out. The author recommended the division of the cases into two groups; the first to include all those which originated in the performance of the functions of menstruation or parturition; and the second, those of distinctly organic origin, not connected directly with the uterine functions. He advocated more frequent resort to puncture, grounding his recommendation on the fact that of Bernutz's eighteen cases which recovered, nine were operated upon, seven ruptured spontaneously, and only two were left alone; while of twelve fatal cases, two only were tapped, one ruptured spontaneously, and nine were left alone. The author related two cases in which he had tapped successfully, and the paper ended with some directions as to the conditions, mode, and time, of operating.—Dr. BARNES said that Dr. Meadows doubted his cases because they were so many; but was his experience so exceptional? Olshausen said that, in 1867, Scanzoni had only seen two cases, but that he ought to have seen 200. Olshausen himself had seen 34 cases of hæmatocele in 1145 gynecological cases. Seyfert had seen 66 cases

out of 1272. In fact, it was only necessary to look for these cases with intelligence in order to find them. He had expressly stated in his paper that some of the cases were no doubt open to criticism as to diagnosis. In some, this had been drawn from the history and general symptoms, and was not established by local exploration. He would, however, premise that every one had been seen either in consultation or in hospital practice, and that there was a presumption that the symptoms were severe enough to cause anxiety. The facility of diagnosis depended upon the extent of one's experience. Hæmatocele was most liable to be confounded with pelvic peritonitis. He had been familiar with pelvic peritonitis for thirty years. The history and physical signs of pelvic peritonitis from other causes than effusion of blood into the peritoneum differed materially. Dr. Meadows was astonished that eight of his cases attended abortion. The possibility of this occurrence should not be questioned because others had not noticed a similar connection. Again, Dr. Meadows doubted, because so many of Dr. Barnes's cases recovered. It would have been easy to produce a more convincing mortality if he (Dr. Barnes) had punctured the cysts and given purgatives. In reference to the division of the cases, Dr. Meadows failed to see that his design was simply to illustrate the matter from a clinical point of view, not to classify. Lastly came the question of treatment. He considered it most important not to disturb parts recently the seat of severe injury. Rest was necessary to allow the conservative process of encapsulation. Puncture was only necessary when urgent symptoms, as of toxæmia, arose. Dr. Meadows, by dealing with the statistics of Bernutz's cases, had come to a conclusion strictly the opposite of that which Bernutz himself had formed. He (Dr. Barnes) very much preferred the deliberate judgment of Bernutz upon his own cases, arrived at by a process of clinical reasoning and comparison, to Dr. Meadows's statistical deduction.—Dr. SNOW BECK said that his experience led to the conclusion that retro-uterine hæmatocele was comparatively rare. He did not think that rupture of the gravid uterus, or extra-uterine gestation cysts, or ovarian cysts with large effusion of blood into the peritoneum, ought to be included under this term, which was properly restricted to effusions of blood encysted in the pelvic peritoneum, or extravasated into the loose cellular tissue in the pelvis. With these restrictions Dr. Barnes's cases were reduced from 53 to three cases of hæmatocele from rupture of diseased ovaries, and eight cases attending abortion, some of which were of a very doubtful nature. When blood became encysted in the pelvic peritoneum or neighbouring cellular tissue, it was desirable to remove it if possible, and to prevent the cyst from refilling. The danger of allowing it to remain was shown by the cyst sometimes bursting into the peritoneum, or the woman being worn out by constant suffering. However, when it formed an inert mass, causing little inconvenience except from its presence, it would not be desirable to interfere with it.—Dr. MADGE, in reply to Dr. Beck, said that in his case death did not take place from the rupture of the cyst into the peritoneal cavity. There were repeated hæmorrhages from the cyst, the blood passing *per rectum*, and some of the contents of the hæmatocele seemed to undergo changes of an unhealthy character, which induced a pyæmic condition, and the patient died from exhaustion. Dr. Madge said he was the first to bring the subject before the society; his paper was read about ten years ago, and contained a *résumé* of the leading opinions to that date.—Dr. PHILLIPS believed that small effusions of blood into the retro-uterine pouch were of common occurrence. Instances of large effusion extending above the pelvic brim he considered comparatively rare. Excluding those severe cases, where the effused blood resulted from some grave lesion, as the rupture of an extra-uterine fetal cyst, or a gravid uterus, he thought the mortality was not nearly so great as Dr. Meadows implied. There existed but few specimens of retro-uterine hæmatocele in any of the museums. He considered that the peritoneal symptoms described in some monographs on the subject, were exaggerated. They were not necessarily very severe, as pure blood did not set up much peritonitis. He stated that in many cases the retro-uterine pouch descended much lower than represented in diagrams, and that the depth in the pelvis to which the effusion extended, should not be used as an argument against its intraperitoneal seat. He asked for some indications to distinguish between a small inflamed ovarian cyst surrounded by inflammatory adhesions and a blood effusion. The physical signs in many cases afforded but little assistance, and the preceding history might mislead, as urgent symptoms occasionally supervened suddenly from impaction of an ovarian tumour in the pelvis. Generally, however, an ovarian cyst displaced the uterus more to the opposite side of the pelvis, a hæmatocele pushed it forwards. Probably no one would doubt the advisability of emptying the cyst by puncture, if pyæmic symptoms threatened from absorption of putrid contents (which he believed rarely happened if the patient were left alone); but the cases in which tapping was applicable seemed to him to be few. It was certainly not safe to tap before the effusion became encysted;

while at a later period the serous part had in most cases already undergone absorption, and it was almost useless to puncture the remaining mass. He had seen cases, where the blood extended as high as, or above the umbilicus, do perfectly well without surgical interference. Dr. GERVIS said that it appeared to him that some of Dr. Beck's remarks were founded on a misapprehension of Dr. Barnes's views. Dr. Barnes never asserted that certain symptoms referred to by Dr. Beck were the symptoms of peri-uterine hæmatocele, but that, in the cases quoted from his paper, there was pelvic peritonitis, plus more or less intraperitoneal effusion of blood, standing to one another in the relation of cause and effect. Again, Dr. Beck asked, if purulent accumulation be present, what rest would do for the patient; whereas, Dr. Barnes distinctly stated that the indication for puncture was the presence of irritative fever, pointing to the occurrence of local suppuration. On the general question of the comparative frequency of slight effusions of blood into the peritoneum, he (Dr. Gervis) entirely coincided in the opinions expressed by Dr. Barnes and Dr. Phillips.—Dr. GRAILY HEWITT stated that, during the last five years, he had observed in University College Hospital, altogether, he believed, twelve or fifteen cases. They had all recovered, and in no case had puncture been resorted to.—Dr. TILT remarked that, if the German pathologists had found hæmatocele common, the French writers considered it to be very rare. Since he first drew the attention of the British pathologists to hæmatocele in 1853, he (Dr. Tilt) had only met with twelve cases. Pelvi-peritonitis was often mistaken for hæmatocele. The majority of cases required no surgical treatment, but when the collection of blood was considerable and the tension of the sac very great, he had repeatedly punctured it through the vagina, and allowed the blood to drain away of its own accord, thereby greatly relieving the patient's suffering and shortening the duration of the disease.—Dr. GREENHALGH agreed with Dr. Meadows that pelvic hæmatocele was by no means so frequent nor so harmless an affection, as Dr. Barnes would lead the profession to believe. On a rough estimate he (Dr. Greenhalgh) did not think that he had seen more than twenty-five indubitable instances of that affection, notwithstanding he had had extensive opportunities of meeting with such cases. He observed that many of the cases of pelvic hæmatocele which had fallen under his notice, were of a far graver character than those recorded by Dr. Barnes; three cases having died speedily after the attack, and several others requiring much more treatment than the rest-and-do-nothing system advocated by Dr. Barnes. In three cases, puncture and evacuation of the effused blood had been necessitated by the severity of the constitutional symptoms, followed by satisfactory results; and he (Dr. Greenhalgh) had little doubt that, had puncture been had recourse to in some of the other cases, the patients would have made a far more rapid and satisfactory recovery. He inferred that Dr. Meadows attached due importance to rest.—Mr. SPENCER WELLS said that his personal experience of pelvic hæmatocele was chiefly as a sequel of ovariectomy. He believed the less severe forms, where only small quantities of blood were effused and afterwards absorbed, were very common. When the tied or cauterised pedicle was in the pelvis, a good deal of trouble was sometimes observed at each menstrual period for some months, with all the signs of hæmatocele. In the slighter cases, he considered that rest and opiates constituted the best treatment. But there were other cases where a high temperature, rapid pulse, loss of flesh, dry tongue and skin, with a painful distended abdomen, and scanty concentrated urine, showed that the patients were being poisoned by absorption; and here not only puncture but drainage was necessary to save life. Puncture alone might only give temporary relief, or do harm by hastening decomposition of blood or pus; but when a cannula or drainage-tube maintained a free escape for fluid and gas, cases apparently hopeless did well.—The President stated that his experience coincided with those observers who considered slight cases of hæmatocele as of common occurrence.—Dr. MACGOWAN said that he had referred to Dr. Barnes's paper, on the ground that those cases, if unchallenged, might hereafter be used for statistical purposes in a way which their real importance did not warrant. Dr. Meadows agreed with the speakers who had preceded him, as to the comparative rarity of hæmatocele. He entirely concurred in the value of rest in the treatment of these cases; but he thought that the facts which he had brought forward in his paper made it necessary that we should review our practice in this respect—at least in regard to those cases where the quantity of effused blood was more or less considerable. The frequency of spontaneous rupture, either by the vagina or periton, and the escape of the effused blood, seemed to be Nature's method of pointing out the treatment which we ought to adopt. He found, moreover, that the period of convalescence was greatly shortened by the tapping or rupture.

## MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH.

WEDNESDAY, MAY 17TH, 1871.

J. MATTHEWS DUNCAN, M.D., in the Chair.

DR. GILLESPIE showed two Loose Cartilages which he had excised by subcutaneous incision from the knee of a man. Four years previously, Mr. Spence had removed a similar body from his other knee. Antiseptic dressings were used and the case made a good recovery.

Dr. GILLESPIE and Mr. COUGHTREY read a paper on a Case of Extensive Fracture of the Skull and Vertebrae, with extravasation into the cord and ciliospinal region. A lad aged 15 in frolic jumped on to a steam-lift, and in its ascent his head was brought into forcible contact with a beam. He was insensible for a few minutes. There was no scalp-wound, but a fracture of the left parietal bone from the vertex towards the left ear. There was profuse and continued bleeding from the ear. The pupils were equally contracted but sensitive. There was complete paralysis of the lower limbs and all below nipples, with hyperæsthesia of the arms. Paralysis of the bladder was complete. He was quite conscious, but drowsy to the last. Pulse 64, compressible. He died about thirty-six hours after the accident. A detailed account of the *post mortem* appearances was given. The fracture of the skull was extensive and complicated, extending to the meatus auditorius. A thin layer of extravasated blood lay between the dura mater and brain. There was little subarachnoid effusion. The grey substance of the gyri in the neighbourhood of the fracture was contused and ecchymosed. The fourth ventricle showed one or two ecchymosed patches. In the spine the intervertebral disc between the fifth and sixth vertebrae was separated from the fifth, and considerable mobility existed. There existed two extensive extravasations of blood into the sheath of the cord. The bodies of the sixth and seventh cervical and first dorsal vertebrae were extensively fractured. There were extravasations of blood into the grey matter of the cord in the cervico-dorsal region, and also in the dorso-lumbar region. Considerable discussion took place as to the question of the injury of the cilio-spinal region of the cord explaining the contraction of the pupils.—Mr. COUGHTREY thought that probably it did so.—Dr. ARGYLL ROBERTSON was of opinion that the mobility of the pupils disproved this, and probably that the contraction would be better explained by some irritation of the third pair of nerves as a result of the injury to the cerebrum.—Dr. MATTHEWS DUNCAN, Dr. HANDYSIDE, and Dr. JOSEPH BELL also made remarks on various topics brought out in this interesting case.

Dr. MCKENDRICK read a paper entitled Experimental Notes on the Action of Aloin. The experiments were thirty-two in number, and were performed on pigeons, rabbits, cats, dogs, and healthy men. In each case the animal was first weighed, then the weight of ingesta for three days was taken, and also the weight of egesta for the same period, so as to obtain a normal average for comparison; then the drug was administered and its effects noted in the same careful manner. In the pigeons, doses of half a grain and a grain seemed to produce little result. In the rabbits, from three to four grains purged; small doses had no results. On cats the effect of even small doses was very severe, one dying of diarrhoea. In dogs, doses over a grain produced diarrhoea. In men, doses above half a grain induced diarrhoea.—Dr. G. W. BALFOUR and Dr. HAMMOND made remarks on the paper. The latter mentioned that he took the first dose of aloin when it was discovered by the Messrs. Smith twenty years ago, and that on him half a grain acted as a cathartic purgative.

## SURGICAL SOCIETY OF IRELAND.

FRIDAY, MAY 5TH, 1871.

ALBERT J. WALSH, Esq., President, in the Chair.

MR. WILLIAM STOKES communicated two cases illustrative of the difficulties occasionally surrounding the diagnosis of Strangulated Femoral Hernia. A woman, aged 35, was admitted to the Richmond Surgical Hospital on April 22nd, stating that three days previously she had received a kick in the groin. A lump shortly appeared in this situation, and all the symptoms of strangulated hernia set in. There were constipation, tenderness over the abdomen, nausea, and vomiting. On examination, a large globular swelling was noticed in the neighbourhood of the femoral ring. Owing to the urgency of the symptoms, an operation was determined upon. The usual incisions were made over the tumour, when a greatly swollen gland, in a state of high inflammation, was discovered. It was removed, with a rapid amelioration of all the alarming symptoms. The second case was really one of femoral hernia. The patient, a woman of advanced age, was admitted three days before. For sixteen years she had suffered from hernia, the

tumour often returning spontaneously. The day before her admission, however, pain set in in the swelling, which increased in size, and became hard and painful. She could not reduce it. Nausea and green vomiting began, and there was extreme prostration. The abdomen was tense and painful, and the knees were drawn up. When examined, the tumour was of the size of a child's head. It was determined not to operate, but to adopt purgative treatment. Warm baths and purgative enemata were tried for some time without effect. Early next morning, however, a natural motion occurred. The treatment, being so far successful, was persevered in, with the result that two more motions came away, and the vomiting ceased. On May 4th, the tumour was soft and flaccid, though still irreducible, and the patient had lost her anxious look. Next day, the improvement continued. The case was still under observation.—The PRESIDENT briefly detailed the particulars of a case similar to the second one spoken of by Mr. Stokes.—Mr. HARGRAVE recalled an instance in which the late Dr. Geoghegan had operated to relieve most decided symptoms of strangulated femoral hernia, the tumour being situated just outside the ring. On cutting down on the supposed sac, nothing was met with but a gland containing a little fluid. Complete relief and a good recovery followed the operation.—Dr. WHARTON referred to the fact that symptoms of strangulation might be absent when that lesion had actually occurred. He, therefore, believed that those symptoms depended on something not necessarily connected with the lesion in question.—Dr. JAMESON gave the history of a peculiar form of complicated strangulated femoral hernia occurring in an elderly woman. The usual symptoms of strangulation were present. In operating, he cut down on a tumour as large as a walnut when covered with the integuments. An incision was then made a quarter of an inch into the tumour, which proved to be solid, and glandular. No hernial sac was met with. The case ultimately terminated fatally. At the necropsy, it was found that a knuckle of intestine, of the size of a hazel-nut and in a gangrenous state, had become entangled in an enlarged gland. The bowel had escaped injury in the incision, and death was the result of the strangulation alone.—Dr. FREDERICK KIRKPATRICK mentioned a case in which operation failed to discover any hernia; but the patient, a woman, rallied for a time. Obstinate constipation nevertheless continued, and, after six weeks, death occurred. A stricture of the rectum existed ten inches from the anus, and the opening was only as large as a goose-quill.—Dr. BENSON suggested, that in Mr. Stokes's first case a position of parts resembling that described by Dr. Jameson may have been present.—Mr. STOKES considered that the facts narrated went to show that local inflammations in the neighbourhood of the femoral region might give rise to symptoms of strangulated hernia, though that lesion might not itself have occurred.

Dr. ARCHIBALD H. JACOB described a very obstinate case of the Rodent Ulcer, commonly known as Jacob's ulcer. The patient, a lady, had been eleven years under observation by his father and himself. At times, the ulcer extended its ravages, and these exacerbations were invariably preceded by increase of fetor and of discharge. It was also observed that, while the disease was extending in one direction, the affected surface was healing in another. Tentative treatment alone seemed to avail. Hæmorrhages were checked by astringents, and these agents seemed to exercise temporarily salutary influence on the ulcer itself. Those chiefly used were tincture of the perchloride of iron, tannic acid, and on one occasion—nitric acid. Anæmia resulted from the repeated hæmorrhage, and the patient at last sank from asthenia.—Mr. S. HEWITT looked upon the disease, as described by Dr. Jacob, as a form of lupus. Its origin as a tubercle, its situation, the phenomena observed in connection with its simultaneous healing and spreading, and the inefficiency of any line of treatment, were the points on which he based this view.—Mr. HARGRAVE asked whether Dr. Jacob had employed the actual cautery, or had attempted the operation of "sealing" the ulcer.—Dr. WHARTON laid stress on the occurrence of violent hæmorrhages as bearing on the differential diagnosis between this affection and ordinary lupoid.—Mr. STOKES stated, that in similar cases he had attempted excision, but with unsatisfactory results. Among caustics, he had used Landolfi's paste without success, but he had obtained favourable results from the acid nitrate of mercury.—Mr. KELLY would attribute the partial healing to the depletion depending on the occurrence of hæmorrhage.

The PRESIDENT delivered his valedictory address. Having briefly reviewed the work done during the past session, and having given a *résumé* of the various papers read, and of the discussions which they had originated, he congratulated the members on the vitality and usefulness of their Society, and concluded by thanking them for the kindly way in which they had ever treated him during his Presidentship.—A vote of thanks to the President was then carried by acclamation, and the Session was declared closed.

## CORRESPONDENCE.

### AMENDMENT OF THE MEDICAL ACT.

SIR,—In the last number of the JOURNAL, I publicly avowed myself the sole author of the letter to the editor of the *Lancet* signed by the General Secretary, and published on April 1st. Dr. Paget, on the part of himself and his colleagues, took exception to the last paragraph in that letter, which was as follows: "The statement" (one amongst others made in the previous leader of the *Lancet*) "that the Reform Committee 'derived their only claim to collective consideration from the presence of the five eminent men who seceded from them,' is also incorrect, inasmuch as they were never on it. They were all members of the General Medical Council, and retired from the executive of the Association because they were opposed to the direct representation of the profession and to the consequent diminution of the influence of the Universities and the Corporations in the General Medical Council, which it is your object to effect."

Dr. Paget complained that this paragraph misrepresented the reasons and motives of the resignation of himself and his colleagues, which were not "that they were opposed to the direct representation of the profession," but that those who acted in the name of the Association were unwilling to accept from a friendly Government any measure of medical reform which did not contain the special provision for direct representation.

The letter to the *Times* announcing their resignation is as follows.

"Sir,—With reference to a recent report in your columns, we beg to state that, in the late meeting of the British Medical Association, held at Newcastle-upon-Tyne, we found ourselves compelled to resign our seats on the Council of that body. As members of the General Council of Medical Education and Registration, we had advocated the main provisions of the Amended Medical Bill introduced into the House of Lords by the Lord President of the Privy Council—provisions which, in our judgment, were of the utmost importance to the public weal. The Bill, it is believed, was withdrawn in the House of Commons by Mr. Forster in consequence of the course pursued by the Direct Representation Committee of the Association. That course was subsequently approved by a vote of the Association at Newcastle. We, therefore, could not, in justice to ourselves or the members of the Association, continue any longer to belong to its executive. The question of the permanent construction of a Medical Council of Education is one of grave importance. It is intimately connected with other questions and interests entirely extra-professional, and it cannot, therefore, be properly dealt with by any hasty or one-sided legislation.

"We are sir, your obedient servants,

"GEORGE PAGET, Cambridge.

WILLIAM STOKES, Dublin.

HENRY W. ACLAND, Oxford.

H. WYLDRORE RUMSEY, Cheltenham.

DENIS EMBLETON, Newcastle-upon-Tyne.

"August 29."

In reply to Dr. Paget, I wrote him a letter, which he published in the *Lancet* of May 27th. The statement in the first paragraph of that letter, "because the Association by its vote at the Newcastle meeting approved of the conduct of the Direct Representation Committee of the Association in not accepting the Medical Acts Amendment Bill of last session," was drawn from the letter to the *Times*. I also accepted Dr. Paget's statement of the reasons of the resignation of himself and his colleagues, though I objected to the imputation of any disregard of professional and public good on the part of the Committee. It is with the deepest regret I have found that this letter was not deemed satisfactory; and that, in consequence, Dr. Paget and his colleagues, concluding that the whole Reform Committee were implicated in the correspondence, have resigned their connexion with the Association.

It is, I believe, no unusual course for the chairman of a committee to take independent action when circumstances render it necessary. The letter to the *Lancet*, *terribila causa belli*, was written in reply to a leader, and was intended for insertion in the following number. There was, therefore, no time to consult the members of the Reform Committee. The letter appeared with the signature of the General Secretary; but the resignation of Dr. Paget and his colleagues determined me to proclaim myself without any delay the sole author.

In order to give full expression to the views of Dr. Paget and his colleagues, I must beg the insertion of the letter in which they resigned at Newcastle their seats on the executive, and in which they seem to me to deprecate the interference of the Association in medico-legal questions. I never saw this letter until the meeting of Council held at

Birmingham on June 6th instant, when Dr. Paget and his colleagues had already resigned their connexion, as members, with the Association.

I can only hope that an involuntary error on my part, for which I have desired to make every reparation, may not be permanently visited on the Association. The error in no way added to the force of the letter complained of. I am, etc., EDWARD WATERS.

Chester, June 28th, 1871.

The following is a copy of the letter written at Newcastle by Dr. Paget and his colleagues.

"I, Eldon Square, Newcastle-on-Tyne, August 11th, 1870.

SIR,—We, the undersigned, beg leave to resign our places on the Council of the British Medical Association. We take this step with sincere regret, but feel compelled to take it. We are, and have been, anxious to promote in every way in our power such education and such legislation as may in our judgment maintain and increase the just esteem in which every branch of the profession of medicine is held in this kingdom. We believe that the thwarting the sincere attempts of a friendly Government in this direction to be injurious to this object. Having been engaged, in the discharge of a duty imposed on us under the Act of Parliament of 1858, in repeated consideration of the Medical Bill now withdrawn in consequence of the refusal of the Committee of the Association to accept what appears to us a fair offer of the Government (a Committee of the House of Commons on the question of direct representation), we feel that we cannot now consistently share any responsibility in the Council of the Association. We do not at present withdraw from the Association, because, much as we deplore the introduction at these meetings of medico-political questions, we hope to be able from time to time to join in what we consider the great objects of the Association—the friendly discussion in different parts of the kingdom, at general meetings and in sections, of all questions bearing directly on the improvement of medical science.

"We are, sir, your faithful servants, GEORGE EDWD. PAGET, H. W. ACLAND, WM. STOKES, D. EMBLETON, H. W. RUMSEY.

"The President, British Medical Association."

#### DEATHS FROM CHLOROFORM.

SIR,—Among your "leaders" of June 24th, you have an article on the above subject, wherein you criticise with great justice Professor Lister's conclusions as to the mode of death in anaesthesia induced by chloroform, and his only method of treatment.

Without attempting to explain the various causes of death, in different individuals and under every variety of circumstance, whilst under the action of chloroform, I shall content myself with daring to "contravene" the Professor's statements.

It will generally be allowed that the immediate and common cause of death during the induction of anaesthesia by chloroform or any other volatile anaesthetic ingested by the organs of respiration is, primarily, paralysis of the heart, and secondarily, paralysis of the respiration; but the paralysis of the respiration follows so closely upon that of the heart that, in practice, it is found to be impossible to say which is first, nor is it, in my opinion, of vital importance which is first; suffice it that it is well to know that death, in the vast majority of cases, begins at the heart. It will also generally be admitted that, in the majority of instances where death has actually supervened, a certain and considerable percentage of chloroform is and must be within the area of the circulation, paralysing the great nerve-centres; and that this anaesthetic and paralysing agent entered the circulation by the lungs, and, so far as we know at present, it also makes its exit *en masse* by the same channel.

If these premises be true, then it follows that the majority of those who die from chloroform, die from pulmonary asphyxia from stoppage of the action of the heart, induced by a poison in the blood, which exerts an anaesthetic and paralysing influence upon the entire nervous system, and through it upon the whole substance of the body.

In the face of this, Professor Lister has the hardihood to tell us that "firm traction upon the tongue with artery-forceps at once clears away the barrier." With all deference to a professor of surgery, this is the most ridiculous and vain way of getting rid of a poison circulating in the blood and paralysing the great nerve-centres, that any one could well conceive; but the most remarkable part of Professor Lister's theory and practice is, that the firm traction on the tongue does not act mechanically, as most of us believe; it does not operate by preventing the paralysed tongue from falling back and closing the glottis to the entrance and egress of air; but he holds that it acts simply as a stimulant to the nervous system, "like a dash of cold water on the face or chest." The brilliancy of the comparison is perfection, and it reminds one of his student on hospital cases, when, in the sublimity of our ignorance and the sportiveness of youth, some are charmed with the very idea of a case of opium-poisoning, where flagellation

with a wet towel and such like barbarous and more than useless practices were, and perhaps still are, thought to be the treatment *secundum artem*.

Really, after twenty-four years' experience of chloroform, we ought to know our work better than to treat poisoning under its influence as we would an ordinary faint. Fresh air, the recumbent position, smelling salts, strong liquid ammonia, etc., rubbed over the face and nostrils, raising the head and shoulders, and pouring wine down the throat, and last, though not least, stimulating the nervous system by laying violent hold of the tongue with artery-forceps, and using firm traction on the same, are all very well, but they are not the primary much less the only means, which ought to be relied upon in a case of chloroform-poisoning. Professor Lister entirely forgets that the nervous system of the patient is not paralysed from want of a stimulant, but on account of the presence of a poison, which is acting upon the pulmonary nerves in especial, and on the great nerve-centres in particular. This being the case, it is perfectly useless to stimulate nerves which refuse to be stimulated. We might as well try to stimulate a dead body, or talk a drunk man sober, or attempt to rouse him into sobriety, or to "clear away the barrier" to his healthy respiration, by firm traction applied to his gustatory nerves by arterial or any other form of forceps. The late Sir James Simpson was the first to point out the necessity of drawing forward the tongue in chloroform poisoning. He was in the custom of using his finger, sometimes the uterine sound; and I have once seen him use a vulsellum, because it was at hand. He looked upon the practice as simply mechanical, and not vital. In my own opinion, there is no instrument for the purpose that is equal to, or can surpass, the forefinger, or the fore and middle fingers of the left hand, or, in an ambidexter person, of either hand.

If a patient be so little under the anaesthetic influence of chloroform as to be capable of being roused to sensibility by the grip of a pair of artery-forceps on the tongue, he is certainly not deep enough under chloroform for almost the most ordinary surgical operation requiring its protecting and benign influence; but what is much more likely, the patient most probably has been in a common faint, from which he would have recovered if simply left alone. Professor Lister surely does not require to be reminded that the patient who is in a condition of deep anaesthesia—the depth requisite for amputation of the thigh, for instance—is, for the time being, as dead to all sensation and sensibility as a corpse; and until a certain amount of the poison is eliminated or has expended itself, so long must the patient remain incapable of being roused. Such being the case, our first duty is to administer an emetic by the lungs, or, by means of an air-pump, empty the lungs and blood of the vapour of chloroform which they contain. In other words, induce artificial respiration, not by the Marshall Hall or Silvester methods, but by such method or methods as the operator finds to be the most convenient and the most successful. The method which I myself prefer I must leave to another occasion.

If a poison such as alcohol, opium, or the like, has entered the system by the stomach in a quantity dangerous to life, we have recourse, primarily, to the stomach-pump and emetics, secondarily, to antidotes, and thirdly, to stimulants. If another, but a similar and more powerful narcotic poison, has entered by the lungs and also makes its exit by these organs, what can be more rational than to follow the same order—namely, to assist Nature in expelling the poison from the lungs and blood, by keeping up artificially what she is prevented fulfilling by virtue of the poison she has inhaled; secondly, by using antidotes—fresh air being the best known; and third and lastly (*not firstly*), by the use of stimulants. After the first two have been properly executed, it will be time enough and not too late to stimulate the nervous system with artery-forceps or any other surgical or other means of rousing the vital powers. The *modus mendendi* by the respiratory system is so new to us, we have not had time to realise our new position, or the difficulties of the situation. We have two "new tracks" to explore—the pulmonary and the areolar—and before long, if we have not had some of it already, we shall have the serous also to consider.

One word as to deaths from chloroform being preventable accidents. To some extent, I believe, they are so; but I do not and I can never believe, with Professor Lister, that they are altogether the result of carelessness and the omission of the simple precaution of forcible and firm traction of the tongue. Let him who thinketh he standeth, take heed lest he fall. The late Sir James Simpson was a man than whom no one ever had an equal confidence in himself and in chloroform—than whom no man ever had, or is likely to have, an equal, leave alone a greater experience of chloroform—and than whom no man could be more keenly jealous of anything going wrong with his darling offspring chloroform, in his own or in the hands of another; nevertheless, during the last year of his marvellously successful life, he was fated to lose one patient whilst under the influence of chloroform administered by his own

hands. Did the patient die for want of traction—firm traction on the tongue? Any one who has had the honour of Sir James's professional acquaintance, must know that, if a patient died under the influence of chloroform administered by himself, it was no fault of Sir James Simpson's, nor was it owing to any carelessness or neglect of the minutest measure necessary or likely to be of any use to assist in the resuscitation. There is a limit to all human power, and if we have honestly exerted our utmost to save life, we are in no way to blame—we can do no more. A death from chloroform is quite possible to occur even in the hands of Professor Lister, and all the more likely if he persists in placing his chief, if not entire, reliance in *firm traction on the tongue with artery-forceps*, a step of "unspeakable importance."

In conclusion, although accidents will and do occur, it is no reason why we should not strive our very utmost to lessen their number. In a future communication I may enter upon this point, and impart more of my experience on this deeply important and interesting subject.

I am, etc., THO. SKINNER, M.D.

Dunedin House, Liverpool, June 28th, 1871.

## MEDICAL NEWS.

### PAPERS FOR THE ANNUAL MEETING AT PLYMOUTH, 1871.

THE following are the names of the Honorary Secretaries of Sections for the approaching Annual Meeting.

*Medicine*.—Dr. Clay, Plymouth; Dr. Wade, Birmingham.

*Surgery*.—W. P. Swain, Esq., Devonport; C. Steele, Esq., Clifton, Bristol.

*Midwifery*.—Dr. J. Rolston, Stoke, Devonport; Dr. Phillips, 26, Finsbury Square, London.

*Public Medicine*.—Dr. Row, Devonport; David Davies, Esq., Queen Square, Bristol.

Gentlemen proposing to read papers or to forward communications for the Annual Meeting are requested to communicate with the least possible delay with the Sectional Secretaries, in order that the titles of their papers may be duly announced, and that arrangements may be made for the order in which they are to be read. Abstracts should at the same time be prepared, and communicated beforehand to the JOURNAL, in order that copies of such abstracts may be issued by us for the simultaneous use of the other medical papers.

### COLLEGIATE ELECTION.

THE annual meeting for the election of Fellows into the Council of the Royal College of Surgeons took place on Thursday the 6th instant. The hour for commencing the proceedings was 2 o'clock, but long before that time many Fellows attended to examine the interesting collection of preparations about to be added to the Museum, which, owing to the great zeal of the Conservator, Professor Flower, increases in number and interest every year. An abstract of his able report appears in another page of the BRITISH MEDICAL JOURNAL.

Punctual to the time appointed, the President, Sir William Ferguson, accompanied by the Vice-Presidents, Messrs. Busk and Hancock, entered the Library, and, having shortly explained the objects of the meeting, added that three of the four retiring members of the Council offered themselves for re-election, viz., Messrs. Edward Cock, George Busk, and F. Le Gros Clark (Mr. S. A. Lane having declined being nominated); the other candidates, taking them in chronological order, were Messrs. T. Spencer Wells, George Critchett, and Barnard W. Holt. The voting then commenced, and was concluded at 5 o'clock, when Mr. Stone commenced recording the votes as they were announced by Mr. Trimmer, previously to which the President invited any Fellows, so inclined, to act as scrutineers. At the conclusion of this duty, the numbers having been declared correct, the President announced that the successful candidates were Messrs. Busk, Clark, Wells, and Critchett. The numbers polled by each candidate were as follows, viz. :—

Mr. Wells.....	131.....	including 4 plumpers.
Mr. Critchett .....	130.....	" 7 "
Mr. Clark.....	127.....	" 9 "
Mr. Busk .....	117.....	" 1 "
Mr. Holt .....	104.....	" 7 "
Mr. Cock .....	74.....	" 10 "

It appears that 228 Fellows recorded their votes;\* and, as showing

\* The facilities for voting were greatly increased on this occasion by adopting the plan of the School Board election, in having several compartments, where the voting-papers could be filled up with the secrecy necessary sometimes, and which was duly appreciated.

the continued interest taken in these elections, it may be mentioned that Fellows attended from distant provincial towns, as Messrs. Wiblin and Osborn, Southampton; Green, Bristol; Carden, Worcester; Fox, Broughton, Winchester; Southam, Manchester; Campbell, Stourbridge; Dalrymple, M.P., Norwich; Wood, Shrewsbury; Humphry, Cambridge; Smith, Stevenage; May, Reading; Holman, Hunstpierpoint; Allard, Tewkesbury; Brown and Bell, Rochester.

In the evening a very large number sat down to dinner at the Albion Tavern, under the chairmanship of Mr. H. D. Carden of Worcester, who was supported by many distinguished visitors; and, thanks to the indefatigable exertions of Mr. T. Carr Jackson, the Honorary Secretary, every Fellow appeared thoroughly to enjoy the agreeable reunion.

UNIVERSITY OF DUBLIN.—At the recent examination for the Degree of Bachelor in Medicine, held in Trinity Term, the following candidates passed in the order of merit indicated.

1. Jacob O'Connor; 2. John G. Rogers; 3. David Kennedy; 4. Thomas Drapes, Patrick Molony; 6. Thomas B. Worthington, William M. Whittaker, Richard Quill; 7. Henry J. Tweedy; 10. Maurice Blunden; 11. Thomas Hamilton Moorhead; 12. James Armstrong; 13. Henry Comyn; 14. Andrew F. Dobson; 15. Richard D. White, George Gibson, Thomas J. Browne; 18. Christopher Elliott; 19. Otway P. Browne; 20. John Waugh.

The following gentlemen have passed the examination for the Degree of Master in Surgery.

1. Patrick J. Molony; 2. John G. Rogers; 3. James Armstrong; 4. Richard Henry Quill; 5. Thomas B. Worthington; 6. Edward M. Courtenay; 7. Francis G. Mayberry; 8. John Waugh; 9. Otway Peter Browne; 10. Henry Edward Comyn.

*Previous Examination in Medicine*.—The following have passed in all the subjects.

- Andrew Clarke, George A. Pearce, Charles A. Cooper, Thomas F. Fleetwood, Phineas B. Tuthill, John P. McNeill, George A. Bluett.

### MEDICAL VACANCIES.

THE following vacancies are announced :—

BLACKBURN and EAST LANCASHIRE INFIRMARY—House-Surgeon.  
BRIDGNORTH UNION, Salop—Medical Officers for the Workhouse and Districts 3 and 4.  
BRISTOL GENERAL HOSPITAL—Surgeon.  
BURY, LANCASHIRE, DISPENSARY—Resident Medical Officer.  
DERBYSHIRE GENERAL INFIRMARY, Derby—Resident Assistant House-Surgeon; Two Dental Surgeons; Non-Resident Dispenser.  
DEWSBURY UNION, Yorkshire—Medical Officer for the Mirfield District.  
GATESHEAD DISPENSARY—Resident Medical Officer.  
GENERAL HOSPITAL and DISPENSARY for SICK CHILDREN, Bridge Street, Manchester—Resident Medical Officer.  
GREAT YARMOUTH, Norfolk (Parish of)—Medical Officer for the North District.  
GUISBOROUGH UNION, Yorkshire—Medical Officer for the Danby District.  
HOSPITAL FOR SICK CHILDREN, Great Ormond Street—Assistant-Physician.  
HUDDERSFIELD and UPPER AGRIGG INFIRMARY—Physician.  
HUNSLT UNION, Yorkshire—Medical Officer for the Templenewsam District.  
INFIRMARY FOR CONSUMPTION and DISEASES OF THE CHEST, Margaret Street, Cavendish Square—Visiting Physician.  
INFIRMARY for EPILEPSY and PARALYSIS, Charles Street, Portman Square—Physician.  
LEEDS GENERAL INFIRMARY—Assistant Resident Medical Officer.  
LEEDS PUBLIC DISPENSARY—Junior Resident Medical Officer.  
LIVERPOOL ROYAL INFIRMARY—Physician.  
LOUDOUN, Ayrshire—Parochial Medical Officer and Public Vaccinator.  
METROPOLITAN FREE HOSPITAL, Devonshire Square—Assistant-Physician.  
MIDDLESEX HOSPITAL—Physician; Assistant-Surgeon.  
MIDDLESEX HOSPITAL MEDICAL COLLEGE—Lecturer on Physiology, including Practical Physiology.  
NAAS UNION, co. Kildare—Medical Officer and Public Vaccinator for the Clane and Timahoe North Dispensary District.  
PLYMOUTH PUBLIC DISPENSARY—Dispenser.  
PLYMOUTH UNION, co. Dublin—Medical Officer for First Division of the Kingstown Dispensary District.  
ROYAL ORTHOPEDIC HOSPITAL—Resident House-Surgeon & Apothecary.  
QUEEN'S COLLEGE, Birmingham—Joint Professor of Anatomy.  
ST. MARTIN'S-IN-THE-FIELDS—Medical Officer of Health.  
ST. PETER'S HOSPITAL FOR STONE, etc., Berners Street—House-Surgeon.  
ST. THOMAS'S HOSPITAL—Resident Assistant-Physician; Assistant-Surgeon.  
SUFFOLK GENERAL HOSPITAL, Bury St. Edmunds—Physician.  
WEST LONDON HOSPITAL—Junior Physician.  
WESTMINSTER HOSPITAL—Assistant Surgeon.  
WIRRAL UNION, Cheshire—Medical Officer and Public Vaccinator for the Upton District.

[For Poor-law Vacancies see Poor-law Department.]

DR. F. D. LENTE has been appointed Professor of the Diseases of Women and Children in the University of New York.

SUSSEX and BRIGHTON MEDICO-CHIRURGICAL SOCIETY.—Mr. Jardine Murray was elected President, and Mr. George Tatham, J.P., Vice-President, of the Sussex and Brighton Medico-Chirurgical Society, at the annual general meeting on Tuesday, 2nd July, 1871.

## THE HASTINGS PRIZE ESSAY,

1870.

ON DIGITALIS: ITS MODE OF ACTION  
AND ITS USE.\*

By J. MILNER FOTHERGILL, M.D.,

Late Senior Resident Medical Officer to the Public Dispensary, Leeds.

WE will now proceed to the consideration of each proposition in detail.

1. *Increased Arterial Distension and Tension.*—The immediate effect of increased contraction of the ventricle and more complete emptying of the chamber is, that a greater volume of blood is thrown into the aorta, and a more perfect arterial tension produced. Thus we have improvement in the whole circulation, and relief of the systemic symptoms. Cyanosis or blood-stasis is relieved by the more perfect delivery of blood, by increasing the *vis a tergo*; while the emptying of the distended veins assists in inducing a more perfect general circulation. The pulmonic circulation shares in this improvement, and thus the congestion is abated, and with it the dyspnoea. For, when there is so much extra bulk of blood within a given thoracic space, there must be less room for the reception of air on inspiration. When there is an accumulation of carbonic acid in the blood, the improved circulation brings it more rapidly into contact with the pulmonary membrane, and a more perfect interchange of carbonic acid and oxygen takes place, the blood is more thoroughly purified, and the condition of carbonic acid poisoning—the result of wear within the organism—is relieved; thus one of the most dangerous sequelæ is, for a time at least, held at bay. Relief of other consequences, as dropsy, etc., follows for the same reason. The relief thus obtained is the direct result of a larger volume of blood being thrown into the aorta; for after that the arterial recoil completes the propelling impulse. As long as the arterial coats are sound and retain their elasticity, the ventricular contraction merely produces arterial tension; the arterial recoil is the propelling power after that. When the arteries are rendered less elastic by atheroma, or endarteritis deformans, hypertrophy of the ventricle follows, and the blood is propelled by a sustained effort, very evident in a good sphygmographic tracing, and evident in the pulse at the wrist. Ordinarily, however, the arterial elasticity and recoil complete the impulse received from the ventricular contraction. The greater, then, the distension, the greater the arterial recoil. We thus come to—

2. *Increased Arterial Recoil.*—The arterial recoil, besides completing the impulse received from the ventricular contraction, has an action which is rarely sufficiently recognised. The propelling power through the coronary circulation is the arterial systole. Contrary to other arteries, the propelling power into the coronary arteries is solely the arterial recoil or systole; opening out from the sinuses of Valsalva, they run in a direction opposite to the current occasioned by the ventricular contraction. But the arterial recoil, arrested in the backward direction by the semilunar valves, fills the coronary arteries, and that, too, during the diastole, or heart's period of rest. The question of arterial tension and recoil thus bears directly on the circulation through the coronary arteries—the nutrient arteries of the heart. Thus, too, the blood-supply is secured to the muscular walls of the heart during their period of rest, and not during their activity, which would oppose an obstruction to the circulation, and which would be the case if the ventricular systole were the propelling power through the coronaries. It is thus easy to see how the blood-supply of the heart itself is more perfect, from its being associated with the arterial, rather than the ventricular, systole. Thus increased arterial recoil leads directly to—

3. *Increased or Improved Coronary Circulation.*—It being thus seen how the coronary circulation takes its rise in the arterial recoil, it is easy to see how an improvement in the arterial distension leads to a more perfect circulation through the coronary arteries, and thus to a more perfect supply of blood to the heart's structure, and a freer supply of nutrition to it. The condition of the muscular structures is intimately associated with their blood-supply. Whenever the blood-supply is defective, the muscles deteriorate, and their efficiency is interfered with. However rich the blood may be, and supplied with nutritive material by perfect digestion, if the circulation through any part be interfered with, that part suffers, and does not benefit by the abundance

of nutritive material in the blood. If the blood be impoverished, then, of course, the nutrition of every part is interfered with, but still more so in the part also labouring under obstructed local flow. The arterial recoil has much to do with the general circulation, no doubt, and the unsustained pulse of unfilled—that is, undistended—arteries is well known; the sphygmograph shows a rapid fall after the rise of the systole. This unfilled condition affects all parts; but the heart-structure, through which the coronaries run, is most affected. Their impulse being solely that of arterial recoil, the want of it is a serious drawback to the coronary circulation; while, at the same time, the incessant action of the heart demands a very perfect nutrition to preserve its integrity. Thus, then, improved action of the ventricle leads to increased arterial tension, and through that, by its increasing recoil and improved coronary circulation, to more perfect self-nutrition. Thus hypertrophy tends to perpetuate itself, though to an inferior extent, where there is aortic regurgitation or atheroma; that is, loss of arterial elasticity. In these conditions the recoil no longer fills the coronaries, and a deficient flow sooner or later impairs the structural integrity of the heart. When, however, the dilated or distended heart, accompanied by a rapid, feeble pulse, evidencing a diminished arterial tension, is just pumping a little off the top of the contained blood, there is an inherent probability of tissue-degeneration following at no distant date. The feeble impulse and lessened recoil do not fill the coronary arteries; while the rapidity of the contractions, by infringing on the heart's period of rest between the beats, does not afford the pause during which the coronary arteries supply the heart-walls with nutrition. Thus we see how the improved ventricular contraction leads directly to a better tissue-nutrition; that is, to a consequent hypertrophy. Thus a more perfect action of the ventricle leads to a more perfect nutrition of itself by a special provision, as well as by the general law of increased action leading to increased nutrition, which holds good in all parts of the body equally.

4. *Increased Nutrition of the Heart.*—The improvement in the circulation by supplying more nutritive material to the muscular structure of the heart, and, at the same time, a more perfect removal of waste material, furnishes one factor in the question; the increased systole and lengthened diastole furnish a prolonged period of rest—another factor; and the increased muscular activity, a greater demand for nutrition. There are thus aggregated all the circumstances favourable to improved nutrition.

5. *Compensating Hypertrophy.*—This increased nutrition leads in a direct manner to hypertrophy. The well known instances of the arm of the blacksmith and the leg of a ballet-dancer demonstrate the growth which accompanies activity with a good supply of nutritive material. For, without the nutrition, the activity leads to degeneration, as seen in the muscles of the top-sawyer mentioned in Chambers's *Clinical Lectures*. But, with the improved circulation, all parts are improved; there is better appetite, and more perfect digestion. The relief of the systemic symptoms has set every organ into more perfect action. A more perfect elaboration furnishes more nutrition to the blood, now more rapidly circulated through every organ. From a widening circle of troubles, there is now a widening circle of improvement felt everywhere. The muscular activity, causing a greater demand for formative material, finds it provided by the very action that now calls for it, and tissue-activity leads directly to improved tissue-growth. It matters little whether this be by reduplication of fibres, or increase in length and strength; sufficient that it exists. Thus the muscular walls are better enabled either to resist the distending action of the blood forced in under greater pressure, or to overcome an obstruction to the flow of blood forward. Hypertrophy of muscular tissue is the restoration of the balance, as the result of natural processes. Compensatory hypertrophy frequently enables serious lesion to be borne without any great constitutional embarrassment. It is the way in which the system again strikes the balance in well-nourished individuals; and, as a natural process, it is only too desirable to imitate it and favour it. Compensatory hypertrophy, again, restores a balance between the opposing forces of propulsion and obstruction. When hypertrophy is sufficiently pronounced, an almost perfect compensation may be said to exist. Niemeyer states that a huntsman in Griefswald, who suffered from "extensive stenosis and aortic insufficiency, and immense excentric hypertrophy of the left ventricle, performed all the manœuvres and forced marches of the army without difficulty" (vol. i, fol. 347). Compensatory hypertrophy is Nature's mode of repairing injuries to the heart's integrity; and in treatment I have striven to make it mine, and certainly not without success. By a proper recognition of this principle, and of the means by which it may be attained, a much more effective treatment of heart-lesions may be resorted to than is currently believed. *Experto crede.*

6. *Considerations on Atheroma and Fatty Degeneration.*—The question of atheroma, however, materially interferes with these changes at

\* Continued from page 29 of last number.

every step. It may be desirable, and not uninstrucive, to follow for a while this interference. Atheroma is essentially a parenchymatous inflammation of the inner arterial tissues, and may either exist in patches or be more general, leading to dilatation of the arteries, and loss of elasticity. When the arterial elasticity is impaired, the artery distended by the ventricular systole is unable to recover itself. It thus remains more and more distended, and when possible, elongated—*i.e.*, tortuous. This impaired elasticity then lessens the recoil; the distension and elongation of the arteries interfere with the recoil, and instead of perfect recoil, the artery remains permanently enlarged. This change goes on gradually, incessantly aggravated by exertion and all calls on the heart for increased action. The arteries become elongated and distended, from the aorta to the tortuous temporal artery; they are increased in length and breadth; they become, too, more brittle and more easily ruptured by strain. Here, now, we see a wonderful instance of conservative change, tending directly to prolong the existence of the organism. The diseased arteries recoil less perfectly, and thus the coronary circulation becomes involved and its circulation diminished, and thus impaired nutrition of the heart; and from that, again, lessened and impaired activity, and thus diminished risk of the heart rupturing the diseased and friable arteries. Thus we see that not only is fatty degeneration a preservative lesion, as Sir William Jenner showed at Leeds, but that that very change which is preservative in its action, is entailed by the diseased condition of the arteries, which the very want of that lesion would endanger. Thus the changes go on, hand in hand; the more diseased, brittle, and non-elastic the arteries, the less their power of recoil, and thus impaired structural integrity of the heart and impaired contractile power. The diseased arteries thus fortunately lead to the very muscular change imperatively necessary in order to prevent the heart from rupturing them. Where the atheroma is general, there is a stronger probability of fatty degeneration following, and thus this condition is more favourable to life than when the atheroma is in patches. Where the atheroma is deposited in ring-like, annular patches, encircling the aorta at the branching off of some smaller artery—its favourite seat—it is more fraught with danger. The hypertrophy consequent on the obstruction to the flow, and increased tension resulting from the obstruction, does not so soon undergo preservative degeneration, as the sound parts preserve their elasticity and recoil fairly. Thus the obstruction of the isolated masses, especially if annular, keeps up the hypertrophy by increasing the tension behind them and the results of increased arterial tension, and thus endangers the patient's existence by the increased risk of some degenerate mass giving way. In these conditions, increased ventricular action could only render them more and more dangerous; the greater contraction and distension would try still farther the degenerate vessels, and could only slightly improve the coronary circulation, and thus only to a small extent diminish the risk of arrest of the heart's action, while it would certainly greatly enhance the more imminent risk of arterial rupture. If ever hypertrophy is to be regarded as otherwise than an unalloyed good, it is in these conditions. Certainly any attempt to secure it artificially in the manner described, would be detrimental to the patient's real interests; as the attempt to extenuate one danger would greatly enhance the hazard of another.

*Use in Hypertrophy.*—In hypertrophy of the heart, perhaps, the action of digitalis was first, and is perhaps most readily, observed. For, hypertrophy being essentially compensatory, balance between the blood to be driven and the power to drive it is being already re-established by the efforts of nature. Of course, the effect of a drug whose action is to drive the ventricle into contraction, would be most quickly and evidently apparent in this condition, where a restoration of the balance is being wrought out, than in dilatation where no such compensatory change is being attempted. In hypertrophy, no great amount of the drug would disturb the balance in the opposite direction, and then the symptoms of digitalis poisoning—*i.e.*, of the drug driving the ventricle into an abnormal state of contraction—would be readily produced. This condition was thought to be due to the drug producing a marked sedative effect on the heart, and was considered the strongest proof of its sedative action. The condition of collapse is due to a defective arterial distension, and if that is brought about by a small bulk of blood being thrown into the aorta at each ventricular systole, it matters not whether it be due to a distended ventricle just pouring a little off the top of the contained blood (as was thought the case), or to its being in a state of unusual constriction, and only admitting partial distension on the auricular contraction. Of course, in dilatation much larger doses are not only tolerated, but required; and from there being no attempt at compensating hypertrophy to restore the disturbed balance, a greater stimulus to contraction is necessary to produce the desired result. It is thus comparatively easy to understand here how the early discoverers, who perceived such marked results follow the use of small doses

of digitalis in hypertrophy, conceived the idea of its being a sedative, and dreaded its use in dilatation; in fact, regarding the use of large doses in dilatation as open heresy. A knowledge of its real action, however, explains in a satisfactory manner the apparent anomaly, and explains its effects in each condition; its almost magical effect in hypertrophy in small doses; its tolerance in large doses in dilatation. Thus we see how digitalis is tolerated in large doses for months—nay, years—in cases of confirmed dilatation, where its action, or that of some substance of similar property, is necessary to the preservation of the organism. In dilatation, where the system is confessedly unequal to the establishment of compensatory muscular hypertrophy—of a balance again being struck between the forces of obstruction and the power to overcome it—the use of a drug whose action is to throw the ventricle into a state of tonic contraction is readily understood as being of the greatest service; and this also explains how its use in large and continued doses is not only not productive of symptoms of poisoning—*i.e.*, of ventricular spasm, which was once imagined to be due to an accumulation of the drug in the system in some mysterious inexplicable manner—but is even necessary to the continuance of life. Without it, or some similarly acting drug, dilatation must become only more and more extensive, and hand in hand with that extension must be an increasing inability on the part of the heart to recover itself; hence still more enfeebled circulation, blood-stasis and its consequences, until the widening vicious circle ends in somatic death. In hypertrophy, where the system is equal to an attempt at restoring the disturbed balance by increasing the muscular driving power, and where occasional palpitation alone reveals the remaining inequality, the use of digitalis soon enables the sympathetic ganglia and other muscular servants to get over the difficulty, and tides on the system, until a more perfect histogenesis has again struck a balance, and a permanent equilibrium is established. In this condition of compensatory growth and power, the continuance of the drug would soon be fraught with a new danger from the ventricular contraction becoming excessive. This, I believe, is the true explanation of an apparently opposite action of digitalis, which has long divided the ranks of medicine. It is not that hypertrophy is any bar to its administration, only it is required in less doses. As long as a heart is equal to its work, neither patient nor physician would interfere; but when its inability is revealed by palpitation and the other evidences of over-taxation, hypertrophy does not forbid the use of digitalis, but it is only required in small quantities, as by these small quantities the desired results can be obtained. But it must not be given on any idea of its tranquillising action being in its nature allied to that of a narcotic or a sedative; it is by enabling the heart to contract without laboured effort that it calms excitement. Niemeyer states: "Digitalis in pure uncomplicated hypertrophy is unsuitable. As has been brilliantly demonstrated by Reich, the results of experiments with this medicine on dogs stand in glaring contradiction to the conclusions drawn from experience at the bedside. (On the Employment of Digitalis in Disease of the Heart. Inaugural address under Professor Niemeyer, Tübingen, 1864.) The action of digitalis, under the use of which innumerable cases of disease of the heart, cyanosis, dropsy, hepatic engorgement, and suppression of urine have been made to subside, is not to lower the centrifugal pressure of the arteries, but rather to increase it. Its use is indicated in diseases in which the action of the heart is weakened, but never in cases where it is augmented" (vol. i, fol. 315) *Text-Book of Practical Medicine*.

*In Valvular Disease.*—In valvular disease, no effect must be expected from digitalis, except so far as it acts on the muscular walls. It happens, however, that alteration in the muscular walls is compensatory; in injured valves so much so, that life may be maintained for years, and sometimes with a fair share of activity, in the presence of serious valvular mischief. Dr. Chambers (*Clinical Lectures*) states: "The existence or non-existence of valvular disease lies not so much in the injury it inflicts itself, as in the likelihood of the induction of other lesions of the heart. If the muscular structure remain healthy, injured valves do not appear capable of causing death." In obstructive disease this is readily comprehended, for it can be reduced to simply this. It is necessary for the wants of the system that so much blood be driven through a certain orifice in a given time; and if that orifice be narrowed or otherwise partially occluded, for this to be accomplished it is imperative that the driving power be increased. In fact, hypertrophy is compensatory, and enables this to be done; and where there is this hypertrophy, the patient himself may not be conscious that any morbid change has gone on in him. In fact, between hypertrophy and dilatation again does the balance rock, and with it the prognosis; in hypertrophy, as long as it can be maintained, the patient's chance of life is a good one; in dilatation the aspect is clouded, and an artificial hypertrophy must be attempted. Artificial hypertrophy is no therapeutic fiction, and can be produced by more or less time and perseverance, in

a great many cases, by administering agents which produce a better ventricular contraction, and a system of nutritive support; for the law of increased action being followed by increased tissue nutrition in normal texture is unalterable, if healthy blood be furnished. The good effect of change in the muscular walls in regurgitant valvular disease is not at first sight so perceptible as in regurgitant mitral, for instance, where the question is far from an uncomplicated one. No observer of much experience will have any difficulty in recalling numerous instances of mitral regurgitation with hypertrophy, or dilatation, or both, of the left ventricle, and where the ventricular change is consequent. Let us see how, where no drug has been administered, the system's power of repair has set up compensatory changes. Valves, it must be remembered, are not found in hearts of the lowest grade, and are only belonging to complicated and involved hearts; the primitive heart is a mere "pul-satile sac", a thickened and dilated section of a tube. So, when the valves are injured, the heart is reduced to a lower type; that is, the muscular walls no longer get that aid from the valves to which they have been accustomed, and consequently augmented work and increased growth are entailed. In fact, the muscular structure is no longer aided by this beautiful mechanical contrivance, and so change in itself is necessitated. The blood is no longer thrown forward into the aorta at each ventricular systole completely, but a portion regurgitates through the imperfect auriculo-ventricular valve, and thus overloads the venous system behind. The pulmonic system and the right ventricle undergo compensatory changes of dilatation with thickening; the power of the pulmonic system, in fact, is generally increased; the blood pours into the left ventricle on its diastole, under greater pressure, and thus distension of it follows, with hypertrophy or dilatation as its usual concomitants; the usual question of restorative power of the system deciding whether. The consequence of this change is one little to be expected by any one who has not given the subject of compensatory changes its proper consideration. It is this; that, in spite of the regurgitation of a considerable amount of blood, it (the ventricle) remains capable of filling the aorta (Niemyer). That it does so with more or less success is evidenced by the irregularity of the pulse—not irregularity in time, but irregularity in volume, sometimes nearly the whole amount of blood passing forward, and then again a great portion passing backwards. But to achieve this change in the left ventricle, increase of growth behind the lesion is unavoidably necessary; without the opposition of the blood in the pulmonic system, and the hypertrophied right ventricle, this would be unattainable. Thus we see that muscular change is compensatory in regurgitant disease behind, as well as obstructive disease before.

Sir Dominic Corrigan considered the advantage of administering digitalis (and the fact of relief being afforded by it as unquestionable, however defective the explanation) to lie in its rendering ventricular action slow. Thus in aortic obstruction it allowed the ventricle more time to perfectly empty itself into the aorta; that is, compensation took place by more time being allowed for the passing of the blood into the aorta through the narrowed orifice. The objection to this theory lies here: there is a diastole as well as a systole, and a prolonged systole must necessitate a shortened diastole, or no compensatory good can accrue. For the ventricle must be filled before systole, and that requires time; so that if the advantage lies in the retardation, it is difficult to see how it is any advantage. There must, on this explanation, be so many fewer contractions in the minute, and the wants of the system would be as unsupplied as ever. It is not, and cannot be, a question of time, but of power. What comes of the hypertrophy which occurs in obstruction? To what is it compensatory on the theory of time? After the ventricular action has been rendered slow, the hypertrophy ought to pass away, as it does in a parturient woman. Whether it does so or not, I cannot tell, as I have not found the pulse made slow in aortic obstruction in my experience. So in mitral obstruction it was supposed to be beneficial by allowing the auricle more time to empty itself into the ventricle. But, unfortunately, the same objection meets us here, and, further, the ventricle is nearly full when the auricle contracts. It is the distension of the auricle which evokes contraction; its contraction produces distension of the ventricle, which distension then provokes ventricular contraction, but the ventricle is nearly full when the auricle contracts. In mitral regurgitation, the retardation could have no good effect. The question is not one of time, but of power. In obstructive disease, a simple hypertrophy enables the ventricles to throw an equal quantity of blood through a narrowed space in a given time. In order that an equal quantity of blood may be driven through a narrowed orifice in an equal time, we must have increased power. No other arrangement could possibly achieve the result. In regurgitant disease, the question is not nearly so simple; and in order to comprehend exactly how digitalis can give relief in mitral regurgitation, a digression for a little time is absolutely necessary, so that we may review the changes which the

normal conservative power of the system, unaided by art, can produce; and it is in imitating or assisting these changes that we can alone hope to be of service. The effect, then, of mitral insufficiency is regurgitation into the pulmonary veins. The lung-space is unduly filled with blood, and therefore has not sufficient space for air; hence the dyspnoea commonly found as a symptom of this lesion. The circulation is impeded, and the blood is imperfectly aerated, and flows less readily into the pulmonary veins from the capillaries.\* Thus there is further tendency to pulmonary engorgement and obstructed flow. This impediment to the flow of blood from the right ventricle entails in it changes. The right ventricle becomes dilated and hypertrophied. First there is dilatation, and then hypertrophy comes to the rescue. The overloading of the pulmonic circulation leads directly to changes in the muscular walls, and again the battle of life or death rests on the power of self-growth in the involuntary muscular fibre. If the yielding lead to degeneration, sudden death is the probable result at no distant period; if to a lesion in the tricuspid, then the stress falls back on the veins, and dropsy results, with all its train of troubles. The temporary effusion through the walls of the veins or venous capillaries often gives great relief to the patient; in fact, the blood, overlaid with water, is relieved of part of its burden, the overcharged circulatory system is somewhat eased, and the improvement of all the systemic symptoms is consequent. But it has added another trouble in the future, and the passing relief is embittered by the reflection that it is a mere bill of accommodation that will soon be due again. The relief to the distended venous and pulmonic systems sometimes admits of their recovering themselves to some extent, but this is unfortunately only a rare occurrence. Dropsy, that is effusion from distended capillaries, is also taking place into the pulmonary tissues, and pulmonary oedema increases the patient's woes; blood even may be effused when the distension is great, and there is no more alarming consequential symptom of mitral regurgitation than hæmoptysis. The stress on the systemic veins directly affects the systemic circulation, and increases the stress on the left ventricle; increased difficulty of flow is superadded, and the pulmonary engorgement is redoubled. In addition, the liver is gorged, and the spleen distended; the kidneys are in a condition of asthenic congestion, and the pressure on the glomeruli is lessened; thus the flow of water by dialysis is interfered with, and the bulk of urine radically lessened; and thus we have an extended circle of mischiefs aiding and abetting each other, acting and reacting till it becomes difficult to ascertain the starting point. This is no exaggerated or even highly coloured picture of the condition of the patient suffering from mitral insufficiency and its consequences. But against this train of troubles must be set the power of hypertrophy in the right ventricle. If there be sufficient compensatory change, then all this may be arrested for a long period of time. Increased activity of the right ventricle gives relief to the general symptoms. The blood pouring into the left ventricle under greater pressure, and its reflux being opposed by a greater *vis a tergo*, more blood is thrown into the aorta, and thus better aortic distension follows the muscular activity as a necessary consequence. Thus the action of digitalis on the right ventricle is of the utmost importance, while its effects on the capillaries aid in sustaining the increased pressure on the pulmonic circulation. By its use, we aid that natural thickening and increase of substance which the system spontaneously sets on foot on its balance being disturbed. In some conditions, aid is unnecessary for years, or may only be required during some debilitating action, but it must never be withheld when a trying affection like bronchitis is testing to the utmost the patient's power of resistance. In other cases where the natural efforts are visibly unequal to the demand, and the struggle is being abandoned, the aid we can furnish may be less effective, and the restoration of balance more imperfect; still it is worth the trial, and tends to prolong the existence of the organism. We must never forget that, in regurgitation through the mitral valve, the condition of the right ventricle and its allies is the only hope of the physician. It is, then, to the action of the right ventricle that we must look for assistance when trouble is due to the mitral insufficiency; and it is by augmenting the contractile action of the ventricular fibres, and its effect on the capillaries by opposing their distension, that digitalis can be useful in mitral disease; for the troubles of mitral obstruction are those of mitral regurgitation. It is to the loss of compensatory action, or, rather, the inefficiency of it, that we must attribute the want of success in our treatment of tricuspid regurgitation. The increased action of the right ventricle is not lost over the short length of the pulmonic circulation, while the increased action of the left ventricle is lost over the length of the systemic circulation, and therefore exercises no useful effect in opposing the regurgitation of the blood in tricuspid insufficiency.

[To be continued.]

\* The question of the readier flow of blood containing oxygen is not one to be entertained here.

## HOW TO REFORM OUR PROFESSIONAL GRIEVANCES.\*

By W. OGLE, M.A., M.D.Cantab., F.R.C.P.Lond., Physician to the Infirmary, Derby.

*Concluded from page 31 of number for July 8th.*

AND now, gentlemen, what have been the remedies proposed? and how far are you prepared to sanction them? It is with some satisfaction that I can say, more has been done of late years for the parish doctor, more for the pauper patient, than for any other class. For the club-doctor and the club-patient nothing, or worse than nothing, has been done. In general practice there have been some important changes in the right direction, but they are few; whilst physicians' practice has been, I fear, going either downward, or at best but "standing still"; whilst progress has been made in other departments; and in the moral and social world, no less than in the physical, this is tantamount to retrogression.

To physicians, therefore, and to all who aim at first-class practice, I would specially address myself. The changes in other departments are full of instruction to you, and this is the thing to be noted—so far as the patient has been made the first consideration, so far has real and substantial relief been accorded to the doctor. Many well-intentioned efforts towards reform have come to nought from their one-sidedness. There can be no question that Mr. Griffin's praiseworthy and self-sacrificing endeavours in behalf of parish doctors would have been more completely successful, had he put forward more prominently the sufferings of pauper patients.

So again in club practice; nothing, or worse than nothing, has been done. The strike at B—m two years ago, with the rattening of those who would not join, was worse than nothing. However much one might sympathise with the doctors, and feel that the attempt on the part of the club to reduce their pay was unjust and ill-advised, one could not wish well to the one-sided, unprofessional, patient-forgetting, measures of defence. He that can say only *il faut vivre*, will get nothing more, and deserves nothing more, than *je n'en vois pas la nécessité*. In private practice little has been done directly, but there has been indirect movement—movement full of promise, if advantage be taken of the situation, but not without its dangers, for there is a general restlessness which is incompatible with security. To make the building firm some further attention to the foundation is necessary. But, as already intimated, it behoves physicians, most of all, to bestir themselves. The only hint that I can catch of relief to physicians is that which has often been whispered, and just now has been spoken with authority. A committee has been at work in London during the winter, and has issued a very valuable report. Among the recommendations there are three which I cordially approve; but a fourth, for the relief of young physicians, to give them an honorarium for their attendance in the out-patient room, is very questionable. The proposal is so fraught with danger to our professional character, and so obviously leaves the patients *in statu quo*, that I take this early opportunity of saying, "Save me from my friends". What, then, is to be done? I venture very earnestly to submit that the time is come when something ought to be done; and I think public opinion gives indications of preparedness for something, if only comprehensive measures on thoroughly sound principles could be devised.

Time will not permit me to give more than a sketch of the line of action which seems to me most promising. A very first necessity is, whilst listening to every grievance, to take an independent position, and to look at the profession as existing not for itself—*non sibi sed toti*. Consider the profession teleologically, as a portion of the body corporate, charged with the performance of certain duties peculiarly its own. See to it that every measure of reform has this object distinctly and primarily in view—that it is to enable the profession to do its duty better. The prevention and cure of disease, the prolongation of life, and the alleviation of suffering, are, in a few words, a summary of professional duty. Let the ground-work of our reform be this—a confession of shortcomings. We need not fear to acknowledge that there is more physical suffering than used to be, considering the present state of medical science—that life might be more prolonged than it is, that more cures might be performed, that much more sickness and many more deaths might be prevented.

The Registrar-General furnishes a statement week by week which leaves no doubt as to the fact that much more might be done than is done. I hail with much satisfaction, as showing still more plainly what work is still undone, the disease charts of Mr. Haviland. He has pub-

lished maps of the country, coloured in such a way that the eye perceives at once the registration districts in which mortality is in excess of the average, and that in which the mortality is below. Figures pass through the mind and produce little or no impression, but that which is seen is easily remembered. In these maps the healthy districts are painted red, in three shades—good, better, best; and the unhealthy in three shades of black—bad, worse, worst; so that any one can see at a glance what is the sanitary condition of his town and neighbourhood. If these maps could be published periodically, and hung in some public room in every town in the kingdom, it could hardly fail but that the work of the prevention of disease would secure more attention. People would not be satisfied to see Derby, for instance, painted black when Leicester was coloured red. I wish, therefore, to submit to you the possibility of our engaging in the work of prevention much more decidedly than has ever yet been attempted; and the bearing of this proposal upon my subject is very close, for I shall put my proposal to this very searching test of its merits. I shall propose it not merely as worthy in itself of your consideration, because of its preventive character, but also because it would tend more or less directly to the removal of every one of the grievances that I have already specified. I advocate a reform from *within*; and I am bold to declare that it would do more to place the profession in its own proper position of dignity than any Act of Parliament, however well devised, or indeed any measure of reform commencing from *without*.

This, then, is the practical conclusion which I wish to bring before you. Let the family doctor be a health-officer, whose first duty is to prevent disease; let his relation to the family be such that it is to his interest to cure disease, not prevented, as quickly and as thoroughly as possible; let him delegate the sale of physic, and the dispensing of it, whenever it is possible, to druggists. I submit that this might be done by arranging that the acknowledgment for his services should be so much per annum for all *ordinary* work, leaving a good margin for supplementary fees for *extraordinary* visits. The Chinese system of paying the doctor when the Emperor is well, and cutting his head off when his Highness dies, has often furnished point to a joke against the profession. Let us extract the sting by adopting the sound principle, which is nothing more than that embodied in the proverb, "Prevention is better than cure." The only difficulty that occurs to me as worthy of mention is that of determining how much the annual sum should be, or rather, I should say, how little, for it must be comparatively small to secure general acceptance; and I think it might fairly be so, in consideration of the relief given in other ways, and specially by the proviso made that there are to be supplementary fees for all extraordinary acts of service. The distinction between *ordinary* and *extraordinary* services might easily be made: for instance, ordinary service would include, as a matter of course, everything that the doctor can do in the way of prevention; and, to make the preventive service complete, it must also include a great deal of what is commonly called general practice, but it need not and ought not to include everything. For instance, it ought not to include night-visits—at least not such as are specially requested—nor Sunday visits specially requested, nor visits in obedience to a summons to come either immediately (as to an accident or to a confinement) nor to attend at some particular time specified by the patient (as for a consultation). These are all exceptional acts of service, and for these a fee should be demanded over and above any annual sum that might be agreed upon. All other work, even though it should amount to an attendance through a long illness, might be covered by the annual sum, subject to readjustment at the close of the year; all work, in fact, for which request has been made at an early hour—say by the time of the first postal delivery—and for which it is an understood thing that the doctor is at liberty to call or to send a substitute at whatever time in the course of the day is most convenient to himself. On the other hand, extraordinary visits for which fees are to be paid would be, as already stated, night visits, but of these only such as are specially requested—Sunday visits specially requested, visits in obedience to messages to come "immediately", or at some particular time named by the patient.

And now, gentlemen, for the crucial test proposed. What would be the effect upon our grievances of such a change—shall I say such a revolution, in medical practice? What would be the effect upon the doctor's grievances? what upon those of the patient? Take, first, the family doctor—family physician, if you please, for he would be entitled to claim in virtue of his office the highest title possible. He would be freed from all trading accessories; he would have no pecuniary interests in the physic, much or little, that his patient took; nay, even in regard to visits, he would have no trade stimulus, but only those that are strictly professional; he would visit his patients just as often and just as seldom as he felt was good for them. The protection of the patients would be that the sooner they got well and the longer they remained so the better

\* President's Address, delivered at the annual meeting of the Midland Branch, 1871.

it would be for the doctor. The doctor's bills would now no longer be questioned, for "particulars" would be given in full—they would simply be fees for extraordinary visits. He would also know, as a general rule, what was his day's work by breakfast time; and, this work being done, he would not only be comparatively free, but would have the very great comfort of feeling so; and when a summons did come he would be sure that it was not a mere whim of some inconsiderate or fanciful patient: whims and fancies would at least be reduced to a minimum if the doctor's house were surrounded by a cordon which could only be broken by a golden key. I anticipate, farther, that the relation between the doctor and the family would be immensely improved, and that he would no longer be a "servant" and his patients "slaves"; their relation to each other would be that of "friends", and it would be much less liable to disturbance. People would, no doubt, be more careful, and take a longer time in making their choice of a doctor, but, having made it, would be less likely to change.

Turn, now, to the condition of the patients: their grievances have vanished into thin air. Their interest has been put first, and it coincides so entirely with that of the doctor that there is no room left for suspicions and misunderstandings. Again, under such a system, club-doctors would cease to exist, for the annual sum for ordinary work would obviously admit of graduation far more easily than is possible in charging per visit or even per bottle.

Club doctors—at least men with duties such as are now expected—would not be wanted; possibly such officers might be appointed, but their duties would be different. The payment would still be small, but the service demanded would not be great: their duties would be to look after the interests of the club, to protect it against the admission of unhealthy members, and against ill-founded declarations against the funds of sick members, and to perform other such general and highly honourable service. The power of combination for such a purpose as to provide medical aid may be inferred from the extraordinary results obtained by two or three of the provident dispensaries, in which the benefiting members contribute so small a sum as 1d. a week, or 4s. 4d. a year. From the fortieth report of the Derby Provident Dispensary, it appears that members of this class contribute more than £1000 a year. If so much can be done by pennies, how much more might be done if arrangements on a better plan could be made for the twopenny, threepenny, etc., class? Let the provident, or, as I would rather say, the preventive principle, have full play, and imagination could hardly say too much as to what might be achieved.

Forty years ago, Mr. Jones of Derby and Mr. Smith of Southam had the sagacity to perceive and the benevolence and courage to make the experiment with the least productive element; and, though the result is not such that I can conscientiously recommend you, now in 1871, to adopt their plan, it is abundantly sufficient to show the soundness of the principle upon which they acted, and further to prove that it needs only that we trust those principles more thoroughly to realise still greater results—greater in every way, both commercially, and, more important still, greater in the sense of being more thoroughly efficient and free from certain professional faults which have, no doubt, been a principal cause why provident dispensaries, even where most successful (as at Coventry, Northampton, and Derby), have never attained to anything more than mediocrity. All honour, however, be to Mr. Jones and to Mr. Smith for having done so much; anything that we do will be by standing upon their shoulders.

I see no reason to doubt that, in a well-managed local association, five or six medical men working together under a well constituted representative board of management, the working classes might provide themselves with thoroughly efficient medical aid, including even payment for their admission when necessary into hospitals, and including many other things which at present are beyond their reach. Those arrangements would bring relief more or less directly to the whole profession, but primarily to those who are connected with hospitals. A better system of attendance for the working classes at home would relieve these noble institutions very much of the routine work which overwhelms them; and if arrangements were made for members of such associations to pay for admission, hospitals would be relieved financially—they would become gradually more or less self-supporting. When this comes to pass, but not till then—that is, when patients are admitted on their own right by payment—can I look with anything but jealousy upon the proposal to give salaries to any portion of the medical staff. Meanwhile, relieve us of all work that ought to be done by the parish—of all work that might be done outside the hospital; put us in a position to attend exclusively to urgent cases, and we will ask no more. This will require from the public no little sum of money. We have ourselves spent recently some £20,000 in altering (would that it had been in rebuilding) our Hospital. When I ask for this as a necessary expenditure, I do in effect ask for a sum which, if capitalised,

would have produced £800 a year. The medical staff might have received this for their services with a clear conscience; but, I ask my colleagues, had the Hospital remained as it was ten years ago, with this difference, that we were now in receipt of £200 a year each for our services, should we, as professional men, have been in as good a position as at present? I repeat, all that honorary medical officers ought to ask at present in return for their services is protection against the admission of improper cases, and that every facility possible should be afforded to enable them to do their work thoroughly well. As to what I will call first-class practice, independent of that in connexion with hospitals, I would simply ask that the physician or surgeon be left to take care of himself, and that attention be directed entirely, or at least primarily, to the improvement of the character of the service. A consultation at present is a very unsatisfactory proceeding to all parties. It lacks that first element of satisfaction, in that no care is taken to secure that the second opinion shall be formed independently. On the contrary, the first thing done is for the doctors to talk the case over privately: this makes it impossible for the second to form a perfectly independent opinion, and this mars the whole proceeding. That which I should wish to do, and to be compelled to do in any case wherein my opinion was desired, is to examine the case thoroughly for myself. This, done, I am prepared to meet the family doctor and to consult with him and then the patient obtains the benefit of two opinions; and two heads are better than one. As things, however, are at present, the family doctor paid per visit and per bottle, and the doctor called in paid in the same way, this freedom of action is almost impossible; but, if the family doctor were paid *per annum*, the difficulty would be lessened, if not entirely removed.

Did time permit, I might easily show the effect of such an arrangement upon counter practice, and on quackery, and on special practice, which is often but a disguised form of quackery; but I have already detained you longer than I ought to have done. It remains, therefore, for me to thank you for your patient and indulgent attention, and to conclude by giving you a most cordial welcome to Derby. By the kindness of the Weekly Board of Management, we meet in this room. I regret that time will not now allow me to show you over the Hospital; but be assured that at any time when business or inclination may bring you to Derby, we, the honorary medical staff, shall be prepared to receive you as brethren, and to show you what has been done; and, for myself at least, I will add, not merely to act as your guide, but to look for instruction from your visit. If any should think that the views herein so imperfectly set forth are worthy of further consideration, I shall count it no less my privilege than my duty to confer with them further, and to give any assistance in my power to towards putting them into practice. I shall also ever receive with respectful attention all remarks (publicly or privately expressed) from those who differ from me; whilst to those who agree with me I will only offer a word of caution against being too sanguine of speedy success or of personal gain. Evils such as I have enumerated can only be removed very gradually; work such as remains to be done must be encountered with a single eye, and, by God's help, in the spirit of the "Iron Duke", who used to say in the face of every difficulty, "I know nothing of difficulties, but that they are things to be overcome".

## ON THE THEORY OF DISINFECTANTS.\*

By T. P. BLUNT, M.A., F.C.S.

THE light which has recently been thrown upon the nature of contagion and infection by the labours of Pasteur and others, the results of which have been ably summarised by the President of the British Association in his late inaugural address at Liverpool, seems to point the way to clearer and more comprehensive views than those commonly entertained at present regarding the operation of the substances known as disinfectants.

These may be divided into two classes: 1. Those which act by the oxidation and total destruction of the virus contained in infected matters, together with the foul gases which usually accompany it, and which are, in fact, Nature's danger-signals of its presence. 2. Those substances which do not possess the active chemical properties of the first class, yet are proved by experience to have a similar power of arresting and checking the spread of infection. The latter are, for the most part, the more ancient and popular, having apparently in some cases been suggested by a just but unreasoning instinct. Thus we find that the use of sulphurous acid, as evolved from burning sulphur, dates even from Homeric days; while the burning of pitch and

\* Read before the annual meeting of the Shropshire Scientific Branch.

aromatic gums for disinfectant purposes has an origin at least equally remote.

An attempt will be made, in the course of the observations which follow, to bring the operation of the large majority of the latter class under a general law which shall furnish us with an explanation of their true character. This is especially desirable, since it is to be feared that, for want of such an explanation, many good and valuable disinfectants have been condemned by chemists, on theoretical grounds, as mere deodorisers—not assailing the virus of infected substances, but rather masking their poisonous character by precipitating their offensive gases. An objection to this view at once meets us, in the utter disproportion between the volume of the gases to be fixed and the quantity of salt practically found sufficient for the object required, while it breaks down altogether when applied to such disinfectants as the new “chloralum” or chloride of aluminium of Mr. John Gamgee, or the well known carbolic acid. Before endeavouring to supply a more probable theory, it may be well to remind you that the researches already mentioned have established the fact that contagion and putrefaction, if not actually identical, are processes so closely allied that they require exactly similar conditions; the latter appearing to consist of a kind of disease propagated from particle to particle of a decomposing substance, and ending in its entire destruction. Hence it may be inferred with perfect safety, that any agent which arrests putrefaction is capable also of abolishing the properties of contagion and infection.

This conclusion at once puts into our hands a valuable instrument of research; for while it is difficult, and often impossible, to investigate directly the disinfectant action of a substance, the inquiry being surrounded by innumerable sources of error, the properties of an antiseptic are perfectly well defined, and open to the clearest demonstration. Thus, in the case of the two bodies mentioned above, carbolic acid and chloride of aluminium, the antiseptic action of the first is well known, and has long been usefully applied; while that of the latter is maintained in the most positive manner by its introducer, Mr. John Gamgee, who certainly brings forward overwhelming proof of it in his recorded experiments upon meat and fish; and hence, on the grounds given, we are justified in regarding these substances as good and useful disinfectants. It may be stated, in passing, that the deodorising power which these and other similar bodies possess is probably due to their antiseptic action; the offensive gases of decomposition being sooner lost by diffusion, and their fresh production being entirely suspended.

Let us now proceed to a consideration of the origin of the remarkable properties which we have described. This appears to have been traced with some degree of probability, in the case of carbolic acid, by Dr. Joseph Hirsch, the writer of an article which appeared in the *Chemical News* about the end of February 1869. He advances the bold and ingenious speculation, that the disinfecting action of that substance depends upon its power of coagulating albumen. He supposes that the acid finds its way into the minute organisms, which propagate disease by diffusion through their investing membrane; that it coagulates the albumen which they, in common with all germinal matter, contain as a necessary constituent; and thus practically destroys their vitality as perfectly as immersion in boiling water terminates that of an egg.

In order to test the accuracy of the view thus enunciated, I selected a substance of which the albumen-coagulating power was well known, and examined it with regard to its antiseptic, and therefore disinfectant, properties. The substance chosen was nitro-muriatic acid, which has long been in use as a test for albumen in urine. The experiments were conducted as follows.

a. Two samples of fresh healthy urine, passed at the same time, each measuring about one ounce, were placed side by side. To one of them six drops of strong nitro-muriatic acid were added. In a few days, the unacidified specimen was covered with a thick crust of mould; while that to which the acid had been added was unaltered, except by a slight darkening of colour and deposition of crystals of uric acid.

b. Some fresh meat was pounded into an emulsion with water—the whole divided into two equal portions of about six drachms each. To one of them six drops of strong nitro-muriatic acid were added, as in the former case. In a day or two, the unacidified sample was quite putrid and offensive; while that to which the acid had been added retained the smell of fresh meat, and continues to do so still, after the lapse of nearly a month.

I now proceeded to test some of the salts commonly used as *disinfectants*, with respect to their possession of this power of coagulating albumen. The examination was conducted thus. One part of the salt to be tested was dissolved in one thousand parts of distilled water, and the solution was mixed thoroughly with the fresh white of egg. The salts examined were iron alum, sesquichloride of iron, common alum, chloride of zinc, and nitrate of lead. Coagulation fol-

lowed immediately in every instance. In one or two cases, the dilution was carried much further—one part of the salt to three or four thousand of water. Here, too, coagulation followed in one or two seconds.

It may be remarked, in passing, that the hæmostatic action of the iron-salts is probably to be attributed in great measure to this faculty of coagulating albumen, exercised upon the serum of the blood.

The attempt to obtain similar results from the sulphites entirely failed. They appeared, indeed, to retard coagulation by other reagents. The coagulating power of sulphurous acid was faint and ill defined.

If we review the evidence now before us, we shall find that it stands thus.

We start with two assumptions—the first justified by recent research, the second borne out by analogy; viz., that infection results from the transference and development of minute germs; and that these germs contain albuminous matter as a necessary constituent, the coagulation of which terminates their existence. Upon these assumptions we frame our major premiss—that “all coagulators of albumen are disinfectants”; and, having arrived at this result by a process of pure reasoning, we proceed to prove its truth by experiments upon the antiseptic, and so upon the disinfectant, properties of a well known albumen-coagulator. Having thus established our fundamental proposition, we produce experimental proof of our minor premiss—that “nearly all the substances to which popular experience has assigned the property of arresting the spread of infectious diseases, where that power is at present unexplained, are coagulators of albumen.” The conclusion then necessarily follows, that these substances are disinfectants; and thus a vindication of their efficiency is furnished in those cases where it has been called in question by chemists on the ground that no sufficient explanation of their action had been offered.

The above conclusion does not apply to sulphurous acid and the sulphites. In their case, we must probably look for some more remote physiological effect upon germinal existence.

#### *Note on the Use of Hydrochloric Acid as an Antiseptic.*

It is probable that hydrochloric acid, which shares the properties attributed to nitrohydrochloric acid in the foregoing remarks, will be found to be a valuable preservative of animal food. A piece of meat, immersed for fifteen minutes in a mixture of one part of the acid to three of water, remained entirely free from putrefactive change after nearly a fortnight, though the action of the acid was not sufficiently powerful to prevent the appearance of a small quantity of mould. The meat was then immersed in a dilute solution of carbonate of soda, and the superficially absorbed acid was thus converted into common salt. This reaction obviously gives hydrochloric acid a great advantage over other antiseptics, which introduce into the food a foreign substance, inimical by its very nature, in most cases, to the process of digestion.

## GYNÆCOLOGICAL NOTES.

By ROBERT BARNES, M.D.,

Obstetric Physician, and Lecturer on Midwifery and Diseases of Women and Children, at St. Thomas's Hospital.

### IV.—SUDDEN DEATH IN PATIENTS SUFFERING FROM CANCER.

PATIENTS suffering from cancer of the uterus or ovaries not unfrequently die suddenly. The causes of this event have not attracted much attention. The late Dr. Todd (*Clinical Lectures*, Beale's edition) remarked that death may occur suddenly from malignant disease in the abdomen, as of the peritoneum. He was of opinion that cancerous matter passes suddenly into the circulation, causing prostration by poisoning, as in pyæmia.

There can be little doubt that, in some cases, where cancerous growth invades the walls of blood-vessels, portions may be detached and then swept into the circulation. I have, however, searched for these cancer-emboli without success in cases where the final symptoms seemed to point to pulmonary embolism; but in a woman suffering from encephaloid disease of the ovary and uterus, who recently died suddenly in St. Thomas's Hospital, my attention was fixed upon a condition which, I think, accounts for the catastrophe by a mechanism altogether different from embolism.

A woman aged 60 was admitted with the usual symptoms of cancerous cachexia of some duration. I found the pelvis filled with the morbid growth, involving uterus, vagina, rectum, and bladder, in one mass. Rest and good diet seemed to improve her condition; but one day after being about she complained of difficulty of breathing, quickly became collapsed, and, without losing consciousness, died in a few minutes.

The mode of death, as it was reported to me, made me surmise cardiac or pulmonary embolism; and at the autopsy, careful examination was made to verify this conjecture. Nothing in the nature of embolism or thrombosis was found; there were, however, extensive secondary cancerous deposits or growths in the abdomen and chest. The pelvic peritoneum was studded with small cancerous nodules; others were scattered over the liver and spleen; the left psoas muscle was involved. The glands and subperitoneal tissue in the lumbar region and the vicinity of the left kidney were involved in dense masses of cancerous tissue. A condition which struck me was that the diseased glands, lymphatics, and connective tissue around the aorta and vena cava, made one compact solid mass from the pelvis to the diaphragm, in which the aorta and vena cava ran like tunnels bored through unyielding substance. In many places the coats of the aorta were bent inwards, forming nodular projections into its channel. The result was that the aorta was no longer an elastic tube, expanding under the heart's systole and then contracting, but a rigid tunnel, utterly wanting in resiliency, and with its interior no longer smooth, but distorted by irregular projections.

Such an aorta, accompanied by a vena cava similarly affected, is mechanically unfitted to do its work. Under very moderately increased exertion or emotion, causing unusual action in the heart, this rigid tube would throw back upon the heart a portion of the column of blood which the aorta ought to receive and propel. This retrograde dynamic disturbance would overwhelm the feeble heart, and thus death would follow.

In another case, where the ovaries were involved in malignant disease, and where secondary growths were found in the intestinal peritoneum, the patient, coming from the country during cold weather, died next day, almost suddenly, overpowered by dyspnoea. The pericardium and both pleuræ were found distended with recent effusion of blood-stained serum.

These cases show that to prolong life the strictest care should be taken to avoid excitement, exposure, or exertion.

#### CASE OF PERITYPHLITIS.

By MARSH JACKSON, M.R.C.S., SMETHWICK.

E. P., aged 24, a spare, active, steady man, of a nervous disposition, had always had good health till within the nine or ten months before I saw him; during which time he had suffered from "indigestion", irregularity of the bowels, flatulence, and occasional hiccup. I first saw him on March 9th, 1871. He then complained of great pain in the right inguinal region, about the umbilicus, and down the right thigh; the testicle was retracted. On examination, the pain, which was exquisite on both the slightest and on continued pressure, was especially referred to a line about an inch and a half above, and parallel to the crest of the ilium, extending almost from the edge of the quadratus lumborum to within two inches of the pubes. There was no swelling, but a distinct hardness could be felt, and there was dulness on percussion along that line. He was in bed, and lay on the right side, with that thigh flexed upon the abdomen; the slightest movement increased the pain. The bowels had not been moved within the last twenty-four hours. The tongue was furred and moist; the breath had a fecal odour. There had been some vomiting. The heart and lungs were healthy. The urine was abundant, and, on being tested, gave no special indications. He had had no rigors. Pulse 92; temperature 100.2 deg. Fahr.; respiration 24. The treatment consisted of hot linseed poultices to the side; a pillow to support the right knee; one grain of opium every four hours; an injection of castor oil. The diet was milk, beef-tea, eggs, etc.

I saw him at 8 A.M., and between 7 and 9 P.M. each succeeding day, till the 13th, during which time the above symptoms remained pretty constant. On the morning of the 13th, the pain was most acute, and had extended more round to the back, up to between the scapulae, to the buttock, and down the side of the thigh. There was a marked line of swelling along the line described above, and here the pain was most acute. I ordered six leeches to be applied over the swelling, and increased the frequency of the doses of opium. In the afternoon, I saw him with Dr. Heslop, who concurred as to the diagnosis and treatment. In consequence of the pain having abated somewhat, the leeches had not been applied; and Dr. Heslop advised their immediate application, thinking they would relieve the local congestion, though suppuration was a consequence to be feared. Notwithstanding daily injections of castor oil, the opium had confined the bowels too much, and Dr. Heslop recommended in addition to them a daily small dose of castor oil by the mouth. The next day he was much easier; the leeches had drawn a fair quantity of blood. He had passed two pale lumpy motions,

though with great pain, and was very feeble. Temperature 38.3 deg. On the 15th, he had had a most restless night, and had been delirious. The pain was much worse, and the swelling more marked than it was the previous day. He had had no rigors. Pulse 100; temperature 102.9 deg. Fahr.; respirations 28. Six fresh leeches were ordered to be applied. At 8 P.M., the pulse was 96; temperature 101.5 deg. Fahr.; respirations 28. The leeches had drawn well. The pain had almost gone: considerable pressure could be borne. The swelling had subsided very much. The opium was ordered to be discontinued altogether, and a dose of castor oil to be taken in the morning.

On the 16th, at 8 A.M., the pulse was 100; temperature 103.3 deg. Fahr. Respirations 28. He had passed a restless night. The intestines were distended with flatus; the bowels had not yet been moved. At 7.30 P.M., the pulse 80; temperature 101.1 deg. Fahr.; respirations 28. The bowels were moved during the morning; after a free motion, he broke out into a profuse perspiration, and had several hours' sound sleep. He was in no pain, and for the first time could straighten the leg.

Next day, the temperature was 100 deg. Fahr. From this date he progressed towards complete recovery; the induration disappeared; and the bowels acted spontaneously. He sat up dressed on the 20th, and I ceased to visit him on the 23rd. He was taking quinine, and ate with a good appetite.

On May 1st, he called on me, quite well. Till within the last fortnight, he has felt a slight soreness on receiving any jar, as coming down stairs, or stepping off the curb-stone. Now he has lost this feeling, and looks robust and strong.

The specially interesting features of the case are the steady persistence of so high a degree of temperature, the marked benefit resulting from the use of leeches and castor oil, and the speedy and complete recovery.

#### CLINICAL MEMORANDA.

##### CHLORAL IN DELIRIUM TREMENS.

AMONG the many communications respecting the use of chloral in delirium tremens, I do not remember any mention of an antagonism to the action of this drug such as that manifested in the following case. On the afternoon of the 1st instant, I was called to see a man, aged 25, who was fast lapsing into delirium tremens. He had not then any delusions, but he had been sleepless for two nights, was excessively restless, and for twenty-four hours had vomited everything taken; a mixture containing chloral in small doses being always rejected the moment it was swallowed. In place of this, I ordered him a mixture containing hydrocyanic acid and morphia, which he took, with much relief to the gastric irritability; that night he had two hours' sleep, and three more in the afternoon of the following day. On the evening of the 2nd, he seemed much better, and presented a fair chance of escaping the worst features of the disease. He had, however, a very restless night; and the next morning, being without proper control, he got up and wandered about the house and neighbourhood; in the evening, all the phenomena of the disease in an aggravated form were present. Chloral having been at an earlier stage so intolerable to the stomach, I was unwilling to return to it, and ordered him bromide of potassium in thirty-grain doses every hour, in the hope of allaying his great violence and excitement. Three doses were taken without any mitigation of his symptoms; and at midnight I ordered a draught containing eighty grains of chloral, one half to be given at once, and the remainder in an hour and a half, if sleep did not come on. Both doses were taken and retained without producing any effect; and he spent the night in a state of great excitement, requiring the continuous exertions of two men to keep him in bed. At 8 A.M., a draught containing sixty grains of chloral was given; sleep came on in a quarter of an hour, and lasted for two hours. He then awoke, certainly much less violent, but the delusions and restlessness were as bad as ever. Pulse 120, small and feeble. This state of things continuing until 2 P.M., he took an additional sixty grains of chloral, and, between 4 and 5 P.M., being still restless and sleepless, another sixty grains. He fell asleep about 5 P.M. He woke up two or three times during the night and took nourishment, but went quietly off to sleep again. The next forenoon he was quite rational, and free from his complaint; pulse 88, comparatively full and strong. In rather less than seventeen hours, then, this patient took two hundred and sixty grains of chloral before curative sleep was induced. He had no vomiting for the last twenty-four hours of his illness, and during that time he partook freely of a solution of Liebig's extract of meat, to which whipped white of egg had been added.

GEORGE F. ELLIOTT, M.D., Physician to Hull Infirmary.

# REPORTS OF MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS OF GREAT BRITAIN.

## NOTES ON THE TREATMENT OF GANGLION IN THE LONDON HOSPITALS.

[Continued from page 33 of last number.]

We have received the following additional particulars from the two following metropolitan hospitals.

### UNIVERSITY COLLEGE HOSPITAL.

Ganglion at the wrist Mr. BERKELEY HILL never forcibly ruptures, but evacuates subcutaneously by first incising the sac freely with a tenotome, then squeezing out the contents of the sac, and firmly pressing the walls together with a compress and strap of plaster. Should it recur, a fine silk thread is carried through the swelling with an ordinary suture-needle, and left for three or four days. To prevent the ligature from exciting too great irritation and suppuration, the patient is always directed to attend the following day at the hospital, that a dresser may examine the seton, and remove it if the action be too great. Injection of iodine is a less satisfactory mode; but it is employed by Mr. Hill for the deeply seated ganglia of the ham, where the abscess that may follow the seton is extremely troublesome to heal. A ganglion now and then forms between the tibia and the inner hamstring, which Mr. Hill has found very tedious. In one case, the patient was obliged to relinquish his occupation through the pain which he felt in walking. His ganglion, being close to the knee-joint, was at first simply tapped and injected with iodine; but, as the fluid accumulated again, a thread was passed through, which was worn a week without much inconvenience; and the swelling gradually grew less, but did not disappear wholly, causing, not in ordinary walking, but when the limb was used to raise the body, as in going upstairs, a tolerably sharp pain. An attempt was then made to dislodge the hard nodule subcutaneously; this was so far accomplished that the tumour vanished, but some pain is still felt on going upstairs. The knee-joint was quite unaffected throughout these experiments. The ganglia that result from fluid collecting in the synovial sheath common to the tendons in the palm, and in that which lubricates the peronei behind the outer malleolus, Mr. Hill has tapped and injected with success, and without causing troublesome symptoms or stiffness afterwards. The application of pressure and blisters over these compound ganglia, in Mr. Hill's experience, is a waste of time, as these agents do not cause absorption of the fluid.

### GREAT NORTHERN HOSPITAL.

Mr. VINCENT has treated cases of ganglion in various ways, and with variable success. Forcible rupture by digital pressure, followed by continued pressure, and, if possible, a splint, have given the best results. Mr. Vincent considers the use of the latter advisable, to obtain the perfect cure of ganglion, as, in some cases of old standing, the ganglion, instead of being confined, as in recent cases, to the tissue between the tendon and the skin, extends around the tendon, and thus every movement of the tendon after the rupture prevents the adhesion of the walls of the sac; and hence the recurrence of the disease, and the necessity for the splint in cases where the patient can and will submit to its application. In private practice, the splint should always be insisted on. As hospital patients, however, refuse to discontinue their work, this plan is frequently impracticable.

[To be continued.]

### GUY'S HOSPITAL.

#### GANGLION IN CONJUNCTION WITH THE SEMI-MEMBRANOSUS TENDON: RECOVERY.

(Under the care of Mr. POLAND.)

WM. L., aged 17, was admitted with a tumour behind the inner hamstring tendon of the right knee. It was two inches in vertical direction, and an inch and a half across. It was very elastic, and gave a sensation of fluctuation. It could not be made to diminish in size, and did not seem to have any connexion with the knee-joint, although it seemed close upon it. He stated that it had been growing eighteen months; that he had never received any injury; that it had caused but little inconvenience or pain. He had used this leg more especially to set the lathe in motion, he being a brass finisher. A straight outside splint was applied, to keep the knee fixed, and boline ointment applied. In the course of a fortnight, the tumour not having diminished, it was

explored, when some gelatinous clear substance exuded, similar to what is found in ganglion at the back of the wrist. The tumour was then freely laid open, and the whole of the gelatinous contents completely emptied out. Pressure was then applied, and the knee kept perfectly stiff by the splint. The sac never refilled, and the patient left in all respects perfectly cured. The case was evidently one of ganglion in connexion with the insertion of the semimembranosus tendon.

### BRADFORD INFIRMARY.

#### CASE OF DIABETES MELLITUS UNDER MILK-TREATMENT: DEATH.

(Under the care of Dr. NICOL.)

FOR the following notes we are indebted to Mr. Roberts.

J. B., aged 15, living at Saltaire, was admitted under Dr. Nicol on May 30th, suffering from diabetes mellitus. He was small and ill-developed, but had enjoyed good health up to six months previously. At this time, he drank a great deal of water, and passed a considerable amount of urine. Some of his relations are phthisical. He attended a short time as an out-patient. On admission, the lad was put principally on meat-diet, with occasionally fish; and was ordered not to eat much bread and butter, or to have sugar in his tea. He also had the following draught three times a day: Tincture of sesquichloride of iron, 5 minims; spirit of chloroform, 10 minims; water, 1 ounce. A week afterwards, his feet and legs were noticed to be oedematous. The hepatic dulness was increased; and at the apex of the heart there was a distinct though faint systolic *bruit*. The lad gained in weight, but the amount of urine passed did not diminish.

On June 14th, the patient was ordered to have six pints of skimmed milk in the twenty-four hours; the mixture to be omitted, and nothing else but the milk taken. Three days afterwards, he complained of being hungry. The milk was increased to eight pints *per diem*. For the first three days of the skimmed milk treatment, the amount of urine passed considerably decreased; the oedema of the legs and feet disappeared; and the patient was apparently improving. On June 17th, his urine commenced gradually increasing, and continued so. He seemed reconciled to the milk, which was continued. On the morning of the 19th, at five o'clock, he was very restless, and complained of acute pain in the hypogastric region, with a frequent desire to go to stool, without any relief. A hot linseed-meal poultice gave much ease. At the morning visit (9.30), he was in a semi-comatose state, still able to answer a few questions. He had no pain; the pupils were dilated; pulse 156; respirations 32, deep and sighing; temperature 97.2. An enema of castor oil partly returned soon after introduction, without any fecal matter. He was able to swallow, and was given an ounce of wine-whey with three ounces of milk and water every two hours. He vomited occasionally until his death at 2 P.M. The urine this morning was acid, of specific gravity 1034. His motions throughout were clay-coloured.

POST MORTEM EXAMINATION, twenty-four hours after death.—The body was very thin; rigor mortis was present. The peritoneal cavity contained some fluid. The heart was soft; otherwise normal, except a little atheroma of the aortic semilunar valves and the neighbouring aorta. The lungs were passively congested, crepitant. The liver was enlarged, pale, hard, but friable, evidently fatty; the capsule was firmly adherent. The spleen was normal; the pancreas was normal; the stomach large. The small intestines were distended with gas, and for some inches in the ileum were very congested. Feces were present in the large intestine, from the sigmoid flexure downwards. The kidneys were very pale in the cortical portion (to all appearance fatty). The capsules were normal; a thick yellow fluid contained in them was found to be concentrated urine, with crystals of grape-sugar. On opening the skull-cavity, a good deal of fluid escaped from the arachnoid cavity. The visceral arachnoid and the pia mater were considerably congested; and the former was milky on the vessels, especially over the middle and anterior lobes. The brain was firm; the white matter was not so white as usual; puncta sanguinea were rather numerous; there was no fluid in the ventricles.

NOTE BY DR. NICOL.—The lad was in a very weak state from the first, just able to creep about, and much emaciated. No evidence could be got of his having resorted to the water-tap; nor did he have other food than the milk.

The amount of urine passed in twenty-four hours, ending 9 A.M., was as follows: on June 10th, 224 oz.; 11th, 228 oz.; 12th, 218 oz.; 13th, 224 oz.; 14th, 170 oz. (skimmed milk commenced); 15th, 165 oz.; 16th, 160 oz.; 17th, 181 oz.; 18th, 220 oz.; 19th, 280 oz. Specific gravity about 1030 at first and last; not taken constantly. The weight of the patient on May 23rd was 4 st. 5½ lbs.; June 1st, 4st. 6½ lbs.; 8th, 4 st. 7 lbs.; 14th, 4 st. 5½ lbs.

# THE GENERAL MEDICAL COUNCIL ON EDUCATION AND REGISTRATION.

SESSION, 1871.

Thursday, July 6th.

THE President, Dr. Paget, took the chair at 2 P.M.

*Professional Education.*—A draft report of the Committee on Professional Education was presented and ordered to be taken as read; and the Council proceeded to the discussion of certain resolutions founded thereon.

1. *Instruction in Pharmacy and Therapeutics.*—The resolution proposed on this subject was founded in the following sentences in the draft Report of the Committee.

"The separation of the teaching of pharmacy and therapeutics, the former being made an early and the latter a late course in the curriculum. The opinion of the Committee on Education, which included Dr. Christison and Dr. Aquilla Smith, and the views of all the best teachers of materia medica, were in favour of this separation. But some licensing bodies consider that therapeutics should not form the subject of a separate course of study, but should be considered an essential part of the courses on practical medicine and surgery. It must be admitted to be so, but still there is a necessity for special instruction, and without it, it may be confidently asserted that the progress in therapeutics will be slow. It seems desirable that a definite opinion should be come to on this point, and we propose to move a resolution to take the sense of the Council on this matter. So, also, it will be for consideration how far practical instruction in drugs and pharmaceutical preparations might not be substituted for formal lectures. For the last two sessions a plan of the kind has been carried on by Dr. Harvey at Aberdeen, and is said to have been highly successful."

Dr. PARKES said that, in dealing with the resolutions of which notice had been given, the Council would virtually dispose of the whole report except three or four paragraphs at the end, which referred to the mode of conducting professional examinations. The Council had great reason to be satisfied with the results of the influence which it had exercised. Almost all its recommendations to the examining boards had been attended to and adopted; and this was an answer to those who had spoken of the Council as wanting in influence. The first resolution which he had to propose was—

"That it is desirable that the instruction in Pharmacy should be separated from that in Therapeutics, and that the former should be obtained at an early, and the latter at a later, period of the professional curriculum."

It was scarcely necessary to enter into any argument in favour of separating the instruction in the elementary subject of pharmacy from that in therapeutics, which could only be understood after the study of physiology, medicine, and surgery. The Committee had collected the opinions of twelve teachers of materia medica. Of these, eight strongly recommended the separation; one was adverse; and three expressed no opinion, or did not give a decided one. Of these three, however, he had reason to believe that one was in favour of the separation; and the adverse opinion was expressed only in a modified form. In addition, there were in the Council itself two high authorities on the subject—Dr. Christison and Dr. Aquilla Smith; both these agreed that the proposed alteration was desirable; and at the end of the education report of 1869 there was appended a treatise by Dr. Christison in which the separation of the teaching of pharmacy from that of therapeutics was recommended. The Committee did not make any proposal as to the manner in which pharmacy should be taught, as the Council was adverse to giving opinions on matters of detail which would be better left to the discretion of the teaching and examining bodies. The report contained an allusion to Dr. Harvey's course of pharmacy at Aberdeen. No resolution regarding this was proposed, because it might be that it was only theoretically good; but he (Dr. Parkes) hoped that the plan would be made public. In Dr. Harvey's hands, the result had been that the students were taught the characters of drugs and the preparation of medicines in a more simple and agreeable manner than under the old system of causing them to acquire such knowledge in druggists' shops. They had been enabled to learn the subject in a thorough and satisfactory way.

Dr. CHRISTISON seconded the motion. He had taken great interest

in the subject—indeed, he believed he was the first to moot it. His experience as a teacher of materia medica for many years had shown him the defects of the present system. The Society of Apothecaries of London required materia medica to be studied in the first year. Now it was well known that therapeutics—which science was included in materia medica as commonly understood—could not be studied properly until the last year of professional education. It was argued by some, that in these days pharmacy might be entirely left to the druggists. If all medical men were prescribing physicians or surgeons only, this view would be admissible. But those who proposed it, forgot that country practitioners and those in the public services must of necessity practise pharmacy. In many parts, medicines could not be got from druggists; and there were many districts in which a druggist could not get a living. The study of pharmacy on the part of the intending practitioner of medicine might be restricted; but it could not be altogether dispensed with. It should be studied practically; a few lectures might be given, but the main part of the teaching should be practical. Dispensing could be very well taught by a competent dispenser in any medical school, provided sufficient accommodation were afforded. The period of the study of pharmacy should be very early; it should come after chemistry. As to therapeutics, it had been asked by some why the study should be distinct, and whether it would not form a part of the instruction in practice of medicine and surgery. It was no wonder that many had no faith in medicines, from the way in which therapeutics was taught. It was impossible to expect complete instruction in therapeutics to be included in a course of practice of medicine. They were beginning to devote their energy to the study of the action of medicine; and if the same energy were bestowed on this study as there had been on that of pathology and diagnosis during the last fifty years, there was no doubt that therapeutics would be advanced to a very high degree of perfection. Therapeutics formed one of the most important and most advanced of all the branches of the professional curriculum; and it should be one of the very last taught. The knowledge of pathology and diagnosis was of little value unless the remedies for the cure of disease and their action were also known.

Dr. MACROBIN considered that therapeutics should be taught after one systematic course of lectures on medicine, and before the commencement of hospital study. Dr. Harvey's success in teaching pharmacy was well known to him; he had ample accommodation, and was ably assisted by two pharmacists. He believed that a separate course of therapeutics was required.

Dr. HUMPHRY said that all proposed alterations must be looked on with care, especially when they tended to increase the already grievous burdens of students. He doubted whether it was expedient to come to a resolution which implied the establishment of a separate course of therapeutics. The information in the report was derived from teachers of materia medica; and it was known that every teacher held his own branch as of higher value than any others. Nothing could be more grievous to the student, or more likely to interfere with efficient examinations, than the addition of courses of lectures. He himself, while a student, had been obliged to neglect some courses in order to attend others. He agreed that the instruction in pharmacy should be practical; but demurred from the proposal to establish a separate course of therapeutics. The science, difficult as it was and founded on recondite physiological investigation, was at present in a scarcely sufficiently advanced state to form the subject of a special compulsory course. It had been said that the study of therapeutics in this way would promote science; but it must be remembered that the Council were not directly concerned with this, but had to see that students acquired a reasonable knowledge of science in its existing state. He proposed as an amendment—

"That practical instruction in pharmacy may with advantage be substituted for formal lectures on the subject, and should be attended at an early period of the medical curriculum; and that instruction in therapeutics should be conducted at a later period of the professional curriculum, either by a special course of lectures, or as an essential part of the courses of lectures on medicine and surgery."

Dr. ARJOHN seconded the amendment.

Dr. ANDREW WOOD said that if there were a branch of medicine in a more unsatisfactory condition than any other, it was therapeutics, both as regarded the state of the science and the manner of teaching it. It was very well to say that the Council ought not to increase the burdens of students; but the burdens of patients required also to be diminished. In the present system, materia medica was studied at a time when the proper understanding of therapeutics was impossible. Therapeutics formed the coping-stone of professional education, and should be taught at the end of the course or in the last summer. He believed that the establishment of a distinct course of therapeutics would give an impetus to the science.

Dr. STORRAR called Dr. Humphry's attention to the fact that the Council had avoided recommending courses of lectures; it spoke of instruction, no matter how obtained.

Dr. AQUILLA SMITH had, as a teacher of materia medica, been long convinced of the necessity of separating pharmacy from therapeutics. In Ireland, students attended the materia medica course in the first or second year; and he had found it an utter waste of time to attempt to teach therapeutics to first year's students, who had not even had time to acquire a knowledge of the characters of drugs. There was no occasion for increasing the courses of lectures; pharmacy could be taught by demonstration. Pharmacy was very imperfectly taught in Ireland; but there ought to be no difficulty in organising a course of instruction such as had been instituted by Dr. Harvey in Aberdeen. He spoke in favour of a separate course of therapeutics, to be attended towards the end of the curriculum.

Dr. APJOHN said that the plan proposed by Dr. Parkes would lead to an increase of the courses of lectures, and of the number of professors. Mr. HARGRAVE described the plan followed in the Royal College of Surgeons of Ireland by Dr. Macnamara, who gave two courses.

After a few remarks from Dr. Allen Thomson, Dr. Christison, Dr. Sharpey, Sir D. Corrigan, and Dr. Parkes, the amendment was put to the vote and lost. The original motion was carried, 15 voting in its favour.

2. *Instruction in Midwifery.*—The draft Report contained the following remarks on the subject.

"The length of time assigned to midwifery in most of the present curricula is too short, and the Committee on Education recommended that one entire winter session should be assigned to this subject, and that the amount of practical instruction should be increased. This opinion was shared by all the experienced teachers in midwifery, whose replies are given in the appendix to the Education Report of 1869. We, therefore, advise that the Council shall recommend that the systematic lectures on midwifery shall be given in the third or fourth winter course, and that the candidates shall be required to attend not less than twenty labours in addition to practical instruction in the diseases of women."

Dr. PARKES moved—

"That it is desirable that the course on midwifery should be extended, and that every candidate for a licence shall be required to attend not less than twenty labours."

The Committee did not wish to increase the labours of students. If this resolution were adopted, the Council would have to consider how to relieve the student in some other direction. Out of a number of experienced teachers of midwifery in London whose opinions had been taken, all with one or two exceptions agreed that it was not possible to do justice to the subject within the limited time allotted to it. The course of midwifery comprehended a portion of practice of medicine; it included the diseases of women and children. From the shortness of the time, however, the course was almost entirely confined to midwifery proper; and, the diseases of women and children not being treated of in the course of medicine, students got very little instruction in these important subjects. As to the number of labours attendance on which should be required, there was a variety of opinions; and the Committee had recommended the number which appeared to be required by most boards.

Mr. HARGRAVE seconded the motion.

Dr. HUMPHRY thought that the matter might be left to the examining bodies. He considered it unwise to require attendance on twenty labours. After the first few cases, the instruction obtained did not compensate for the time and trouble spent.

Dr. ALEXANDER WOOD objected to the motion. He thought that, if the Council overburdened students with lectures, other important sources of instruction would be neglected. He agreed with Dr. Humphry that attendance on more than a few labours was of little value to the student.

Dr. MACROBIN thought that ten cases were sufficient. It would be necessary to prolong the course to five months if it were to include the diseases of women and children. He proposed as an amendment—

"That it is desirable that instruction in Midwifery should be extended beyond three months, so as to embrace instruction in the Diseases of Women and Children, and that every candidate for a licence should be required to attend not less than ten cases of labour."

Dr. ANDREW WOOD seconded the amendment.

Dr. CHRISTISON said that courses of five months had long been given in some of the schools in Scotland.

Sir DOMINIC CORRIGAN would vote against both the motion and the amendment. The matter ought to be left entirely to the licensing bodies. The proposal would lead to a mere increase of the sale of certificates.

Dr. ANDREW WOOD did not think the remark as to the sale of certificates a fair one. He did not see how twenty cases of labour could be supplied to each student in Edinburgh; he thought that ten would be enough. No class of diseases formed so important a subject of study as those of women and children. It was impossible to include instruction in these subjects in a midwifery course of three months; and, under the present system, many students got no instruction in them.

Dr. STOKES said that the Council ought to endeavour to lighten the burdens of the student, and give him more time for self-instruction. Dr. Parkes's resolution went in a wrong direction. He would prefer to lessen the number of lectures and to increase the whole period of study.

Dr. RISDON BENNETT considered that the diseases of women and children ought not to be allocated to special professors. All that was peculiar in them could be taught in the ordinary courses of medicine and surgery and in the wards of hospitals. Accoucheurs, however, wished to absorb all operations on females, and all diseases connected with the female constitution, as well as those of children.

Dr. QUAIN agreed that the Council would be taking a wrong course in prescribing the length of a course of lectures. It was, at the same time, desirable that students should be better instructed in the diseases of women and children.

Dr. FLEMING thought that a three months' course was sufficient for midwifery proper. It would be difficult in all circumstances to supply twenty cases of labour.

Mr. QUAIN believed that resolutions passed with the object of extending courses of lectures were founded on a fallacy. It seemed as if the students of the present day were treated as if they were less zealous than those of former days. It was only in late years that attendance on lectures on midwifery was required; yet he remembered the time when the lectures on the course at University College were largely attended, though not demanded by the boards. No student in France or Germany was compelled to attend a course of lectures; yet large numbers did so. Again, there were now hospitals for diseases of children, and special wards for the same in the general hospitals; and these were frequented by students, although such attendance was not demanded by the boards. Diseases of women, also, were clinically studied in the hospitals under the teachers of midwifery.

After some remarks from Dr. Parkes, Dr. Macrobin's amendment was put to the vote and lost.

Dr. ANDREW WOOD moved as a further amendment, and Dr. MACROBIN seconded—

"That it is desirable that the instruction in midwifery should be extended, and that every candidate for a licence shall be required to attend not less than ten labours."

The amendment was negatived. The original motion was then put to the vote and was also lost.

3. *Pathological Anatomy.*—The next resolution was founded on the following remarks in the draft Report.

"The recommendation that Pathological Anatomy shall be made a separate course has not been carried out in all cases, but several of the licensing bodies have endeavoured to meet it by requiring a certificate of attendance and of practical instruction in the dead-house. We think that a certain number of systematic lectures should be added to this practical instruction."

Dr. PARKES proposed, and Dr. ANDREW WOOD seconded—

"That it is desirable that instruction in Pathological Anatomy should include a certain number of systematic lectures."

Dr. HUMPHRY objected to the addition of a course of lectures. He admitted, however, the importance of instruction in pathological anatomy, which was one of those subjects of which a knowledge must be obtained by the student in early life; while his knowledge of others, such as midwifery, could be gained afterwards. He remembered the great advantage which he had himself derived from the systematic teaching of pathology by Mr. Paget at St. Bartholomew's Hospital. He proposed as an amendment—

"That it is desirable that systematic instruction in Pathological Anatomy should form a part of professional education."

Dr. STOKES seconded the amendment.

Sir DOMINIC CORRIGAN said that pathological anatomy could not be taught separately from clinical medicine.

Dr. CHRISTISON preferred the amendment, as allowing most freedom. A chair of General Pathology had been instituted in the University of Edinburgh forty years ago. The first occupant—the late Dr. Thomson—and his successor Dr. Henderson, did not think that the terms of their appointment required them to teach pathological anatomy practically and minutely. Since the appointment of the present professor, Dr. Sanders, this difficulty had been got over; the subject was now taught both generally and in detail, and the lectures were among the most popular in Edinburgh. The fact that the students

took an interest in the subject, as they did in Edinburgh and as he understood them to do in London, was in itself a reason why the Council should make some such recommendation as was proposed.

Dr. ALLEN THOMSON said that his father, the first professor of general pathology in Edinburgh, was advanced in age at the time of his appointment, and was not able to avail himself fully of the means of practical instruction. Various circumstances, especially the introduction of the microscope, had produced since that time a great change in the study of pathological anatomy and had increased its popularity.

Dr. SHARPEY would support either of the proposals before the Council. Their object was to substitute systematic for desultory instruction. Pathological anatomy had been taught for many years in London. When he was appointed to University College, he found the late Sir Robert Carswell there as professor of pathological anatomy. The present professor in the College devoted two hours each week to special meetings for the demonstration of fresh pathological specimens.

Dr. GULL dissented from Sir D. Corrigan's remark that pathological anatomy could only be studied in dependence on clinical medicine. Morbid anatomy ought to be so taught as to enable the student to reason up from it to the clinical history of a case. The Council ought to express an opinion on the teaching of pathological anatomy.

The amendment was carried; and having been put as a substantive motion, was also carried.

4. *Class Examinations.*—The draft report of the Committee stated that "The Committee on Education strongly advised the enforcement of more regular Class Examinations. The Society of Apothecaries of London has ordered that all students shall produce evidence of having undergone these examinations; and we advise the Council to urge on all the licensing bodies to issue regulations requiring that written class examinations shall be frequent."

Dr. PARKES moved, and Dr. HUMPHRY seconded—

"That it is desirable that class-examinations should be compulsory, and that the Licensing Bodies should require them in all cases."

Sir DOMINIC CORRIGAN moved as an amendment, and Dr. AQUILLA SMITH seconded—

"That it is desirable that Class Examinations should form a part of every course of lectures, whether systematic or clinical." This amendment was lost.

Dr. ACLAND moved as an amendment, and Mr. QUAIN seconded—

"That it is desirable that Class Examinations should be compulsory on students." This amendment was also negatived.

A third amendment was then moved by Mr. QUAIN, and seconded by Dr. A. SMITH—

"That it is desirable that Class Examinations should form a necessary part of every course of instruction." This amendment was carried, and having been put as a substantive motion, was also carried.

Friday, July 7th.

*Conjoint Examinations.*—Dr. RISDON BENNETT made a statement in reference to arrangements for a Conjoint Examining Board for England, agreed to by a Conjoint Committee of the Royal Colleges of Physicians and Surgeons of England. He said that, before the introduction of the Medical Acts Amendment Bill by the Government in 1870, an endeavour had been made to form a conjoint examining board. When the Bill was introduced, the negotiations fell into abeyance; and were resumed when the Bill was withdrawn. The College of Physicians had taken great pains in the formation of a plan. Many schemes had been discussed and abandoned; sometimes on account of objections on the part of the Universities, but more generally through the difficulties raised by the Society of Apothecaries, who considered themselves precluded by their Act of Parliament from agreeing to proposals to which they might otherwise have been inclined to accede. A joint Committee of the Colleges of Physicians and Surgeons had at length framed a scheme, in such a way as to admit the co-operation of other examining boards. He believed that the Universities would concur in it. The scheme had not yet received the official sanction of the governing bodies of the two colleges; but there was no doubt that it would do so. It was proposed to appoint the Board of Examiners by means of a Committee of Reference, consisting of four members to be chosen by the College of Physicians, four by the College of Surgeons, and one by each of the Universities agreeing to the scheme. The difficulties in the way of forming conjoint boards were not insuperable; and their voluntary formation would probably modify the action of the Council in regard to medical legislation.

Mr. QUAIN expressed his general concurrence with Dr. Bennett's statement.

*Clinical Instruction.*—Dr. FLEMING proposed—

"That it is desirable that Clinical Instruction in Medicine and

Surgery should not be conducted so much by formal lectures in classrooms as appears from the evidence before the Council to be the case at present; but that hospital students should be divided into classes of limited numbers, so as to enable them individually to observe cases of disease, and to be examined upon them conversationally at the bedside or in proximity to it. Further, that it is desirable that, where possible, all students should serve as clinical assistants or dressers."

He said that much of the value of clinical instruction depended on the manner in which it was imparted. He was not satisfied with its present state; the immense advantages afforded by the large hospitals were not utilised as they ought to be. It was too much the fashion for students to merely go round the wards, and not be instructed in the particulars of cases, which were reserved for clinical lectures. Such lectures, as published in the periodicals, were usually very good treatises on some rare forms of disease; but they did not constitute clinical instruction in its proper sense. The College of Surgeons of England had to its credit taken steps in this matter; but the period required was too short. He read, in support of his view, extracts from the opinions furnished to the Council by Dr. Sieveking, Sir T. Watson, Mr. H. Labatt, Mr. Simon, Mr. Teale, etc. It was, he thought, an evil to require attendance on clinical medicine and on clinical surgery at the same time.

Dr. MACROBIN seconded the motion. In the Infirmary at Aberdeen, classes of limited number were assigned to the physicians and surgeons; and the students were not allowed to attend the medical and surgical cases at the same time.

Sir DOMINIC CORRIGAN considered that it would be quite impossible to carry out the plan proposed. Was it intended that students should be compelled to follow an incompetent teacher for three months? He objected to the compelling attendance on medicine and surgery at different times. If a rare case were admitted, all the students ought to have an opportunity of seeing it. The plan of limited classes would succeed only in small hospitals.

Dr. GULL proposed as an amendment—

"That the Council express their sense of the importance of making clinical instruction year by year more practical, and more consonant with the phenomena of disease, and less dependent upon formal clinical lectures."

It was not desirable to enter into details in the way proposed by Dr. Fleming. Clinical study must be made more practical; it should bear the same relation to the lectures on medicine and surgery that the work of the dissecting-room did to the course of anatomy.

Dr. STOKES seconded the amendment. He did not know any hospital in Dublin where formal clinical lectures had been delivered for many years. The physicians and surgeons usually lectured on the cases immediately on leaving the wards. To lecture on the cases in the wards would be cruel and barbarous. At the Meath Hospital, the practice was to give a short explanation of each case at the bedside, avoiding all painful topics; and to have a meeting after the visit, at which those students who had cases under their observation read their reports and were examined on them. He had found that only about one-fifth of the students attending really availed themselves of the special advantages offered; and he held that it was better to produce a small number of good and willing men than a large number of indifferent. Students could not be made diligent by law; and any attempt at coercion was quite beneath the Council.

Dr. CHRISTISON objected to minute details. During the last few years, there had been great improvement in clinical instruction; and all that was wanted was encouragement on the part of the Council. Clinical lectures were first instituted in Edinburgh in 1747; they consisted for a long time of mere reading of reports of cases, but in 1831 he (Dr. Christison) instituted clinical examinations. The students were often very desirous of a clinical lecture on a number of cases, as when an accumulation of instances of some one affection occurred; e.g., partial paralysis of the nerves of the face. His practice was to lecture on the cases and refer to their differences; and then to take the students to the wards and illustrate his remarks. He hoped that there would be no interference with the action of the medical authorities; but that at the same time it would be made known that the Council attached great importance to instruction at the bedside. He objected to lecturing to and examining students in the presence of the patients.

Dr. HUMPHRY advised that the Council should refrain from excessive interference, lest it should diminish the value of its opinion and its authority. Year by year there had been improvement in clinical instruction. He had personally visited the London hospitals to observe how the regulations of the College of Surgeons were carried out; and he found that clinical instruction was given in the large hospitals more perfectly than he had thought possible. It must be remembered, that this improvement in clinical teaching entailed great labour on the

medical staff of the hospitals. He thought it would be much the best plan for the Council to simply express its opinion of the importance of clinical instruction, and to leave its regulation in the hands of the examining bodies.

After some remarks from Mr. HARGRAVE, Dr. ANDREW WOOD, Dr. ALEXANDER WOOD, Dr. A. SMITH, Dr. QUAIN, Dr. PARKES, and the President, the amendment was put to the vote and lost; 7 voting for and 8 against it.

The original motion was then put to the vote and lost, three only voting for it.

*Chemistry.*—Dr. STORRAR moved—

"That it is desirable that students should have the option of acquiring an adequate knowledge of chemistry, and of passing an examination in it, before they enter upon the period recognised by the licensing bodies as the course of professional study."

The four years of professional study were at present overcrowded; and if the Council could lighten the burdens of the students and teachers, they should do so. In England, instruction in physical science was being introduced into the higher grammar schools, such as Eton, Marlborough, Clifton, etc. At the latter institution, the science-master had an annual salary of £300. He believed that youths of 17 would leave these schools with a good knowledge of chemistry. Besides, schools of science were springing up in many provincial towns; e.g., the College of Science at Newcastle-on-Tyne.

Mr. QUAIN seconded the motion. It was strange that chemistry was considered a medical science; it ought to be regarded as a part of general education. He was much pleased to see what was being done in the schools; for the ignorance in regard to physical science among men of high standing in the universities was lamentable. The Royal College of Surgeons of England allowed chemistry to be taken as part of the preliminary examination. He had inquired as to the effect of this regulation; and had found that, of 330 candidates at the last preliminary examination in general knowledge, 126 took chemistry, of whom 30 failed. It was not the duty of a medical body to examine in chemistry as such; but to ascertain whether the student understood its application to those branches of medicine in which a knowledge of it was required.

Dr. THOMSON agreed with the principle of the motion, but thought it should refer rather to the general principles of chemistry. He had been much impressed with the want of capacity in students for receiving scientific instruction; and he knew no better preparation than a preliminary education in chemistry and physics—to which he would even be disposed to add the elements of anatomy.

Dr. APJOHN said that it could not be possible to acquire any useful knowledge of chemistry in schools. He had no high opinion of the smattering acquired by boys. It would not be for the advantage of medicine that the limited knowledge of chemistry which they could obtain should be regarded as sufficient. He proposed as an amendment—

"That chemistry is a most important branch of medical education, and that the Council does not think it desirable to adopt any resolution which, if it had any practical effect, would tend to discourage the efficient study of the subject by medical students."

Dr. ANDREW WOOD seconded the amendment.

Dr. SHARPEY supported the original motion.

Dr. STORRAR intended that such an ordinary knowledge of chemistry should be required as was demanded of medical students. There were other parts of medical education in which it was necessary to keep up a knowledge of the science. He would avoid smattering, and anything like mere fireworks and explosions in schools; the instruction should be sound. Dr. Apjohn would be surprised to hear what was being done in some of the schools.

The amendment was lost, 8 voting for and 9 against it. The original motion was also lost, the votes being, for, 8; against, 11.

*Conjoint Examining Boards.*—Dr. PARKES proposed—

"That a letter be addressed to each licensing body transmitting a copy of the resolution of the Council of the 26th February, 1870, on the formation of conjoint examining boards, and urging that arrangements for the formation of such boards shall be undertaken without delay, and shall be communicated to the President of this Council before the close of the year."

Dr. STORRAR seconded the motion; which was opposed by Sir D. CORRIHAN, and supported by Dr. GULL and a number of other members.—Dr. HUMPHREY, Dr. APJOHN, and Dr. EMMERTON, expressed their belief that the Universities which they represented (Cambridge, Dublin, and Durham) would consent to take part in schemes of conjoint examination. In the absence of Dr. Acland, Dr. Humphrey believed that he might make the same statement regarding the University of Oxford.

The motion was then put to the vote, when 21 hands were held up

in its favour. Sir Dominic Corrigan declined to vote; and two members of the Council, Mr. Cooper and Dr. Acland, were absent.

The following is a copy of the resolution referred to in the motion.

"*Resolution of the 26th February, 1870.*—That this Council is of opinion that a joint examining board should be formed in each of the three divisions of the kingdom, and that every person who desires to be registered under any of the qualifications recognised in Schedule A to the Medical Act, shall be required, previously to such registration, to appear before one of these boards, and be examined on all the subjects which may be deemed advisable by the Medical Council; the rights and privileges of the Universities and Corporations being left, in all other respects, the same as at present."

Dr. PARKES moved, Dr. ANDREW WOOD seconded, and it was resolved—

"That the first resolution of the 28th February, 1870, be also transmitted to the licensing bodies at the same time as the previous resolution."

The following is a copy.

"*Resolution of 28th February, 1870.*—That, in accordance with the foregoing resolution, the Universities and Medical Corporations established in each division of the United Kingdom shall be requested to concert a scheme for the constitution and regulation of a conjoint examining board for that part of the kingdom to which they belong, and shall, on or before June 1st, 1870, transmit such scheme to the consideration of the General Medical Council."

Dr. ANDREW WOOD moved, Mr. HARGRAVE seconded, and it was agreed—

"That the Report of the Committee on Education be recommitted, and brought up to-morrow in a form adapted to the resolutions of the Council."

Saturday, July 8th.

*Removal of a Name from the Register.*—The Registrar was directed to erase from the Register the name of Frederick Henry Morris, of Swindon, Wilts, the Council being satisfied that he was the same person who was convicted at Devizes, on March 27th, 1871, of a misdemeanour, and of whose conviction a legal certificate had been submitted to the Council.

*Preliminary Examination.*—Dr. STORRAR moved, Dr. PARKES seconded, and it was resolved—"That the Report of the Committee on the application from the Board of Public Examiners of the Cape of Good Hope, be received and adopted." The report stated that the examinations corresponded generally with the matriculation examination at the University of London.

*Executive Committee.*—The Council having balloted for the Executive Committee, the following were found to be elected: Dr. Bennett; Dr. Acland; Dr. Sharpey; Dr. Quain; Dr. Andrew Wood; Dr. A. Smith.

*Proceedings under Penal Clauses of Medical Act.*—Mr. QUAIN raised a debate on this subject, stating that the promotion of the punishment of registered persons under Clauses XVIII and XXIX ought to be dealt with by the Council in its collective capacity, and that individual members ought not to be required to propose resolutions for carrying out the powers of the Council in such cases. He said that there ought not to be any pretext for the imputation of personal feeling.—Sir DOMINIC CORRIGAN did not think that any inconvenience had ever arisen from the plan usually followed by the Council.—Dr. GULL supported Mr. Quain's view. The procedure in case of punishment was thrown on individual members, whereas it was the duty of the Council as a whole.—After some further discussion in which Dr. Andrew Wood, Dr. Alexander Wood, Dr. Storrar, Dr. Risdon Bennett, Dr. A. Smith, and the President, took part—

Dr. BENNETT moved, Dr. A. THOMSON seconded, and it was resolved by a majority of 9 to 7—"That it be referred to the Executive Committee to report on the most desirable mode of procedure in the case of motions having reference to any penal measures."

*Report of the Finance Committee.*—Dr. SHARPEY, Treasurer, read the following report. The Finance Committee beg leave to present a statement of the income and expenditure of the year 1870, compared with the income and expenditure of the preceding year, also an estimate for 1871. It will be seen that there has been an increase of income in 1870, and that this is partly due to an increase in the number of registration fees; but it includes also the balance of the *Pharmacopœia* account and the proceeds of sales, making together £607:6, which, by direction of the Council, is now included in the ordinary income. The debt still owing to the Council on account of the *Pharmacopœia* was reduced in January last to £104:14. The expenditure of 1870 is less by £302:13:8 than that of 1869. The reduction is to a considerable extent due to a diminished charge for printing, especially for printed

reports of committees. It is expected that a considerable permanent saving under this head of expense will be effected by an arrangement that has been entered into for printing and binding the *Medical Register* at a reduced cost through the agency of Her Majesty's Stationary Office.

The table which accompanied the report showed that the income for the year 1870 amounted to £5,829:2:10, and the expenditure to £5,187:0:4; leaving a balance in favour of the Council of £642:2:6.

On the motion of Dr. SHARPEY, seconded by Dr. STORRAR, the report was received and adopted.

*The Office of Treasurer.*—Dr. SHARPEY having signified his desire to resign the office of Treasurer of the General Medical Council, which he had held during ten years, the PRESIDENT proposed, and it was assented to by acclamation—"That the hearty thanks of the Council be returned to Dr. Sharpey for his long and valuable services as Treasurer."

Dr. SMITH moved, Dr. PARKES seconded, and it was resolved—"That Dr. Bennett be elected Treasurer of the General Medical Council."

*The Returns from the Army and Indian Medical Boards.*—The Committee appointed on July 4th to consider and report on the returns from the Army and Indian Medical Boards, presented a report embodying communications which they recommended to be addressed to the Director-General of the Army Medical Department, and to the Military Secretary of the India Office, regarding the forms in which the returns were made. The modification proposed was that the returns should be made in the following form (taking, for example, the return from the Army Medical Board): "Total number of candidates, 57:—Succeeded in obtaining appointments, 36; Succeeded in examination, but not in obtaining appointments, there being only 36 vacancies, 17; Failed in examination, 4. Total, 57."

On the motion of Sir D. CORRIGAN, seconded by Dr. PARKES, the Report was received and adopted, and the letters drafted therein were ordered to be signed by the Registrar, and forwarded by him as directed.

*Report of the Pharmacopœia Committee.*—Dr. CHRISTISON read the following report.

"The Pharmacopœia Committee appointed by Minute of the Council, July 12, 1869, beg to report that, owing to the pressure of important business during the Sessions of the Council last year, no meeting of the Committee was held, and no Report was prepared for their consideration by Dr. Redwood. The Committee met on the 7th instant, and received a Report from Dr. Redwood, on the progress of Pharmacy since the date of his last Report. Some points of importance in connection with pharmaceutical preparations were discussed, and Dr. Redwood was requested to continue his services. It was also resolved that Dr. Christison, Dr. Quain, and Dr. Aquilla Smith be requested to continue their inquiries as regards additions or other changes in the *Pharmacopœia*, and that Dr. Redwood be requested, in addition to his duty of reporting on the progress of Pharmacy, to investigate, from time to time, the composition of articles in the *Pharmacopœia*, concerning which questions have been raised. As the sum of £75 remains as balance in the hands of the Committee, it will be unnecessary to ask the Council to place any further sum at the disposal of the Committee for use during the ensuing year."

After some discussion, it was resolved, on the motion of Dr. CHRISTISON, seconded by Dr. QUAIN, that the Report be received and adopted.

The Pharmacopœia Committee of last year, consisting of Dr. Christison, Dr. Quain, Dr. Sharpey, and Dr. A. Smith, was reappointed.

*Visitation of Examinations.*—Dr. ALEXANDER WOOD moved, Dr. HUMPHRY seconded, and it was resolved—

"That it is desirable that the visitation of the preliminary examinations and of those of the licensing boards be recommenced, and that a Committee be appointed to consider the best means of doing so." The Committee was appointed to consist of Dr. Alexander Wood, Chairman; Dr. Humphry; Dr. Thomson; Mr. Quain; Dr. A. Smith; Dr. Sharpey; Dr. Storrar.

Monday, July 10th.

*Report of the Committee on Professional Education.*—The draft report, as amended by the Committee, was brought up; and a large portion of the time of the meeting was spent in discussing it and making alterations. The discussion having been concluded,

Dr. PARKES moved, Dr. ANDREW WOOD seconded, and it was resolved—

"That the Report of the Committee on Professional Education, as now amended, be received and adopted, and that copies be sent to the several licensing bodies for their consideration."

Dr. RISDON BENNETT commented on the publication in medical journals of draft reports presented by Committees of the Council, before such reports had been duly considered and finally approved. He thought the proceeding undesirable; and suggested that the attention of the Business Committee should be directed to the subject.

*Conjoint Examining Boards.*—Dr. PARKES moved—

"That in case the arrangements for Conjoint Examining Boards are not completed in each division of the kingdom by the close of the year, in accordance with the recommendations of the Council on the subject, the Executive Committee shall be authorised to seek an interview with the Lord-President of the Privy Council, and to urge upon him the desirability of such medical legislation in the session of 1872 as may carry out the object the General Medical Council had in view, in passing the resolutions of the 26th and 28th February, 1870, and of the 7th July, 1871."

He said that the Council had sent to the licensing bodies its resolutions on the subject of forming conjoint examining boards; but he believed that this course thus taken would prove quite nugatory. Taking first England, the scheme agreed on by the joint Committee of the Colleges of Physicians and Surgeons seemed admirable; but difficulties still remained. The conjoint examining board ought to be perfect; but that which was proposed was not so, as it did not include the Apothecaries' Society, which would continue to grant its licence. The licentiates of the Society would still have the right to be registered; and the Society must either make arrangements with the College of Surgeons for a diploma in surgery, or with other licensing bodies. He had been glad to hear Dr. Christison's opinion that in Scotland there would be no insuperable objections on the part of the Universities to taking part in the formation of a conjoint examining board. In Ireland, he considered that a conjoint board could not be formed. After the close of the session of 1869, he had had much correspondence with the licensing bodies there; and had found that, while there was sometimes an apparent willingness to agree on a scheme, some of them would soon diverge greatly. He felt that there were unsurmountable difficulties with regard to Ireland; the principal of which was the opposing influence of Sir D. Corrigan. If the licensing bodies refused to amalgamate, the only plan remaining was to apply to Parliament for a bill to compel them to do so. He thought it would be the best plan to leave the matter at first in the hands of the Executive Committee, and to have a meeting of the Council to consider the bill after its introduction. The Council could not allow matters to go on from year to year as had been the case; if they did not carry out this duty, it would be done for them.

Dr. GULL seconded the motion.

Dr. ALEXANDER WOOD moved the previous question. He objected to any intimation of an intention to coerce the boards.

Dr. ANDREW WOOD supported Dr. Parkes's proposal. If the Council did not take the matter in hand, there were others who would. It was the duty of the Medical Council, if it deserved its name, to counsel the licensing bodies as to how they should act, so as to make the maintenance of their own rights conformable with the interests of the general public.

Mr. HARGRAVE said that he did not think that the formation of a conjoint board for Ireland was impossible.

Sir D. CORRIGAN opposed the resolution, which was supported by Dr. RISDON BENNETT.

Dr. STORRAR moved an amendment to the effect that the Council should meet early next year to receive reports as to the formation of conjoint examining boards, and to take such measures as might be necessary. This amendment was carried.

Some ordinary concluding formal business having been transacted, the session terminated.

*TESTIMONIAL TO A POOR-LAW MEDICAL OFFICER.*—On the 5th instant, a testimonial was presented to Mr. Richard Ley, surgeon, late of South Molton, Devon, by the parishioners of Chittlehampton, Warkleigh, and Salterleigh, of which places he had for many years been medical officer. The testimonial, which was presented by the Rev. R. E. Trefusis, vicar of Chittlehampton, in the names of the donors, consisted of a handsome tea-service, with a dozen dessert knives and forks. The vicar, in presenting the testimonial, alluded to Mr. Ley's valuable services in attending to the sanitary state of the parish, especially during an epidemic of typhoid fever which prevailed in the district last year.

## THERAPEUTIC RECORD.

**PREVENTIVE TREATMENT OF LEAD-POISONING.**—M. Péligré, director of one of the principal glass manufactories in France, noticed some time ago that two of his workmen, who were in the habit of drinking a quantity of milk daily, were quite free from symptoms of lead-poisoning, from which the other persons employed suffered extensively. He consequently caused each of his workpeople to bring to the manufactory a quart of milk daily; and from the time when this mode of diet was commenced, there has not been a single case of lead-colic. Dr. Méhu recommends, as a means of removing the fine lead-particles from the skin, the use of baths of hydrochlorate of soda. A solution is prepared by mixing 400 grammes (about 13 ounces) of dry chloride of lime, 800 grammes of crystallised carbonate of soda, and 10 litres of water. This is sufficient for a bath of 44 gallons. The person remains in the bath about half an hour, and rubs with his hand or with a brush the parts where the lead has been deposited.—*Journal de Méd. et de Chirurgie Pratiques*, Mars 1871.

**CARBOLIC ACID IN SNAKE-BITE.**—Dr. Weir Mitchell, from observations on the bite of the rattlesnake, and MM. Gicquian and Viaud Grand-Maraîs, from observations on that of the viper, have arrived at the conclusion that the application of carbolic acid immediately on the receipt of the injury prevents both local and general poisoning. The pure acid, however, if applied in too great quantity, is liable to produce sloughing, and even dangerous symptoms: hence it is best used in the proportion of two parts of acid and one of alcohol. Given internally, or applied to the wound at a late period, it produces no effect. It is believed to act, not by neutralising the poison, but by causing contraction of the small vessels, and thus preventing its absorption.—*Journal de Méd. de l'Ouest*, and *Bull. Génér. de Thér.*, March 30, 1871.

**AN ANTIPARASITIC OINTMENT.**—*Lo Sperimentale* for June quotes from *L'Igea* the following formula, which is said to be useful in itch, favus, and other parasitic skin-diseases: Sublimed sulphur, 9 grammes; ammonio-chloride of mercury, 75 centigrammes; sulphide of mercury, 75 centigrammes; olive-oil, 6 grammes; fresh lard, 24 grammes; creasote, 2 grammes.

**THE INDUCED GALVANIC CURRENT IN ILEUS.**—Dr. Macario relates in the *Annario delle Scienze Mediche* for 1870 the case of a man aged 70, who had long been subject to obstinate constipation, and who was suddenly seized with severe pain in the umbilical region, violent cramps, and abundant vomiting, first of bilious, and then of stercoraceous matters. He was in a state of semi-stupor, with small weak pulse and singultus. One pole of a Gaiffe's induction-apparatus was introduced into the rectum, and the other was applied by means of a wet sponge to the abdominal wall over the transverse colon. Energetic contractions of the abdominal muscles were produced, and were attended with much pain; but, at the end of ten minutes, the pain and vomiting had ceased. Four hours afterwards, the patient had a spontaneous evacuation of the bowels, followed by two others in the course of the night; and the next day he was convalescent.

**SULPHOCARBOLATE OF ZINC IN OTORRHOEA.**—At a recent congress of German surgeons in Prague, Dr. Zaufal said that he had used solution of the sulphocarbolate of zinc in fourteen cases of otorrhea, with satisfactory results. The strength of the solution was one or two grains to the ounce.

**SPASMODIC CONTRACTIONS OF A FRACTURED LIMB: ARTERIAL COMPRESSION.**—M. Broca had under his care a few months ago, in the Hôpital de la Pitié, a man who had broken both bones of the leg an hour before his admission to the hospital. The muscular contraction was so violent that it was impossible to reduce the fracture. M. Broca thereon employed a method which he had found successful in several cases of painful cramps of the lower limb—viz., compression of the femoral artery. Almost immediately the muscles became relaxed, and reduction was effected with ease. Subsequently, in reapplying the splints, the contraction returned, and was again overcome by the same means. The *Journal de Médecine et de Chirurgie Pratiques* for March, in relating the case, says that the simple and easy means employed by M. Broca ought always to have a trial before giving chloroform, which is often done in such cases.

THE Subscriptions to the Association for the year 1871 became due in advance on January 1st. All which are not already paid, should be forwarded to the General Secretary, Mr. T. Watkin Williams, 13, New Hall Street, Birmingham; or to the Secretaries of Branches.

## BRITISH MEDICAL JOURNAL.

SATURDAY, JULY 15TH, 1871.

### MEDICAL LEGISLATION.

DR. DALRYMPLE has been favourably known since he entered the House of Commons by a clear, intelligent, and earnest advocacy of some measures for affording relief to an acknowledged, pressing, but as yet untouched evil. The irresistible passion for alcoholic drinks becomes, under some circumstances, a mental malady. Ferocious, not to be resisted by its victims, it works misery, ruin, and destruction so frequently and painfully, that a measure for the restraint of such persons has been favourably considered in principle by men of all opinions. The inherent difficulties of any measure for the purpose have probably alone deterred legislators from dealing with it before now. Combining technical professional skill with the legislative position, Dr. Dalrymple courageously attacked the difficulties which have daunted those who came before him in their consideration. He has succeeded in combining the support of divers and powerful sections of society. The opinions of the medical profession have been with him from the first. The medical faculties of more than one Scottish University were among his early supporters. The Parliamentary Bills Committee of the British Medical Association, after hearing a personal explanation from Dr. Dalrymple of the character of his Bill, pledged itself to support the measure; and, at the recent deputation to the Home Secretary, representatives of bodies as widely differing as the Licensed Victuallers' Association and the Licensing Amendment Association combined to favour the Bill. Our own Association was prepared to take energetic parliamentary action to assist in securing a full hearing for a measure bearing so largely on public interests, and so desirable in many ways, but that, at the interview with Mr. Bruce, an arrangement was arrived at that, after taking a debate on the second reading, with a view to the adequate discussion of the subject, a Select Committee of the House should be granted to investigate the results of the experience in other countries, and to take evidence of the working of such voluntary institutions as exist here and elsewhere for the treatment of habitual drunkards. Dr. Dalrymple explained the machinery of his Bill, and defended its provisions with great clearness and force. The Bill adopted the machinery of the lunacy laws, which he would have avoided if he could, but thought it a lesser evil to avail himself of this machinery than to create new machinery. Moreover, his contention was, that an habitual drunkard was *ipso facto non compos mentis*. He was told that the Commissioners in Lunacy objected to the Bill; and he was not surprised, because the *genus* Commissioner, like everybody else, did not like increased work without increased pay. But he thought that the work imposed on them by the Bill would be comparatively small, unless, indeed the Bill succeeded beyond his expectations, and then its success would be its own justification. There were three modes in which the habitual drunkard might be placed under restraint—by voluntary action, which had nearly failed through inability to keep the person sufficiently long in restraint; by the action of relatives; and by magisterial action in committing to these reformatory persons who had been three times committed within six months either for drunkenness or for offences committed under the influence of drunkenness. The chief objection to the Bill was its infringement on personal liberty. People were supposed to have an inherent and indefensible right to get drunk as they liked; but he maintained that when, through the abuse of alcoholic liquor, a man became dangerous to himself and to others and ruinous to

his family, making them burdens on society, and leading them into poverty, disease, and crime, personal liberty must succumb to public exigencies; and this principle was constantly acted upon. Then it was said that the power given to relatives would, for interested and sordid motives, be abused. He did not deny that persons had been unjustly detained as lunatics, though such cases were far less frequent than they were supposed to be; but the Bill provided against such an abuse of it, and he hoped effectually. He conceived that a man proved to be in the habit of endangering his own life and the lives of others, and ruining his family, from his indulgence in drink, might fairly come under the operation of the Bill. There was no chance of an undue infringement of personal liberty; because, to bring about such a result, there must be a combination of unscrupulous relatives, reformatory proprietors ready to incur the penalties imposed by the Act of the 8th and 9th Victoria, two corrupt medical men to sign certificates, blind magistrates, hoodwinked inspectors, and patients who could not talk and give any explanation of their own condition.

Under one of the provisions of the Bill no person admitted to a reformatory on his own application, or on the application of his friends, should be detained for less than three months, or more than twelve months; but power would be given to proper authorities to extend or shorten the period of detention. He had been told that it would be matter of immense difficulty to define an "habitual drunkard," but he maintained that a sufficient definition was given in the first part of the Bill, where an habitual drunkard was described as a person who, by reason of frequent, excessive, or constant use of intoxicating liquors, was incapable of self-control, was dangerous to himself or others, or incapable of taking care of himself and family. The Home Secretary, who had stated that a generation ago a distinguished statesman and an eminent poet would, under the present Bill, have been shut up in a reformatory as habitual drunkards, could not have given sufficient attention to that definition, because it was evident that men who obtained such a high character and position could not have drunk to such an excess as to render themselves incapable of managing their affairs. With regard to the objection raised against the Bill on account of the cost it would entail, he might put against that expenditure the present cost of criminals, and show that the measure, in preventing crime, would result in economy to ratepayers; and it was to be observed that in certain reformatories for the inebriated, established in the United States, 40 or 60 per cent. were cured. Under these circumstances, he proposed that power should be given to magistrates and Boards of Guardians to establish and maintain reformatories under the Bill, and there was no need to fear that those functionaries would rush recklessly and unnecessarily into expense. In his opinion, the first effect of the Bill would be to cause these reformatories to be established for the upper and middle classes. Their working would then be watched, and if they proved successful, their success would justify magistrates and guardians in providing similar institutions for the poorer classes. He admitted that relapses into drunkenness were at present frequent; but he contended that, if there should be 75 per cent. of failures in the first year of such a system as he recommended, there would only be 50 per cent. in the next year, fewer in the year after, and so on until they came down to a residuum beyond which they could not hope to go, for there would be some irrecoverable drunkards just as there were some irrecoverable lunatics. He was told that the measure partook too much of the parental character; but the system which he advocated existed in America, and he asked whether there was any country in the world where self-government was more carried out than in America.

## SPIRITUALISM TESTED.

### I.

"SPIRITUALISM is a religion. As such, it is held tenaciously and honestly by many well-meaning people. To reason with these would be a waste of words, just as much as would be the attempt to persuade a madman out of his delusion. But there are some who halt between

belief and unbelief, for the reason mainly that they have no clear conception of what knowledge is, and of how things are to be proved."

It is for the benefit of the latter class that several eminent physiologists and psychologists, and pre-eminently Dr. Hammond of New York (the Professor of Diseases of the Mind and Nervous System in the Bellevue Hospital College, and the Editor of the *Journal of Psychological Medicine*), from whom we have borrowed the above quotation, have taken the trouble to show in a popular manner that all the wondrous so-called facts of spiritualism may be accounted for without any appeal to unknown powers. As any of our medical brethren may be unexpectedly called upon to argue a weak-minded patient out of the follies of spiritualism, we may possibly be doing a good service to those who have little leisure for psychological study, if we briefly touch upon some of the points which forcibly tell against the present popular delusion, and which show how its most startling facts can be rationally explained. Many of the phenomena that are passed off upon an excited party of willing believers, as spiritualistic manifestations, are simply clever acts of sleight-of-hand; and the perfection to which this art is carried by accomplished performers is almost incredible.

The learned American physician to whom we have already referred invited several medical and other friends to witness, in his own library some surprising spiritualistic exhibitions by a first-class "medium". The operator went through all the performances of the celebrated Davenport brothers, who a few years ago created a great sensation in London. He was securely tied by an old naval officer, who exhausted his strength and ingenuity in devising bands and knots which, he felt assured, would render any movement of the limbs impossible. A screen was then placed in front of the "medium", and in an instant an accordion was played, a bell rung, and a tambourine struck. The performer then requested that the screen might be removed; and, on this being done, he was found to be tied in precisely the same way as when the officer finished his task, not a cord or knot having been interfered with. In a second experiment he was tied with, if possible, additional care, and yet the instant he was concealed he rang a bell. Moreover, the "rappings" of this gentleman—a Dr. von Vleck, who is devoting his time and talents to the exposure of the impositions of the spiritualists—were perfect; and he read communications from the dead, made on folded slips of paper, with fully as much skill as if he had truly been a professional medium. Even after he had fully explained to the spectators the manner in which he accomplished his marvellous performances, it was difficult to make some of them believe that they had not witnessed something supernatural.

Many of our readers are doubtless aware that one of the most remarkable phenomena of spiritualism is the facility of rising in the air in opposition to the force of gravity. This property is claimed not only for inanimate objects, as tables, chairs, etc., but also for the human body. Some years ago, a well-known literary man of undoubted credibility—the late Mr. Bell—described in the *Cornhill Magazine* the sights that he saw, or believed that he saw, at a spiritualistic *séance*; and in this chapter of wonders he declared that he saw Mr. Home floating for some minutes near the ceiling of a partly darkened room. (Unfortunately, however, for the cause of spiritualism, he did not succeed in rising in the air during his late visit to St. Petersburg, when a distinguished Russian professor was present by invitation to witness the ascent.) Only a few weeks ago a writer in *Once a Week* declared that some years ago, when at Baltimore, he saw an electro-biologist raise a man larger and heavier than himself six inches in the air, where he remained suspended for some seconds; and we have no reason to doubt his good faith, although we may question his powers of observation. Long before the present spiritualistic era cases are recorded in which persons have been raised from the ground without the aid of material agencies. Philostratus, who lived in the latter part of the second century, states in his *Life of Apollonius of Tyana*, who flourished about a hundred years earlier, that this philosopher saw the Bramins of India rise in the air to the height of two cubits and walk there without earthly support. The Indian jugglers of all ages have been celebrated for their feats of legerdemain; and not

many years ago, a Colonel Stodare, who had resided in the East, and had learnt the mysterious trick, when exhibiting his powers in the Egyptian Hall, caused a woman to remain suspended in the air after a table, on which she had been reclining, was removed. Long wands were passed through the air above and below her, without any support being detected, except a small cane which she openly held in her hand and which rested lightly on the floor.

Dr. Hammond, who has carefully investigated all the recorded cases of "levitation", shows in an unquestionable manner that all of them may be explained by a reference to one or other of the following causes: 1. An hallucination on the part of the subject or of those asserting themselves to be witnesses; 2. Unintentional exaggeration, misinterpretation, or an inaccuracy of statement; 3. Insufficient evidence (to which most cases must be referred); 4. Intentional misstatement; and 5. Legerdemain, which is sufficient to account for cases that have had any kind of real existence.

On the whole, there are about fifty cases of levitation on record, a large proportion of them occurring amongst the saints of the Roman Catholic Church. Far rarer are the cases of an opposite kind, in which the force of gravity is so increased as to prevent the affected person from rising. Dr. Hammond, when he was writing his interesting and valuable little book on *The Physics and Physiology of Spiritualism*, had under his care "a lady who declares that she cannot rise from her chair, and who has convinced several friends that she speaks the truth", although in reality she has the free use of her limbs; and he tells us the following amusing story of a still more remarkable case that occurred in the olden times.

"In the northern borders of England, and on the other side of the Humber, in the parish of Hoveden, lived the rector of that church with his concubine. This concubine one day sat rather imprudently on the tomb of St. Osanna, sister to King Ofred, which was made of wood and raised above the ground in the shape of a seat. When she attempted to rise from the place her posteriors stuck to the wood, in such a manner that she could never be parted from it, till, in the presence of the people who ran to see her, she had suffered her clothes to be torn from her, and had received a severe discipline on her naked body, and that to a great effusion of blood, and with many tears and devout supplications on her part; which done, and after she had engaged to submit to further penitence, she was divinely released."

A remedy so potent in gravitation, says Dr. Hammond, would probably prove equally efficacious in levitation, and we heartily concur with him.

We shall resume and conclude this subject in an early number, when we shall show that many so-called spiritualistic manifestations are simply due to a particular nervous temperament, and to certain forms of disease which have been long recognised and are thoroughly understood by the medical profession.

### THE NEW PUBLIC HEALTH AND RELIEF DEPARTMENT.

THE Bill, often promised and long desired, for consolidating the Health Department of the Government, has at last been drawn. It was read for the first time on the 6th instant, and is now in print. As this is a matter of great medical as well as public interest, we give a *resumé* of the principal clauses of the Bill. The Act may be cited as "The Local Government Board Act, 1871."

Clause (1) enacts that a Board shall be established to be called "The Local Government Board"; and that on its establishment the Poor Law Board shall cease to exist, all its powers relating to the relief of the poor, as also of the Secretary of State relating to the registration of births, deaths, and marriages, to public health and sanitary matters (including local government, drainage-works, baths and washhouses, town and public improvements, artisans' and labourers' dwellings), local taxation returns, etc., and of the Privy Council for the prevention of disease, the ensuring of the performance of vaccination, and other powers for protecting the public health, being transferred to the new Board.

Clause III enacts that the Local Government Board shall consist of a President, to be appointed by the Crown, and of the Lord-President of the Privy Council, all the principal Secretaries of State, the Lord Privy Seal, and the Chancellor of the Exchequer. The Clause further enacts that the Board shall become established so soon as the first President is appointed; it also provides for the official staff.

Clause VI provides for the transfer to the authority of the Local Government Board of the official staff of the several departments which are to become consolidated into the Local Government Board.

Clause VII (the last) provides for the validity of all documents and contracts passed or entered into under the several powers possessed respectively by the departments which are to be consolidated into the one department of the Local Government Board; and directs that the title "Local Government Board" shall be deemed to be substituted where necessary for any title in any documents where a different title is expressed under Acts now in force.

We will defer until next week our remarks on this Bill.

THE annual dinner of the Middlesex Hospital Club will take place at Willis's Rooms on Friday, G. H. Makins, Esq., in the chair.

THE health of Paris is good; the death-rate continues sensibly to diminish, 872 deaths only having occurred this week against 1106 in the preceding one.

A RUSSIAN lady, Marie Bokowa, of St. Petersburg, has just graduated with distinction at Zurich in medicine, surgery, and obstetrics. This lady rendered valuable services in the War Hospital at Hericourt.

MR. ARTHUR KEMPE has resigned the office of surgeon to the Devon and Exeter Hospital; and, at a special Court of the Governors held on June 30th, was appointed consulting surgeon and honorary governor. On the same occasion, Mr. Wilson Caird was, by a majority of votes, elected surgeon to the hospital.

DR. MINTER, of the royal yacht, has been nominated to succeed Deputy-Inspector of Hospitals and Fleets W. T. Domville at Malta Hospital. We (*Army and Navy Gazette*) understand that Dr. Minter's appointment has been made at the request of the Court, and that the authorities now in office could not reasonably refuse to comply with a wish of the kind.

### HONOURS TO MEDICAL MEN.

THE order of the Iron Crown of the second class has been conferred on Dr. Frerichs of Berlin. M. Ricord and M. Demarquay have been promoted to the grades of Grand Officer and Commander respectively of the Legion of Honour, for their services during the siege of Paris.

### THE LATE DR. JOHN HATTON.

AT a meeting on Thursday last of the Royal National Life Boat Institution, a contribution of £700 was received from Mrs. Jane Hatton, to defray the cost of the Dungeness new Life Boat Station, in memory of her late husband, Dr. Hatton, F.R.C.S., of Belvedere, Kent, who died a few months ago.

### INTERNATIONAL COURTESIES.

THE Count Flavigny and Drs. Ricord and Demarquay have arrived in London, representing the French Government and the French International Aid Society. They are the bearers of thanks and honourable recognition of the friendly assistance rendered to the sick and wounded of the French army by the officers of the British Society under the presidency of Colonel Loyd Lindsay. Colonel Lindsay entertains all the principal members of the staff of the society who served during the war at a banquet at Greenwich on Saturday. The French delegates will be present. They have brought with them four ambulance-waggons, fully equipped, after the new model, as presents to the British Society. These have been taken to Wimbledon, where they are now being shown.

## SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

OUR Leeds correspondent writes :—"A soirée in connection with the Sheffield Medico-Chirurgical Society was held at the Infirmary on June 28th. Mr. Barber, the President, in an eloquent address, directed the attention of the profession to the importance of such gatherings, and said that, owing in part to the introduction of 'new blood' in the town, he had no doubt that Sheffield would soon take a high scientific position. Among many objects of interest exhibited was the melanometer, an instrument for detecting the exact amount of pigment in urine, invented by Dr. Frank-Smith."

## THE CONJOINT BOARD.

THERE will be a meeting of the Committees of the Royal Colleges of Physicians and Surgeons on the Conjoint Board this (Friday) evening, at half-past eight, at the College of Physicians. Mr. Edward Cock, not having been re-elected on the Council of the College of Surgeons, ceases to be a member of the Committee.

## MANCHESTER ROYAL INFIRMARY.

By the death of Mr. Dumville, Mr. Bowring becomes full Surgeon to the Manchester Royal Infirmary. This appointment leaves no vacancy, however, as the Board decided some years ago not to elect any more dispensary surgeons until those already on the staff had succeeded to the post of full surgeon in due rotation. Mr. Bowring being the last dispensary surgeon on the list, the next death or resignation will, of course, leave a vacancy. The last election took place in 1854, when Mr. Bowring was appointed dispensary surgeon.

## THE MEDICAL ARRANGEMENTS AT THE WIMBLEDON CAMP.

THE medical arrangements are in every respect the same as last year. Surgeon-Major Wyatt, Coldstream Guards, is the surgeon in charge, while Assistant-Surgeon Temple, V.C., Royal Artillery, and Dr. Mayo, Assistant-Surgeon Inns of Court Volunteers, are the assistant-surgeons in charge of the troops and volunteers respectively. Dr. Mayo has just returned decorated from Darmstadt, where he has had medical charge of one of the National Aid Society's ambulances. With the exception of an inordinate amount of rheumatism, which is quite intelligible, the health of the camp has been pretty good.

## ST. ANDREW'S MEDICAL GRADUATES' ASSOCIATION.

THE summer session of this Association was held at Maidenhead on Friday, July 7th; the President of the Association, Dr. Day of Stafford, in the chair. This Association, with much practical wisdom and no little zeal, devotes its summer session to the "cultivation of social intercourse and good fellowship", leaving "the advancement of the science and art of medicine" for its winter work. With "Skindle's" well known hotel for head-quarters and commissariat centre, creature-comforts were well provided for; and the brilliant sunny day lent an additional charm to the glorious Thames, the lovely Cliveden woods, the stately house of Hedsor (which, by the great kindness of Lord Boston, was visited), and the wonderful pines of Dropmore. The holiday was a success and a pleasure, too infrequent in a busy doctor's life. Not the least welcome guest was M. Jules Sarazin, the Surgeon-in-chief of the late Hundred Guards of the Emperor of the French.

## THE SANITARY CONDITION OF LIVERPOOL.

DRS. PARKES and SANDERSON, appointed some time ago to conduct investigations with regard to the sanitary condition of Liverpool, have forwarded to the local corporation a first instalment of their report. A prominent part of their duties was to inquire into the influence of cinder refuse deposits, containing in a greater or less degree animal and vegetable matter, on the health of persons inhabiting houses built upon it. On this point, they say "the refuse has only lately been used; and as it certainly does not produce any one special disease, it would be impossible without very prolonged and careful comparison of the health of those living on it, and of classes of the same rank and occupation living on other soils, to give an opinion. There could be no doubt, however,

that from a soil formed of such refuse and gradually decomposing, some effluvia must be given out, which would be likely to pass into houses placed on the soil, and, on the general principle of requiring purity of air, such a soil is objectionable—at any rate when first laid down." They therefore make the following recommendations :—"That no excavation should be used for the reception of cinder refuse unless it is sufficiently drained; that the cinder refuse-soil should not be built upon for at least two years from the date of the last deposit; that inquiry should be made as to the practicability of getting rid of road scrapings without mixing them with cinder refuse; and that much greater care than is exercised at present should be taken by the Health Committee officials in the selection of material deposited. With respect to building upon old deposits of chemical refuse, Drs. Parkes and Sanderson do not think that health must, of necessity, be injuriously affected by the practice of itself; but they found in one district examined sulphuretted hydrogen gas evolved from products of chemical manufactories passed into houses from the sewers. To obviate this, it would seem to be necessary to prohibit the passing of acid liquids into the sewers. A considerable portion of the report relates to the condition of the sewers. The recommendations of the Commissioners on this subject are thus summed up :—"1. We recommend that a complete and exhaustive inquiry be made as to the existence of deposits in the sewers, and that in all cases in which such deposits are, in the opinion of the borough engineer, dependent on defective construction, defective inclination, or insufficient supply of water, the works necessary for the remedy of these defects be immediately commenced. 2. In those cases in which the foul condition of the sewers appears to be unavoidable—*e.g.*, in those sewers which are affected by the tide—we recommend ventilation. For this purpose, we think that spacious and lofty shafts afford the only effective means. 3. We do not recommend the adoption of any general system of ventilation, entirely agreeing with your borough engineer in the opinion that for well-constructed sewers of good inclination, with sufficient supply of water, it is unnecessary. 4. We recommend that a complete report be made as to the quantity of waste water discharged into the sewers by manufacturers, with a view, first, to the prevention of its introduction into the sewers in a warm state; and, second, to its being, if possible, utilised for surface cleaning and sewer flushing."

## ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

By order of the Council, the library (on account of the alterations in progress connected with the meeting room) will be closed during the months of August and September—closing on Saturday, July 29th, and re-opening on Monday, October 2nd. No books can be taken out of the library during the above period; but those in the possession of Fellows at the time of the closing may be retained till the re-opening of the library. The front room will remain open as a reading-room for periodicals till August 12th, as usual.

## SEVENTEEN CHILDREN POISONED.

ON Friday in Liverpool no fewer than seventeen children were poisoned by eating Calabar beans, which they had picked up on some vacant land. Medical aid was at once invoked, and before evening set in they were pronounced out of danger. The corporation carts in three loads removed the whole of the rubbish to a pit where the beans were properly covered with clay. It is supposed that the beans were brought from the docks, but from what ship or dock has not yet transpired.

## DR. MEADOWS'S CASE OF NEPHROTOMY.

THIS case, which we noticed last week, unfortunately proved fatal on the sixth day from hæmorrhage, which took place from the pedicle, which was secured by a ligature, and not a clamp, as we stated by mistake. There was no pedicle that would admit the application of the clamp; for the mass was separated close to the spine, and the ligature was applied within an inch of the vena cava. There was not the slightest trace of inflammation anywhere. The gradual and ultimately complete destruction of the secreting substance of the kidney no doubt

led to complementary enlargement of the healthy organ on the opposite side, and diminished to a minimum the chances of uræmic symptoms supervening after the operation; but such would likely be the condition in the majority of cases in which it might be advisable to perform the operation of nephrotomy. The cause of death appears to have been purely accidental, and altogether the case lends support to the view that the operation is not so intrinsically formidable as has been generally supposed.

#### NEW FELLOWS.

At a meeting of the Council of the Royal College of Surgeons on Thursday last, the following members of the College, having been elected Fellows at a previous meeting, were admitted as such, viz.: Messrs. John Morgan Puddicombe, L.S.A., coroner for the borough of Dartmouth, Devon, diploma of membership dated March 31, 1837; and Edward Glover Bartlam, L.S.A., coroner for the borough of Wenlock, of Broseley, Salop, October 25, 1839.

#### CHOLERA IN ST. PETERSBURG.

THE following are further particulars of the mortality from cholera in St. Petersburg, so far as the bulletins which have appeared from time to time in the St. Petersburg papers record the progress of the epidemic.

	CASES.	DEATHS.
On June 3.....	21.....	8
" 4.....	7.....	7
" 7.....	15.....	7
" 8.....	16.....	7
" 9.....	28.....	11
" 10.....	21.....	5
" 11.....	23.....	12
" 12.....	27.....	13
" 13.....	33.....	13

The total numbers since the commencement of the epidemic (August 17th, 1870) to June 14th, 1871, are as follows:

	CASES.	RECOVERIES.	DEATHS.
Male .....	3,236.....	1,724.....	1,353
Female .....	1,654.....	939.....	615
TOTAL.....	4,890.....	2,663.....	1,968

#### POOR-LAW MEDICAL OFFICERS' ASSOCIATION.

THE annual assemblage of this Association will be held in the Freemasons' Tavern, Great Queen Street, Lincoln's Inn Fields, on Wednesday, July 26th, at half-past 4 P.M. precisely, when, as we understand, several subjects of much importance to the service and the profession will be brought before the meeting. The question of Poor-law Medical Reform is just now attracting very considerable public attention; and, as Mr. Corrance has given notice of his intention to bring on a discussion of the subject in the House of Commons on the 21st, it is most desirable that, whatever may be the conclusion at which the House shall arrive after hearing his statement, there should be no appearance even of falling off in earnestness on the part of the friends of the cause. We, therefore, trust there will be a full attendance of members and friends of the Association. In the evening at half-past six the annual banquet will take place. Gentlemen desirous of attending the dinner should at once write and announce their intention of so doing to Mr. J. Wickham Barnes, Honorary Secretary, 126, Gower Street, Bedford Square. We also urge on all gentlemen interested in this question to immediately communicate with such members of Parliament as they may happen to know, and urge them to attend and support Mr. Corrance's motion.

#### MANCHESTER AND SALFORD SANITARY ASSOCIATION.

At the last meeting of the Manchester and Salford Sanitary Association, the serious increase of small-pox in the city came under discussion, and it was unanimously decided to support the corporation in their attempts to institute disinfecting ovens in various central parts of the town. The state of the river Irwell was then discussed; and, it being considered futile to urge the corporation to petition Parliament

in the matter, it was suggested that a public meeting should be called under the auspices of the Society, to direct attention to the foul and poisonous character of the stream of liquid mud which rolls past our doors under the pleasing verbal fiction of a river. The chairman, Dr. Noble, opposed this resolution, on the grounds that the duty of the Society was scientific, not practical; that its function was to suggest, not to step into the gladiatorial arena of debate; adding that, by keeping aloof from public inspection, they threw a kind of glamour over society, and so stood for more than they were. This argument did not weigh much with some of the members, who remarked that the Society had in truth little to fear from, for they had little to lose by, a public appearance; that at present the Association was looked upon as a hole-and-corner affair; and that it was time that they were, as a sanitary society, of some sanitary value to the town, or that they voluntarily ended their existence. The "happy despatch" was not then administered, but the subject will be taken up again at the next meeting. If the Society come to an end, it will have to be recorded of them that, they at least instituted the first set of reliable statistics of disease in the English provinces.

#### MEDICAL SOCIETY OF LONDON.

DR. HABERSHON has been chosen Lettsomian Lecturer in the Medical Society of London, in place of Dr. Hyde Salter, who has resigned the appointment.

#### ROYAL COLLEGE OF SURGEONS.

At a meeting of the Council yesterday, the 13th instant, Messrs. Thos. Spencer Wells of Grosvenor Street, and George Critchett of Harley Street, the recently elected members of the Council, were sworn in and took their seats as such. At the same meeting the following annual elections took place. Mr. George Busk, F.R.S., Consulting Surgeon to the Seaman's Hospital, Greenwich, was elected President, in the vacancy caused by the retirement of Sir William Fergusson, Bart.; and Messrs. Henry Hancock of the Charing Cross Hospital, and Mr. Thos. Blizard Curling, F.R.S., Consulting Surgeon to the London Hospital, were elected Vice-Presidents. Mr. Timothy Holmes, B.A. Cantab, was elected Professor of Surgery and Pathology; Mr. W. H. Flower, F.R.S., Professor of Comparative Anatomy and Physiology; Mr. Erasmus Wilson, F.R.S., Professor of Dermatology; and Dr. Humphry, F.R.S., Lecturer on Anatomy and Physiology. Dr. A. Farre, Dr. Barnes, and Dr. Priestley, were elected Examiners in Midwifery. The following committees were also nominated: *Museum*, Mr. Holden, Mr. Birkett, and Mr. Erichsen; *Library*, Mr. Simon, Mr. Gay, and Mr. Wilson; *Jacksonian*, Dr. Humphry, Mr. Paget, and Mr. Hewett; *General Purposes*, Sir W. Fergusson, Mr. Le Gros Clark, and Mr. Charles Hawkins; *Audit*, Mr. H. Lee, Mr. Spencer Wells, and Mr. Critchett. Mr. T. Madden Stone was re-elected Clerk, an appointment which, with that of the former one of Librarian, he has now held for forty years, during which he has served the interests of the College and all its members with unsurpassable zeal and fidelity.

#### TESTIMONIAL TO DR. HALFORD.

THE *Melbourne Argus*, of May 20, says that Professor Halford has been presented with a testimonial, consisting of a handsomely-bound book and a purse of one hundred and twenty sovereigns, as a recognition of the merits of his method of treating cases of snake-bite by the injection of ammonia. The presentation was made by Mr. J. Wilberforce Stephen at Scott's Hotel, in the presence of a considerable number of medical and lay gentlemen. In making his acknowledgments, Professor Halford gave an interesting explanation of the circumstances which had led to his discovery, and expressed his belief that his mode of treatment was capable of extension to constitutional diseases. An influential committee was then appointed by those present to wait upon the Government in order to ask that a sum of money might be placed at the disposal of Professor Halford to enable him to make experiments in this direction.

## DRS. RICORD AND DEMARQUAY.

It is proposed to take advantage of the presence in London of our eminent confrères Drs. Ricord and Demarquay, on a mission of sympathy and acknowledgment from their countrymen, to invite them to a banquet, at which may be expressed the cordial sentiments entertained towards them personally, and our admiration of the devotion of themselves and their colleagues to their suffering fellow-countrymen during the siege of Paris and throughout the war. MM. Ricord and Demarquay were the chiefs of the great ambulances supported by the French press, and gave continued and distinguished proofs of their professional zeal and fine examples of the high principles which, under such circumstances, never fail to actuate the members of the medical profession in all countries. Sir William Fergusson, Bart., will preside. Mr. Busk (President of the Royal College of Surgeons), Mr. Hilton (President of the Pathological Society), Mr. Paget, Mr. Curling (President of the Royal Medical and Chirurgical Society), Mr. Hancock, Mr. Erichsen, Mr. Erasmus Wilson, Sir Henry Thompson, and Mr. Ernest Hart, will form the committee of arrangement; and gentlemen who wish to take part in this act of international courtesy, are requested to signify at once their intention to be present to Sir Henry Thompson, 35, Wimpole Street, or Mr. Ernest Hart, 42, Harley Street, the Honorary Secretaries.

## FESTIVAL OF THE FELLOWS OF THE ROYAL COLLEGE OF SURGEONS.

AFTER the annual election of members of the Council of the Royal College of Surgeons on Thursday last, the Fellows, to the number of about ninety, dined together at the Albion Tavern, under the chairmanship of Mr. Henry Douglas Carden of Worcester. Amongst the visitors were Sir A. Armstrong, the Director-General of the Naval Medical Department; the Presidents of the Medical Council (Dr. Paget), of the Royal Colleges of Physicians and Surgeons (Dr. Burrows and Sir William Fergusson, Bart.); Dr. Dalrymple, M.P.; Dr. Sayre of New York; etc.

After the usual loyal toasts, that of "The Navy, Army, and Reserve Forces", was given by the Chairman, and responded to by Sir A. Armstrong, Mr. Bloxam, and Mr. Cooper. "The Medical Council" was proposed in felicitous terms by Dr. Donald Dalrymple, M.P., and the President replied in an able speech.

Dr. ORSBORN of Bitterne, Southampton, said: I have the honour of proposing the next toast—an honour which I should most fully appreciate were it not for the consideration that I am altogether unqualified for this important duty, which ought to command greater erudition, a more familiar acquaintance with the institutions that are the subject of the toast, and a higher degree of eloquence than I can possibly attain. The toast is, "The Medical Corporations of this Kingdom"; and when we remember the great and important influence which these institutions have exercised, and must of necessity continue to exercise, over the destinies of our profession, it is impossible that such a toast can be received with indifference in an assembly composed of medical men. The Royal College of Physicians has fostered some of the ablest men who have adorned the ranks of our profession and contributed to its scientific advancement—men whose names will go down to posterity surrounded with a halo of brightness which the lapse of ages can never dim, which the revolution of centuries can never impair. And to us in the present day it is a matter of congratulation that the mantle of these distinguished individuals has fallen upon one who, as President of the College, is fully competent to sustain the honour which has devolved upon him with dignity and with credit, and advantage to the institution over which he so ably presides. [Cheers.] Of the College of Surgeons I am bound to speak in terms of admiration and respect. We cannot mention that noble institution without calling to mind the memory of one whose name will ever rank amongst the greatest of our race—one who was a giant in his day (for in relation to anatomy and surgery Hunter was as great as is Shakespeare in relation to our own dramatic literature). He can never be surpassed, probably will never be equalled; and his vast labours have raised to his memory a monument noble as it is enduring. Other luminaries of greater or lesser magnitude have shone forth on its horizon; but amongst these are probably

few who will reflect greater honour on their noble institution than will he who is at present the occupant of its presidential chair—whose practical skill and grand surgical achievements have won for him a reputation that has extended throughout the civilised world. And now, gentlemen, let us say one word on behalf of the Society of Apothecaries—a body which has deserved well of our profession, and of which I would fain speak in terms of considerate respect. I cannot forget that probably one of the proudest moments of my life was that when I escaped from its portals carrying with me its licence to practise. It may not have done all that we could have wished, but it has done much towards promoting a higher standard of medical education; and in this respect has contributed towards the advancement of the science of our profession and its practice as an art. [Cheers.] I have the opportunity and the privilege of associating with this toast "The Representative Institutions of America"; and I do so with the greater pleasure from the circumstance that we are this day honoured by the presence of Dr. Sayre, a distinguished member of our profession from New York, a gentleman who has won renown by his practical benevolence and bold achievements in surgery. We all feel a great interest in everything relating to our transatlantic brethren. We know them to be characterised by a strong tendency "to go ahead"; we are cognisant of the valuable improvements they have made in surgical practice and of their researches in scientific and practical medicine; and we are willing to acknowledge that we are indebted to them for many important additions they have made to the literature of our profession. I am persuaded you will join with me in the expression of a hope that those difficulties which have for some time existed and led to an estrangement between the two peoples may speedily be removed, and that henceforth there may be between them no other rivalry than such as may arise from a desire to see which can contribute the most largely towards the promotion of the interests and welfare of our common race. Let us hope, gentlemen, that those clouds which have been so long looming in the distance may now be dispersed, and that there may burst over both nations an unclouded sunshine of prosperity and peace. [Cheers.]

Dr. Burrows, Sir W. Fergusson, and Dr. Sayre, responded.

Sir W. FERGUSSON expressed his gratification with the manner in which the toast had been so pleasingly brought before the meeting by Dr. Orsborn. The President of the Royal College of Physicians had responded in such comprehensive terms that he might rest satisfied with declaring his assent to all that had been said by his friend Dr. Burrows. He thought, however, that it was incumbent on him to say a little more. He was glad to perceive that the toast of the College of Surgeons had been so well received; yet, after all, they were only drinking their own health as it were, for they in a manner represented their own College. In doing so they had, however, evinced their respect for the sister institution, and in particular for the College of Physicians. He was specially glad to corroborate the statement of Dr. Burrows about the harmony which prevailed between the two Colleges in regard to the development of a conjoint board for the examination of those desirous of entering the medical profession. For the College of Surgeons he could say, with the utmost sincerity, that the best feelings prevailed towards the physicians. There was respect, affection—he might almost say love—towards the sister institution; and so much did the latter feeling prevail that a bond of matrimony seemed not far distant which would give a strength and unity to the profession as a whole, such as had often been talked of but had never yet been realised. [Cheers.] The Council of the College of Surgeons had cordially gone into the consideration of a scheme for a conjoint board of examination; and he was strongly of opinion that on such a board their sister institutions, which represented so large a portion of the profession in England, should have a proportionate position. A board of examiners distinct from these institutions had been proposed; but he was firmly impressed with the opinion that, whilst other kindred institutions were duly represented, the main pillars of the proposed one portal should be formed by and from the two Colleges which had long and fully represented the profession in this country. It was well that on such an occasion as this the Fellows should toast their own institution. They must bear in mind that it was the head-quarters of some 15,000 of the practitioners in Britain; and, whatever defects there might be about it, there was much that they might all be proud of. He would only refer to the great museum which was their own; and, in particular, as evidence of the activity which prevailed within the walls of the Colleges, to those numerous additions to the collection which had been made since last year, and which had been specially displayed that day for inspection. Some of them were rare, others unique, and such, therefore, as had never been seen previously.\* [Loud cheers.]

\* Sir William alluded to the interesting preparations of the skeleton, stomach, etc., of the young hippopotamus, which had attracted particular attention, and of which an account was lately published in the JOURNAL.

Dr. SAYRE responded in the following terms:—I am so overwhelmed by the applause with which you have been kind enough to receive the sentiment in honour of my country, that I feel totally inadequate to express in language a proper sense of my gratitude for the honour conferred, not upon me, but upon my native land. I most sincerely regret that some one more competent than myself is not present to respond in fitting language to the high compliment you have been pleased to pass upon American surgery. My distinguished friend Sir William Fergusson has just alluded to the "go ahead" principle exhibited by American surgeons, and to the desire now existing among the profession in England to unite the two branches of the profession, which at the present time are so distinctly separate. It is my impression, that one of the principal reasons for the rapid strides in our profession in America is the fact that we have already had the marriage ceremony performed, and are thus living in a normal professional condition, which necessarily keeps us in a healthy, active, and vigorous vitality. Celibacy, even in the church—inasmuch as it is in violation of the laws of nature—is necessarily injurious to the physical condition of man; so in our profession, things which naturally assimilate together, and to be perfect must be united, should never be separated by conventional rules. It is impossible for a man to be a thoroughly qualified surgeon, unless he be also a competent physician. Neither can a man be a properly qualified physician, unless he be also competent to judge of the proper time when to call in the aid of the acting surgeon. As far as my observation goes, the difference between English, French, and German medicine and surgery is this. We go to France to learn the alphabet of our profession, correctness of diagnosis, to be able to give the name, nature, and exact locality of any given disease; and if, when death takes place, the *post mortem* examination reveal the correctness of the diagnosis, the Frenchman is content. We go to Germany to learn the exact pathological changes that have occurred during disease, and through it. Months, and even years, of the most laborious scientific research have been spent in the minutest investigation by the microscope, and by chemical tests and analyses of the different structures of the human body, to ascertain the various changes that have been produced in their composition by different diseases. And both of these great nations have contributed much to the advancement of our profession. But we have to come to the plain practical sense of old John Bull for the application of the best means of preventing suffering, and relieving man from the various ills to which human flesh is heir. [Cheers.] But, Mr. President, you must excuse me. I came to this country, not to make dinner-speeches, but to study and to learn; and I am happy to say that I have been amply repaid for my time and trouble. I have had the privilege of witnessing the most difficult operation performed by that master-hand, Spencer Wells, who was perfectly ready with the only appropriate relief at the moment of each particular emergency, thus proving himself to be the perfect master of the situation. I have also had the honour of seeing many operations performed by that most dexterous and scientific manipulator, Sir Henry Thompson, and have learned much from his pithy and practical observations. I have looked with wonder and amazement at the number and extent of your hospitals and various public charities, and the almost innumerable crowds that daily attend them—making a field for practical study scarcely equalled on the face of the globe. But what most commanded my admiration was the wonderful museum in your Royal College of Surgeons, the nucleus of which was founded by the incessant labour of one of England's greatest surgeons—the immortal John Hunter. The collection and preservation of the labours of this great man's life, and the constant addition made thereto, and the careful and scientific manner in which they are arranged and preserved, must command for England the admiration of the civilised world. Mr. President and gentlemen,—Pardon me for detaining you so long, and permit me to close with this single sentiment—that, forgetting and forgiving all past differences, let our future efforts be to emulate each other in our endeavours to alleviate human suffering, and to promote the best interests of mankind. [Applause.]

"The Provincial Schools" was given by Mr. HANCOCK, one of the Vice Presidents of the College, who said that he proposed the health of a body of gentlemen who did good service, and who did so to within a few years ago under difficulties. He alluded to the lecturers at the provincial schools of medicine. A very few years ago these gentlemen were placed in a most anomalous position; they were told they were competent to teach the theoretical portion of medical study, or they might teach the practical, either one or the other, but that they were incompetent to teach both; and, consequently, the student was obliged to come up to London to complete his education. At the present time that anomaly no longer existed. They now had a fair field and no favour; and he sincerely trusted that the provincial schools would not only vie with each other, but with the schools of this great metropolis,

in their endeavours to maintain and promote the welfare, the dignity, and progress, of our noble profession. [Cheers.]

Mr. VOSE SOLOMON of Birmingham replied.

"The Metropolitan Schools" was ably given by Dr. HUMPHRY, F.R.S., of Cambridge, who had no doubt of the hearty acceptance of the toast, which was that if not of the authors of our professional existence, yet certainly of our nursing mothers, from whom we had drawn milk rich with the very cream of knowledge, and which were among the most important institutions in the country. For what would those corporate bodies of which mention had just been made—what would the profession—be without the metropolitan medical schools? By that he meant the metropolitan medical teachers, who had a great work to perform, and were under a great responsibility. They had received a noble heritage—the heritage of a banner inscribed with the names of Abernethy and Cooper, of Lawrence and Travers, of Bright and Latham, and others of equal renown; and they bore that banner bravely forward, and would hand it on illuminated with additional names no less bright than those of their predecessors. [Cheers.] Dr. Humphry doubted not that those who heard him had left their respective schools with the same feelings of filial regard and honest respect for their teachers which he had carried away with him from St. Bartholomew's thirty years ago; and that many were pleased, with him, to see some of their teachers present, still active and young and fresh in work. The feelings which he carried away with him from London he had retained during the interval; and now that he was, by the suffrages of the Fellows, brought again into contact with those teachers in the Council of the College of Surgeons and in the Committees of the College of Physicians and Surgeons, who had held so many meetings and done so much to promote the matrimonial alliance that had been alluded to between the two Colleges, he could honestly say that increasing knowledge of those gentlemen in another capacity had been productive of increased respect. He found them actuated by the simple, sincere desire to promote the welfare of the profession; and their efforts to maintain the position, and, if possible, add to the influence and dignity of their respective corporate bodies, were consequent on the conviction which the profession, and, he believed, those present fully shared, that the prosperity of those bodies was intimately associated with the prosperity and status of the profession. He spoke of the good work which was being done in the metropolitan schools, and concluded by associating with the toast the name of Mr. Holmes Coote, so well known to the Fellows by the practical and scientific work he had done, and to the students by the ability with which he instructed them, and the courtesy which he showed them. [Applause.]

Mr. HOLMES COOTE, of St. Bartholomew's Hospital, replied that the great honour conferred upon him to respond was unexpected. He felt much gratified to think that the London schools of medicine still retained the confidence of the profession, and he thought that much of that confidence was acquired by the greater freedom of professional intercourse, and the valuable medical and surgical contributions which could now be readily obtained from all known quarters. The schools of England, Scotland, and Ireland, the patient reports so admirably got up and printed by our brethren in America—these were advantages which those of past ages did not enjoy. [Cheers.]

"The Chairman" was proposed, with his usual eloquence, by Mr. JAMES PAGET, F.R.S., who said that, as an old and esteemed friend, a distinguished surgeon, and one of the best representatives of the provincial division of the profession, Mr. Carden's great knowledge, skill, and common sense had gained for him the complete confidence of both the profession and the public in a wide field of practice; and in the same field his personal character had won respect not only for himself, but for all his brethren. And for this all were indebted to him; for the estimation in which our profession was held depended more on the provincial than on the metropolitan members. They lived nearer to their neighbours; their social influence was more felt; the good they did, and the good tone of their lives, were closely observed, and misconduct was more evident and more likely to be regarded as discreditable to the whole profession. Mr. Carden's health, therefore, as that of a good surgeon and a good example, ought to be drank very heartily. [Cheers.]

The CHAIRMAN feelingly and eloquently returned thanks, and proposed the health of the Honorary Secretary, Mr. T. Carr Jackson, who was enthusiastically cheered; especially when he announced, before sitting down, that Sir William Fergusson, Bart., the greatest, as he was the most popular surgeon of the day, had consented to take the chair at the next annual festival.

As showing the great interest taken in the annual election of Fellows into the Council of the College it may, as it deserves to, be recorded that gentlemen attended from distant provincial towns, as will be seen in the accompanying list. Messrs. Adams (Maidstone), Allard (Tewks-

bury), Ashley (Staines), Anderson (Derby), Ambler (Hemel Hempstead), Bell, Brown, and Hutchins (Rochester), Carden (Worcester), Cattlin and Rugg (Brighton), Crosse (Norwich), Curling (Ramsgate), Dalrymple, M.F. (Norwich), Fox (Broughton, Hants), Green (Bristol), Havers (Berkhamstead), Holman (Hurstpierpoint), Hulme (Guildford), Jones (Brackley), Lowe (Burton-on-Trent), Lowes (Gosport) Lush and Scriven (Weymouth), May (Reading), Monckton (Rugeley), Morris (Spalding), Nankivell (Chatham), Nicholls (Chelmsford), Orsborn (Bitterne), Pern (Botley), Orton (Narborough), Prankerd (Langport), Ryatt (Newbury), Smith (Stevenage), Heckstall Smith (St. Mary's Cray), Southam (Manchester), Spurrell (Belvedere), Symonds (Oxford), Thomas and Tait (Birmingham), Thomson (Ross), Ward (Huntingdon), Wilbin (Southampton), and Winchester (Maidenhead).

## ASSOCIATION INTELLIGENCE.

### BRITISH MEDICAL ASSOCIATION: ANNUAL MEETING.

THE Thirty-ninth Annual Meeting of the British Medical Association will be held in Plymouth, on Tuesday, Wednesday, Thursday, and Friday, the 8th, 9th, 10th, and 11th of August next.

*President*—E. CHARLTON, M.D., D.C.L., Physician to the New-castle-upon-Tyne Infirmary.

*President-elect*—JOHN WHIPPLE, Esq., F.R.C.S., Consulting Surgeon to the South Devon and East Cornwall Hospital.

An *Address in Medicine* will be delivered by GEORGE JOHNSON, M.D., F.R.C.P., Professor of Medicine in King's College, London.

An *Address in Surgery* will be delivered by JOSEPH LISTER, Esq., F.R.S., Professor of Clinical Surgery in the University of Edinburgh.

*Notices of Motion*.—The following notices have been given.

The PRESIDENT OF THE COUNCIL: Rule 4. To insert "President-elect", and to omit "Secretary".—Rule 6. To expunge this rule, and to substitute the following: "Each retiring President of the Association and President of Council shall be appointed a Vice-President for life by a vote of the members at the Annual Meeting."—Rule 7. To add "the Vice-Presidents" after President-elect; to insert the word "and" between President of the Council and Treasurer, and to erase "and the Secretary".—Rule 8. In this and every rule where "District" is prefixed to Branch, to erase the word "District", and to erase the words "the Secretary of the Association".—Rule 9. To omit the words between "The President of the Council" and "shall be elected".—Rule 10. To omit the words between "The Treasurer" and "shall be elected".—Rule 11. To erase the words after "There shall be one paid Secretary" in first section, and to substitute "who shall reside in London, and devote his whole time to the business management of the Association and of the JOURNAL office". To erase the words "otherwise" in seventh line and "an annual or special" in eighth line, and to insert "each Annual Meeting".—Rule 13. To erase the words "Secretary shall call", and to substitute "President of Council shall direct to be called".—Rule 14. Between "shall" and "be recommended", to insert "express his desire in writing, and shall be".—Rule 15. To add "Members may be admitted on and after July 1st in each year, and the subscription for such part of a year shall be half a guinea". To erase the words after "such member" in eighth line, and to substitute "as long as his subscriptions remain unpaid, provided due notice shall have been given of such withholding".—Rule 16. To erase the words after "from his" in fourth line, and to substitute "liabilities to the Association".—Rule 24. In tenth line, to insert "a copy of the laws" between "Association" and "and".

Dr. STEELE (Liverpool): Election of Committee of Council. Every associate, who is a member of the Council, and desirous of a seat on the Committee of Council, shall send to the General Secretary, not later than \_\_\_\_\_ months prior to the Annual Meeting of the Association, a declaration signed by himself, and in the following terms: "I, A. B., of C., member of the British Medical Association, hereby declare that I am a candidate for a seat on the Committee of Council of the said Association. (Signed) \_\_\_\_\_." Together with a nomination-paper signed by six members of the Association, in the following terms: "We, the undersigned, members of the British Medical Association, certify that A. B., of C., is a fit and proper person to be a member of the Committee of Council of the said Association." The names of the eligible candidates, with the names of the six associates by whom they shall have been respectively nominated, shall be published in the BRITISH MEDICAL JOURNAL not later than \_\_\_\_\_ months prior to the Annual Meeting of the Association.

Mr. NICHOLSON (Hull): To alter Law 16, line 2. For "three", insert "two".

Dr. WADE (Birmingham): In Law 8, Paragraph No. 3, of the duties of Council, to alter "ten" into "twenty-five"; and to omit the words "and one Secretary from each Branch".

*Invitation to Torquay*.—The members of the medical profession at Torquay request the pleasure of the company at luncheon, on Saturday, August 12th, at 3 o'clock, of any member of the British Medical Association residing beyond fifty miles from the place. Their object in this limitation as to distance is that of furnishing an opportunity to strangers unfamiliar with Devonshire to become acquainted with Torquay and its immediate neighbourhood. Any member who may wish to favour them with his presence, will oblige by notifying the same at his early convenience—and not later than on the Wednesday of the Plymouth meeting—to the Honorary Secretary, Dr. Powell, Infirmary, Torquay.

*Special Railway Arrangements*.—First and second class ordinary and express return tickets issued at any South Devon, Cornwall, or West Cornwall Station to Plymouth, on August 7th and following days, will be available for the return journey any day up to and including Monday, August 21st. First and second class return tickets, at single fare for the double journey, available as above, may be issued from any Station on these lines to Plymouth, or from Plymouth to any South Devon, Cornwall, or West Cornwall station, on August 7th and following days to August 21st inclusive, to the members of the British Medical Association producing a certificate or the Association card of membership. Unless such documents are produced, return tickets at ordinary or express fares must be issued. When tickets at single fare for the double journey are issued, the booking clerks must write "return" upon them, and place their initials below the word "return". Ordinary tickets endorsed "return" will be available by express trains without payment of the difference of fare.—The Bristol and Exeter Railway have agreed to the same conditions as the South Devon, Cornwall, and South Cornwall Railways.—The South Devon, Cornwall, and West Cornwall Railways have also promised to convey any instruments, medical and surgical appliances, etc., for the Annual Museum, at *half the usual fares*, at the owner's risk.—Members intending to avail themselves of the return tickets should communicate at once with Dr. Littleton, Lansdown Terrace, Plymouth.

Gentlemen desirous of reading papers, cases, or any other communications, are requested to give notice of the same to the General Secretary at their earliest convenience.

T. WATKIN WILLIAMS, F.R.C.S., *General Secretary*.

13, Newhall Street, Birmingham, June 13th, 1871.

### THE ANNUAL MEETING IN 1871.

THE Local Committee appointed by "The Three Towns", Plymouth, Devonport, and Stonehouse, to prepare for the annual meeting of the British Medical Association in 1871, have much pleasure in acquainting the members that they have succeeded in obtaining the cordial co-operation and assistance of the civil and military authorities; so that every facility will be furnished them for inspecting this naval and military arsenal; Her Majesty's ships of war in the Hamoaze and Plymouth Sound; Her Majesty's dockyards at Devonport and Keyham; the Royal William Victualling Yard and the naval and military hospitals in Stonehouse; the Breakwater and its lighthouse; the Eddystone Lighthouse; the Plymouth Citadel, the Hoe, and the forts recently erected within a radius of five miles.

By the kind permission of His Grace the Duke of Bedford, the Right Honourables the Earl of Mount Edgcumbe, the Earl of St. Germans, and the Earl of Morley, and other gentlemen, opportunities will be offered to the members of surveying the grounds and the extensive views commanded in the parks attached to their mansions on the banks of the Tamar and Plym; whereby they will be enabled to pass in review the objects before-named, as well as the magazines at Bull Point; Antony House, the seat of W. H. Pole-Carew, Esq., whereat is preserved Holbein's portrait of Dr. Butts, Physician to Henry VIII; Ince Castle, the residence (*temp.* Charles II) of the Wit of Cornwall, Killegrew; St. German's Church, the site of Cornwall's ancient Cathedral, and Port Eliot (the ancient Priory); Trematon Castle, the residence of the Norman Earls of Cornwall; the late Brunel's master-piece, the Royal Albert Bridge at Saltash; Landulph Church; Buckland Abbey, the seat of Drake, the great circumnavigator; Maristowe; Cothel House; Pentillie Castle; Morwell Rocks; Harewood, the scene of the fair Elfreda's treachery; and other objects of interest in a trip of twenty miles by steamboat.

Other excursions will be arranged, with the sanction of the Directors, etc., of the Railways—to Launceston Castle, the Ancient Cornish stronghold; to the Saxon Abbey at Tavistock; to Endsleigh Cottage; and to the wild and romantic scenery of Dartmoor.

A most interesting excursion into West Cornwall has also been planned to take place during the Association's visit.

*The Royal Institution of Cornwall*, under the presidency of Mr. D. J. Henwood, F.R.S., in order that opportunity may be given to the members of the British Medical Association for seeing the most noted and interesting objects in the extreme West of England under the most favourable circumstances, will make its annual excursion on Monday and Tuesday, the 14th and 15th of August. Penzance, the approach to which affords an excellent view of St. Michael's Mount, will be the place of rendezvous on the first day; and, after an inspection of this most westerly and mildest of British Winter resorts, the party will visit the Logan Rock and Land's End, concluding the day with an evening meeting at St. Just. On the morrow, the famous mine of Botallack will be explored, the fine northern coast line will be skirted, and the excursion will terminate in the picturesque neighbourhood of St. Ives, in time for the return journey to Plymouth. The line of route presents a great many remarkable objects of antiquity, especially primeval ones.

A steamer will be engaged to make short trips daily, and at stated hours, during the visit of the Association, thus enabling those members who may not be desirous of hearing the delivery of certain papers, to spend their time agreeably in viewing the rich scenery of the port.

#### PAPERS FOR THE ANNUAL MEETING AT PLYMOUTH, 1871.

THE following are the names of the Honorary Secretaries of Sections for the approaching Annual Meeting.

*Medicine*.—Dr. Clay, Plymouth; Dr. Wade, Birmingham.

*Surgery*.—W. P. Swain, Esq., Ker Street, Devonport; C. Steele, Esq., Clifton, Bristol.

*Midwifery*.—Dr. J. Rolston, Stoke, Devonport; Dr. Phillips, 26, Finsbury Square, London.

*Public Medicine*.—Dr. Row, Devonport; David Davies, Esq., Queen Square, Bristol.

Gentlemen proposing to read papers or to forward communications for the Annual Meeting are requested to communicate with the least possible delay with the Sectional Secretaries, in order that the titles of their papers may be duly announced, and that arrangements may be made for the order in which they are to be read. Abstracts should at the same time be prepared, and communicated beforehand to the JOURNAL, in order that copies of such abstracts may be issued by us for the simultaneous use of the other medical papers.

#### THE ANNUAL MUSEUM.

THE "Annual Museum" of this Association will be open during the four days of the meeting, for the exhibition of:

1. The latest inventions in medical and surgical instruments and appliances of every kind. Also, for the special exhibition of ancient and modern fracture apparatus, or diagrams of such, thus setting forth the history of the treatment of fractures from the earliest records down to the present day.
2. New drugs and their preparations.
3. New articles of diet for invalids.
4. Pathological Specimens; also photographs, casts, etc., illustrating disease.
5. New works on medicine, surgery, etc.
6. Models or drawings of any object of professional interest not included in the above list.

*Notice to Exhibitors*.—Application should be made as soon as possible; at the same time giving a list of the objects to be exhibited, and mentioning the space required. All objects sent must have a description attached. Parcels for the Museum should be addressed—"British Medical Association, the Assembly Rooms, Plymouth; care of H. Greenway, Esq." They must be delivered on or before July 31st, and be removed within three days after the termination of the meeting. Expenses of carriage and all risk must be borne by the exhibitors. A card, bearing the name and address of the exhibitor, must be enclosed in each package, ready to be fixed on the outside. All communications respecting the Museum to be addressed to "Henry Greenway, Esq., Surgeon, Plymouth", the Secretary for that department.

#### YORKSHIRE BRANCH.

THE annual meeting of the above Branch will be held at the Infirmary, Bradford, on Wednesday, 26th July, at 2.15 P.M.; R. H. MEADE, Esq., President, in the Chair.

The dinner will take place at the Victoria Hotel, at 5 P.M. Tickets (exclusive of wine), 7s. each.

Gentlemen having papers or cases to communicate, or who intend dining, are requested to send an early intimation to the Secretary, so that the necessary arrangements may be made.

W. PROCTER, M.D., *Honorary Secretary*.

York, July 12th, 1871.

#### SOUTH-EASTERN BRANCH: ANNUAL MEETING.

THE twenty-seventh annual meeting of this Branch was held at the Steyne Hotel, Worthing, on Friday, June 30th.

Mr. JOHN M. BURTON (Lee), the President for 1870-71, opened the proceedings, and briefly referred to the operations of the Association during the past year. General politics had so occupied the time of Parliament, that there was no prospect of carrying a Medical Reform Bill this session. The Bill that was introduced by the proprietors of the *Lancet* had fallen still-born from the authors' hands. As regarded the affairs of the Branch, it was quite gratifying to mention how the district meetings had flourished during the past year. The meeting at Dartford at the beginning of the year was a great success. One important point in connexion with these meetings was, that they brought the members together from all parts, and formed a recruiting-ground for the Association. With respect to his own position as President, he had had exceedingly little to do; but he was afraid his successor would have a great deal more responsibility devolving upon him. After thanking the members for the kindness they had shown him, Mr. Burton vacated the chair, and introduced his successor, Dr. Tyacke, to the meeting.

Dr. TYACKE, on taking the chair, was received with considerable applause.

*Vote of Thanks*.—Dr. ALFRED HALL (Brighton) proposed—"That the thanks of the members be given to the President and Vice-Presidents for the past year, Mr. John Burton, Dr. Jeaffreson, and Mr. Pinching." All those who were present at the last meeting would not fail to remember how admirably the President fulfilled his duty on that occasion. It was one of the most pleasant meetings he had ever attended; and the members living at a distance regretted having to leave early. With regard to the other two gentlemen mentioned in the resolution, there could not possibly have been appointed more efficient officers.

The resolution, having been seconded, was carried unanimously.

Mr. BURTON, on behalf of himself and colleagues, returned thanks.

*President's Address*.—Dr. TYACKE, who, on rising, was greeted with cheers, said: My grateful thanks are due to you, and most sincerely and cordially do I proffer them, for the honour you have been pleased to confer on me in electing me to the position which I now occupy. My claim to such a distinguished mark of your approbation is not such as I should have desired it to be; and, had I been present at the meeting at which the election took place, I feel that I should have ventured to suggest a more worthy representative, especially for this occasion. Residing as I do at the western extremity of our district, inconvenient means of communication and other impediments have prevented me from attending the meetings of the Association nearly so frequently as I should have desired; but, as a member of some thirty years' standing, I have always felt very great interest in the Association, as the most effectual means of promoting the interests of the medical profession, as well as of extending the results of its practical and scientific investigations for the benefit of the public at large. At the annual meetings of our Branch, I believe it is desired that the proceedings should be of a sociable, rather than of a scientific kind; and that long papers and long speeches should be transferred to our district meetings. I must not, therefore, occupy your time by many words. Our weekly JOURNAL and other periodicals fully detail the current topics connected with medical science and policy, so that a general *resumé* of them is not desirable; but perhaps a few words may be expected from me in reference to the still prevalent epidemic—small-pox. Notwithstanding that Dr. Seaton and others had warned us that, in consequence of the neglect by many of the prophylactic influence handed down to us from Jenner, the enemy might any day fall on us unprepared, such a virulent attack of the disease was little anticipated either by the profession or by the public. Like a neighbouring nation, lulled by the prestige of former victories, they little heeded the means of defence within their

reach, till the enemy appeared around and among them. The havoc that has followed is too well known. But may we not hope that the consequent panic may lead to good, by rousing the careless to a keener sense of their danger, and thus, by the more general employment of vaccination and revaccination, leave at least the present generation fairly assured against a return of the disease in an epidemic form? With regard to the future, however, the remembrance of the past must leave us apprehensive of the recurrence of the former indifference among the many, and of the want of confidence in the value of vaccination among the few. And by what means can such a result and its consequences be guarded against? In the first place, by speedy legislative action. Vaccination should be performed within a limited period, under penalty; and the result should be certified by medical authority. And the importance of revaccination about the age of puberty should be urgently inculcated. The Vaccination Amendment Bill may effect probably as much as is practicable in these days, when people claim the right, for profit or pleasure, or other selfish motive, to endanger the health and lives not only of themselves and their own households, but also of the public at large. As regards sanitary measures in general, the ignorance and prejudices of the masses render the efforts of the enlightened few to a serious extent inoperative. Even strong governments in this country shrink from enforcing the law against proved violation of the most recent Sanitary Acts; and insatiable abuses are allowed to continue, to the danger of health and life, and increasing burden of local rates. Perhaps the only remedy for such a state of things—and it can be only gradually brought about—is the special education of the people in sanitary matters. They should be taught that the means for the prevention of disease are more important even than those for the cure of it. They should be instructed as to the conditions and circumstances that influence, favourably or prejudicially, their physical and moral well. To this end, efforts should be made in our parish and district schools, as well as in our higher educational establishments. Much might be effected by the ministers of religion, the city magistrate, and the country gentleman. But medical men, by position and knowledge, are especially qualified to assist in the promotion of education of the desired kind; and we shall be found, I trust, ready and desirous, at all times and on all occasions, to exert ourselves in the furtherance of sanitary measures, and to instruct the minds of those with whom we may have influence in a just appreciation of them. Most of us, in the treatment of diseases, especially of the typhoid type, must have observed that, in certain houses and localities, the usual remedies fail in their effect; that fevers of the severer kind are more than ordinarily fatal; and that convalescence from slight attacks is tedious or impossible without change to another more healthy district. Such cases frequently come under my observation, and I find it very difficult to persuade the patients or their friends that the obstacle to their recovery lies in the insanitary condition of their own houses and premises. It is not sufficient to inform them that the close tainted air they breathe and the impure water they drink are injuring their constitutions: the facts must be proved to them by examples in which they themselves are the subjects; and thus I have been able to convince many of the danger by which they are surrounded, after all attempts at persuasion had failed. Let us then, gentlemen, not only observe, but register, such sad but useful instances as in daily practice pass before us, as a means of persuading those whom ordinary reasoning cannot reach. I have ventured to occupy thus much of your time, gentlemen (and I thank you for so patiently bearing with me), by way of introduction to the more interesting occupation that awaits us. On quitting this room, Dr. Collet and other medical friends of Worthing will do us the honour of showing and explaining to us the system of water and drainage works that have been established in this place. The existence of such works here does great credit to those who have been instrumental in establishing them; and I trust that the beneficial results do not and will not fall short of their most sanguine expectation.

Dr. EDMUND YOUNG proposed—"That the thanks of the meeting be presented to Dr. Tyacke for presiding, and for giving so interesting an address." The few short concise rules which Dr. Tyacke had laid before the members were worthy of their most serious attention.

Mr. CORDY BURROWS (Brighton) seconded this resolution, and endorsed the remark as to the valuable nature of the address. In his opinion, the new Vaccination Bill was most imperfect. It appeared that any person could evade it by the payment of a fine of twenty shillings; and, having paid that fine once, he was no longer liable. It was quite clear that, in the interests of society, a much more stringent measure must be passed. He had written to certain members of Parliament on the subject, and he trusted that the objectionable clause would be removed. Mr. Burrows referred with much pleasure to the election of Dr. Tyacke, and referred to a meeting held by the Branch at Chichester twenty-five years ago, under the presidency of Dr.

M'Carogher, when the active interest taken in it by their present chairman added in no small degree to the enjoyment and gratification of all who then attended.

The resolution was unanimously carried.

The PRESIDENT thanked the meeting. He felt that his appointment would have been more suitably filled by a resident in the town where the meeting was held, and who would have given them some interesting and important local information.

*Report of Council.*—The following report of the Council was read by Mr. HODGSON, the Honorary Secretary.

The Executive Council of the South-Eastern Branch again have pleasure in reporting the continued increase and prosperity of the Branch. The number of its members at the time of our meeting last year was 304. That number has been reduced since by seventeen removals (four of them on account of death), and increased by twenty-six new members, making our present total 313. The deceased members were Dr. Hatton of Belvedere, Dr. Bacon Phillips of Brighton, Mr. Tippetts of Brompton, and Mr. Weekes of Hurstpierpoint. It is worthy of remark that the new members during the past year, as also during several preceding years, have come to us mainly from those parts of the Branch where the district meetings are most energetically carried out—namely, from East and West Kent, East Surrey, and East Sussex. Thus, of the twenty-six new members that have joined us during the past twelve months, only one is resident in West Surrey, and only two in West Sussex; of the thirty-four new members in the previous year, only one resided in West Surrey, and one in West Sussex; and of the forty-eight new members in the year before that, only one resided in West Sussex, and three in West Surrey. The members in West Sussex recently, with the approval of the Council, detached themselves from the West Surrey District, and formed a district by themselves, leaving West Surrey to do the same. With Mr. Harris of Worthing as Local Secretary, the West Sussex District held its first meeting in April last, which went off very cordially, though thinly attended; the latter circumstance being partly in consequence of the day being excessively wet. It is hoped that the fact of the present annual meeting being held at Worthing may lead to a further development of the West Sussex District.

Our renewed thanks are due to the District Honorary Secretaries, as it is certain that the district meetings contribute largely to the best interests of the Association in every way.

As the representative of the Branch in the Parliamentary Committee of the Association, the Council have again elected, with his consent, Dr. Holman of Reigate.

The Council, whilst congratulating their fellow-members of the Branch on the very small number of subscriptions remaining ultimately uncollected in this Branch for the year 1870, would yet urge upon them the great importance of paying them *much earlier in the year* than seems the custom with many of them. The more efficient and economical working of the Association would thereby be much promoted, and the duties of our Honorary Secretary (which, in so large a Branch, are necessarily arduous) would be somewhat lessened. The Council observe with much concern the large amount of arrears reported as due from members of the Association generally who are not members of Branches; and they trust that the measures about to be proposed at the general annual meeting at Plymouth by the Committee of Council will prove an efficient remedy for so serious an evil.

The Council regret that it has been found necessary to defer until the next session of Parliament the important subject of medical reform. Mr. Forster received the deputation of our Association with the assurance that it was impossible in this crowded session to pass any measure on this subject. The Association must press its claim to a favourable hearing next session, each of us then trying to help to the utmost of our power.

Dr. COLLET (Worthing) moved—"That the Report now read be approved and adopted." He expressed his hearty conviction of the importance of the district meetings. He had been present at two in that room, and one at Horsham; they were but thinly attended, although worthy of much larger congregations. Most excellent papers were delivered. The paper read by Dr. Martin was a very valuable one; and that delivered by Dr. A. Hall, he was sure, might have been given with benefit before a thousand people. They must look forward to larger meetings, and induce members to come, even though at a little personal inconvenience. The Honorary Secretaries were especially deserving of thanks. Judging by the manner in which his friend Mr. Harris, the District Secretary for West Sussex, performed his duties, he was sure they were fully entitled to the warmest acknowledgments of the meeting. Their labours in connexion with the Association might not have been really arduous; but, carried on all the year round, in the midst of daily work, they necessarily involved a large amount of self-denial and sacrifice of

time. With regard to the appointment of Dr. Holman, he (Dr. Collet) considered a most judicious selection had been made; for Dr. Holman was pre-eminently qualified for the duties of the office to which he had been appointed. Reference had been made to the Medical Reform Bill. He understood very little indeed of the subject of medical reform; but he was glad to see that the matter had been taken up, and he hoped they would see the fruits of it next year.

Mr. WORTHINGTON having seconded the motion, it was unanimously carried.

*Financial Report.*—The SECRETARY read the financial report, from which it appeared that the Branch was in a very flourishing condition. The balance in hand was £34:16:4, that of last year having been £32:7:4. The accounts had been duly audited.

Mr. CORDY BURROWS said that the step taken last year, in increasing the annual subscription from 2s. 6d. to 4s., in order to dispense with the district subscriptions and to reimburse the District Secretaries' travelling expenses out of the funds, had proved highly satisfactory. The usefulness of the Association had been materially advanced, and they left off with a very good balance. He moved that the accounts just read by the Secretary be approved.

Dr. HALL seconded the motion, which was unanimously carried.

*Next Annual Meeting, Officers, &c.*—Mr. BURTON said that the last annual meeting was held in Kent, the present was held in Sussex, and he thought that of next year should be held in Surrey. He moved that the meeting be held next year at the Crystal Palace, for Croydon. —Mr. NAPPER seconded.

Dr. HALL nominated Dr. Carpenter as President for the next annual meeting, and Drs. Hetley and A. Duke as Vice-Presidents.

Dr. SUTHERLAND seconded the resolution. He knew that Dr. Carpenter would make a most efficient and very worthy President; for whatever that gentleman took in hand he carried out to the fullest possible extent.

The resolution was unanimously carried.

The SECRETARY next reported the result of the scrutiny of the voting-papers. The votes were as follows.

*Fifteen Representatives of the Branch in the General Council:* John Armstrong, M.D.; R. L. Bowles, M.D.; J. Cordy Burrows, Esq.; John M. Burton, Esq.; Alfred Carpenter, M.D.; William Carr, M.D.; Frederick Fry, Esq.; Alfred Hall, M.D.; Constantine Holman, M.D.; Stephen Monckton, M.D.; Albert Napper, Esq.; T. Heckstall Smith, Esq.; James R. Stedman, M.D.; Nicholas Tyacke, M.D.; Edward Westall, M.D.

On the motion of Dr. WITHERS MOORE, the best thanks of the meeting were presented to the Executive Council for the efficient manner in which they had discharged their duties.

*Fifteen other elected Members of the Executive Council:* James H. Aveling, M.D.; Charles W. Chaldecott, Esq.; J. Cooper Forster, Esq.; Thomas Fuller, M.D.; Richard Gravely, Esq.; Horace Jeaffreson, M.D.; Thomas Joyce, M.D.; George Lowdell, Esq.; T. H. Martin, Esq.; James Reid, Esq.; George Tatham, Esq.; Charles Trustram, Esq.; John Underwood, M.D.; William Wallis, Esq.; John R. Woodell, M.D.

Mr. BURTON acknowledged briefly this vote of thanks, and, in an eulogistic speech, proposed the re-election of the Honorary Secretary, Mr. Hodgson. That gentleman had, he said, most admirably performed his duties—not going about them in a mere perfunctory way, but entering most thoroughly into the work; and the Association had derived the greatest benefit from his self-denying labours.

Dr. ARMSTRONG (Gravesend) seconded the proposal. He was quite sure that all men of business were fully aware of the vast importance of the office of Secretary, especially when filled by one who entered with heart and spirit into everything that came before him. That their present Secretary had discharged his duties in a most faithful manner, all the members had more or less an opportunity of judging. Dr. Armstrong took the present opportunity of making some remarks upon the importance of the district meetings. He could speak with considerable experience on this point, and was perfectly certain that they were not only beneficial to the profession generally—not only opportunities for mutual instruction; but that they were most advantageous to the individual members themselves. He could not remember having attended any meeting where he did not learn something worth taking away. He was quite sure that no man could prepare a paper for these meetings without himself deriving an immense benefit therefrom, to the improvement of his own mental calibre.

The PRESIDENT put the resolution to the meeting, and it was carried.

The HONORARY SECRETARY said he should be happy to continue to do his best for the Association; and he thanked most heartily the

members for their kind appreciation of his services. The only difficulty was, that the more one's private affairs prospered, the more was work of this sort likely to clash; and, as the Branch had now grown to such proportions, it did happen at times that he experienced considerable difficulty in getting through the work that had to be done. He again thanked them for the cordial feeling which had ever been shown towards him.

*Dinner, &c.*—This terminated the business of the meeting; and, vehicles being in readiness, the party, escorted by Dr. Collet and Mr. Harris, proceeded to the waterworks and sewage-farm on the outskirts of the town. On returning to the hotel, a capital dinner was provided in the handsome assembly room of the establishment, and between thirty and forty gentlemen sat down. A quantity of magnificent fruit and flowers was most liberally presented by Dr. Morgan of Henfield. Dr. Tyacke was in the chair, and Dr. Collet in the vice-chair.

## LANCASHIRE AND CHESHIRE BRANCH: ANNUAL MEETING.

THE Thirty-fifth Annual Meeting of this Branch was held in the Medical Institution, Liverpool, on Wednesday, June 28th. Seventy-seven members and visitors were present.

*President's Address.*—The President-Elect (Dr. DESMOND) took the chair, and delivered an able and interesting address. In the first place, he welcomed the members to Liverpool, after an interval of five years. He next paid a tribute to the services rendered to science by the medical press; and he especially congratulated the Association on having so excellent a JOURNAL. He then noticed the improvements that had recently been made in the several departments of practice, and referred at length to those relating to the treatment of diseases of women. Dr. Desmond concluded his remarks by drawing attention to the increase in the number of cases of hydrophobia which had taken place during the last year, no fewer than seven cases having occurred in Liverpool during the past six months; and he especially commended the study of this terrible disease to the profession generally.

*Report of Council.*—The following report was read. Your Council, in presenting their annual report, desire to express the satisfaction they feel in again meeting the members of the Lancashire and Cheshire Branch in Liverpool. Since the last anniversary meeting, in Preston, a subject which has occupied much of the attention of the profession has been the Medical Acts Amendment Bill, introduced by the present Government during the last Parliamentary session. This Bill was thoroughly discussed by your Branch, as well as by the Association generally; and though it presented certain advantages, yet it in no way provided for the direct representation of the general body of practitioners upon the Medical Council. The Association being pledged to the principle of direct representation, could not pursue any other course than that of strenuously opposing a measure which failed to recognise so important a feature in medical legislation. The result of the opposition on the part of the Association was the abandonment of the Bill. Your Council have to announce that your President (Dr. Desmond) has again consented to represent your Branch on the Parliamentary Committee of the parent Association. Your Council have much pleasure in congratulating the members on the increasing prosperity of the Branch. At the beginning of the year, a number of addresses were sent round to the members of the profession resident in Lancashire and Cheshire, in which the objects of the Association were stated. The result has been highly satisfactory, no fewer than seventy-two new members having joined the Branch since the last annual meeting. The number of members lost during the past year from various causes amount to twenty, thus leaving at the present 348 members—a number considerably greater than in any previous year.

Your Council have to regret the loss by death during the past year of several old and valued members of the Association; amongst these may be mentioned the names of Mr. Mallett, of Bolton, a former President of the Branch, and Mr. Daglish, of Wigan, who for many years took an active interest in all that related to the welfare of the Association. (The Report then alluded to the vacancies in the Council, and to the appointment of Representatives of the Branch.)

Dr. Simpson having retired from the local secretaryship at Manchester, your Council have appointed Mr. S. M. Bradley as his successor. The financial statement is in the hands of the meeting. Your Council have pleasure in stating that they have received an invitation to hold the next annual meeting in Manchester, and that a resolution to that effect will be proposed to the meeting.

Mr. GALTHERIE moved that the Report of the Council be adopted. This was seconded by Dr. C. E. LISTER, and unanimously carried.

*Vote of Thanks.*—Mr. MATHER moved that a vote of thanks be given to the late President (Dr. Spencer), the Vice-Presidents, Honorary Secretaries, and other members of Council. This was seconded by Mr. C. B. WILSON, and unanimously carried.

In acknowledging the compliment on behalf of himself and the other office-bearers, Dr. SPENCER expressed regret that, by reason of the late arrival of his train, he was prevented from introducing his successor. He felt sure that the Branch had exercised a wise discretion in selecting Dr. Desmond as their President for the ensuing year.

*Next Annual Meeting: Officers and Council.*—It was proposed by Dr. WILKINSON that the next annual meeting be held in Manchester, and that T. Mellor, Esq., be appointed President-elect; and that Dr. John Cameron and Dr. Ransome be appointed Vice-President-elect. This was seconded by Dr. E. WATERS (Chester), and unanimously carried. Eight gentlemen, whose names are distinguished by asterisks in the following list, were then elected by ballot to fill up the vacancies in the Council, which is now composed of the following twenty members:—E. Bowen, M.D.; J. Cameron, M.D.; \*S. Crompton, M.D.; \*E. D. De Vitre, M.D.; T. Davies-Colley, M.D.; L. E. Desmond, M.D.; \*W. H. Fitzpatrick, M.D.; \*N. S. Glazebrook, Esq.; John Harrison, Esq.; Thomas Howitt, Esq.; \*C. Johnson, Esq.; J. P. Langshaw, Esq.; \*C. E. Lyster, M.D.; W. McEwen, M.D.; \*W. McCheane, Esq.; \*J. McNaught, M.D.; J. E. Morgan, M.D.; D. W. Parsons, L.R.C.P.; A. Ransome, M.D.; J. Thorburn, M.D.

*Representatives in the General Council.*—Mr. HIGGINSON moved the next resolution, which was seconded by Mr. BAILEY, and carried: "That the following gentlemen be elected representatives of the Branch in the General Council:—T. Davies-Colley, M.D.; L. E. Desmond, M.D.; W. Hall, L.R.C.P.; W. Howitt, Esq.; D. W. Parsons, L.R.C.P.; H. Simpson, M.D.; T. Mellor, Esq.; G. W. Mould, Esq.; Wm. Roberts, M.D.; T. L. Rogers, M.D.; L. Spencer, M.D.; G. Southam, Esq.; A. B. Steele, L.K.Q.C.P.; J. Vose, M.D.; E. Waters, M.D.; A. T. H. Waters, M.D.; M. A. E. Wilkinson, M.D.; The Honorary Secretary *ex officio*."

*New Member.*—Dr. Howsin, of Newton, was elected a Member of this Branch.

*Papers and Cases.*—The following communications were then made.

1. Dr. NEVINS narrated a case where long continued Cerebral Pain had been removed by operating upon an External Squint.

2. Dr. HADDON read the notes of a case of Typhoid Fever with a Rare Form of Eruption; and also a case of Meningitis, with diagrams of the pulse-rate and temperature.

3. Dr. C. E. LYSER exhibited the Pneumatic Aspirator, and referred to cases where he had used it with great advantage.

4. Mr. HIGGINSON exhibited his Transfusion Instrument, and pointed out the several advantages attending its use. He had recently had another successful case.

5. Dr. ROBINSON remarked on the great advantage which he had seen follow from the Diffusion of the Watery Vapour of Carbolic Acid through the air of an apartment in cases such as scarlatina maligna, putrid sore throat, and affections attended with foetid expectoration. He exhibited a kettle with a long spout, by which the diffusion was readily and most conveniently effected.

6. Mr. BICKERSTETH exhibited a very large Tumour, which he had recently removed from the Scrotum, and also a Tumour of considerable size which he had removed from the side of the Pharynx by enucleation. In both cases, the results were highly satisfactory; the patients were introduced in order that the members might have an opportunity of examining them. Both cases were well illustrated by photographs and sketches taken before and after operation.

7. Dr. BEALES showed a portion of the Stomach of a youth in which was a Perforating Ulcer. The patient died fourteen hours after the first symptom. Dr. Beales also showed a portion of the rectum, measuring four to five inches, which had sloughed away. The patient was sixty-two years age, and was still under treatment.

8. Dr. GLYNN exhibited and explained his form of Self-illuminating Ophthalmoscope. He demonstrated on a dog the great facility which it afforded for examining the eye in different positions.

9. Mr. T. SHADFORD WALKER made some remarks on the Treatment of Deafness.

*Votes of Thanks* were passed to the readers of papers and exhibitors; to the President and Council of the Liverpool Medical Institution, for the use of the building; and to the President (Dr. Desmond).

*The Dinner* was held, at half-past Four o'Clock, at the Adelphi Hotel, under the Presidency of Dr. Desmond. Sixty-eight members and visitors were present.

## SPECIAL CORRESPONDENCE.

### VIENNA.

[FROM A SPECIAL CORRESPONDENT.]

*Case of Retained Menstrual Fluid.*—The girl, to whom I referred in my letter of May 7th, lived fifteen days after the operation, which was supposed at the time to have been a puncture of the uterus, which, however, it was not. The first abnormality found was atresia vaginae at the vulva; this I did not mention before, as I was not then aware of it. On cutting through the imperforate vulva, Billroth found higher up in the vagina another obstruction, which he took for an imperforate uterine neck. At the *post mortem* examination, however, a dissection showed that a second vaginal atresia existed about the middle of the canal, and that the neck of the uterus was normal. In addition to dilatation of the uterus itself, there were dilatation, contortion, and great thinning of the right Fallopian tube, which, indeed, had burst after the operation, so that a quantity of the confined blood had escaped into the peritoneum. There was general peritonitis with adhesion of the intestines by means of inflammatory flakes; and, besides this, retro-peritoneal abscess.

*Galvano-caustic Polypus-snare.*—This is a very neat instrument, and consists of a combination of the ordinary polypus-snare with the galvanic cautery. A thick platinum wire is used for the snare, and is capable of being made red-hot by a galvanic current, the handle of the instrument receiving the poles of a battery, contact being made and broken at will by moving an appropriate slide. With this instrument Billroth has lately removed part of a sarcoma from the posterior nares, a melano-sarcoma from the rectum, and another tumour from the fauces. He first included the neck of each tumour in the loop of the snare, tightening the wire up by turning the screw-handle until the tumour was just grasped. Contact was now made, and a gentle turn of the handle once more drew the hot wire through, the tumours coming away painlessly, and in two cases quite bloodlessly. Amputation of the penis, in a case of epithelioma of the organ, was also done by means of the same instrument. In this case no preliminary arrest of the blood-flow into the penis was made, and no blood was lost in the operation (May 16th). On June 9th, a second operation was done—that of slitting the urethra and sewing its edges to the skin around.

*Couch for Bandaging.*—Those who are in the habit of putting on starched or gypsum bandages around the thigh and pelvis, and who know what a nuisance it is, when they come to the "spica" turns round the hip, to have to depend on assistants who, when the signal to lift is given, either do it at the wrong time, or at least have their hands and arms in the way—can fully appreciate the comfort of the couch I am about to describe. It consists simply of a board as wide as, and shorter than, an ordinary sofa, and on which slides a shallow box holding a mattress; this box and mattress are not quite as long as a man's body, and lie towards one end of the board; at the other end of the board is an upright rod of iron, with a flat horizontal ledge on one side, and covered with sheet India-rubber. When a patient is to have his hip put up in a gypsum bandage, his back and shoulders are laid on the mattress (the whole concern being previously put on the operating-table), and his sacrum on the iron ledge, the upright part of the iron lying against the perineum. The assistants have simply to hold the lower limbs in proper position, while the pelvis is quite free over and under for bandaging.

a. Fundamental board, on which slides

b. Box holding mattress and pillow; to be adjusted as near as required to

c. Upright iron rod, sliding in a socket up and down, fixed at requisite height; its part, d, is covered with sheet India-rubber, or anything soft, and goes between the patient's thighs. The horizontal portion is flattened out.

*Osseous Ankylosis of Hip following Coxitis.*—Here the right thigh was flexed at about a right angle with the pelvis in a boy about fifteen

years old. Chloroform was given till the boy was completely narcotised, and then, after repeated attempts and with much difficulty, Billroth extended the limb by breaking the neck of the femur. The crack of the bone was distinctly heard over the theatre. The boy was then put upon the couch just described, and, while still under chloroform, the limb was put up in a gypsum bandage in the extended position. The method of applying gypsum bandages in Billroth's clinic is a very excellent one, and will be found fully described in a former volume of the JOURNAL (April 10th, 1869) by your correspondent of that time.

**Medullary Lymphomata.**—A man, aged 30 or 35, now lies in the hospital with two large tumours on the left side of the neck, each about the size of two fists. They are malignant lymphomata according to Billroth, who says that the structure of these growths is identical with that of the innocent lymphomata, the difference lying in the greater rapidity of growth, greater size, and as yet utter incurability of those in question, which recur if cut out, and hitherto have not yielded to drugs.

## REPORTS OF SOCIETIES.

### CLINICAL SOCIETY OF LONDON.

FRIDAY, MAY 26TH, 1871.

W. W. GULL, M.D., D.C.L., President, in the Chair.

DR. MEADOWS related a case of Acute Disease of the Hip-joint following the introduction of a Tangle-Tent into the Uterus. The patient, aged 31, had been married ten years, was sterile, and suffered from dysmenorrhœa. The cervix uteri was dilated with tangle-tents; and after several had been applied she was seized with severe pain in the left hip-joint, and she then came under Dr. Meadows's care for some supposed pelvic inflammation. It was, however, a case of acute inflammation of the hip-joint, which rapidly suppurated, and ended in the course of a few weeks in the destruction of the joint and the death of the patient. On *post mortem* examination, no cellulitis or inflammation of any kind was discoverable about the uterus or its appendages, but an enormous abscess had completely destroyed the hip-joint and parts adjacent. There was no indication whatever of any mischief having been done to the uterus itself.—MR. COOPER FORSTER believed it was one of the many cases in which pyæmia occurred rapidly, consequent upon abrasion of mucous membrane, and that nothing else could account for so speedy a destruction of cartilage.—DR. BUZZARD asked whether other joints were examined, as the presence of suppuration in more than one would be conclusive as to the pyæmic character of the affection.—MR. LAWSON observed that a very considerable amount of difficulty sometimes occurred in the withdrawal of tangle-tents, because the tent was much confined by the neck of the uterus, and greatly dilated beyond.—MR. WARRINGTON HAWARD, supporting the pyæmia hypothesis, mentioned that, of a hundred and thirty cases of joint-disease collected by him, evidences of tubercular disease existed in nine, and of scrofula in seventeen only, and that the temperature in Dr. Meadows's case negated any idea that tubercle had influenced the disease.—MR. BRUDENELL CARTER inquired if any abrasion were necessary, and said that he had been informed of three instances in which pyæmia had been consequent upon simple gonorrhœa.—MR. LAWSON TAIT related brief particulars of a fatal case in which these tents had been used, and expressed a belief that they were dangerous.—THE PRESIDENT thought that Mr. Carter's remarks as to gonorrhœa were important. He recollected a case of gonorrhœa in which suppuration of the veins of the spinal cord took place.—DR. MEADOWS, in reply, said that a distinct double osseous abscess. No other joints were examined. He disagreed with the observations of Mr. Tait, as to the danger incurred by the use of tangle-tents, unless they went too far in.

MR. HOUTHOUSE read a paper on the Treatment of Temporarily Irreducible Hernia. He entirely concurred in the doctrine that there was no remedy for an inevitably strangulated hernia but the surgeon's knife, and related several cases to show that many herniæ, though accompanied by symptoms of strangulation, were not inevitably strangulated, and might be reduced by opium; and this drug had the further merit of being a very delicate and safe test of the necessity or otherwise of an operation—a single dose was sufficient to determine the point. If it were rejected, the patient should be immediately put under the influence of chloroform, a gentle attempt made to reduce the hernia by the taxis, and, this failing, herniotomy performed; on the other hand, if the opium were retained the symptoms would abate, the rupture would go back, and no operation would be necessary.—MR. COOPER FORSTER commented on the great range for discussion opened out by these notes.

He denounced energetically the opium and other temporising plans of treatment, and maintained that if a more speedy recourse than is usual were had to the knife, the mortality in these cases would be reduced at least 80 per cent.—MR. TAIT urged the employment of hypodermic injections of morphia, in conjunction with chloroform and the taxis.

DR. ANSTIE read a case of Neuralgia in all the three branches of the fifth nerve, reinduced in a person who had suffered from it before, by the intercurrent of constitutional syphilis. There were complete anæsthesia of the affected side of the face, exactly reaching the mesial line, complete paralysis of the third and sixth nerves, loss of taste in the neuralgic half of the tongue, loss of smell on both sides, and spasms of the masseter muscle. The neuralgia and the anæsthesia were rapidly cured by large doses of iodide of potassium; and not only the function of taste, but also that of smell, recovered *exactly pari passu* with the recovery of the fifth nerve. The ocular paralysis remained. The spasm of the masseter disappeared simultaneously with the neuralgia and anæsthesia. The woman, who was married and had three very healthy children, and had never aborted, was probably only syphilised about one year ago, and many years after the first attack of neuralgia, which partook of the character of migraine.—DR. HUGHLINGS JACKSON remarked on the great interest of Dr. Anstie's observation on the occasional coincidence of facial neuralgia with partial anæsthesia of the painful region. He (Dr. Jackson) supposed that persistent, although partial, loss of feeling must depend on destruction of nerve-fibres; and neuralgia especially, if it were paroxysmal, on discharges of ganglion-cells connected with intact fibres. An analogous fact was the not unfrequent occurrence of convulsions in muscles which were imperfectly paralysed. Dr. Jackson asked as to the condition of the masseter and temporal muscles. He suggested that the loss of smell might depend on an olfactory neuritis analogous to optic neuritis; and, as bearing on this, asked if an ophthalmoscopic examination had been made. It was certain that severe optic neuritis might exist when sight was unaffected. In some cases of cerebral disease, there was loss of smell with amaurosis from optic neuritis.—MR. LAWSON said that it was rare to find paralysis of the ocular muscle occurring so soon after syphilis, several years usually intervening.—DR. BUZZARD thought that, as there was evidence of lesion of the third, fifth, sixth, and probably the fourth, nerves of one side, it was easier to imagine that the syphilitic effusion (if such it were) involved also the first pair of nerves than that lesion of one only of the fifth pair caused loss of smell on both sides.—MR. CARTER had seen Dr. Anstie's patient once; he found the ptosis complete; the superior oblique muscles were, however, intact.—MR. TAIT asked if any affection of the pupil existed.—MR. FORSTER hoped that Dr. Anstie would not add that disease to the long list of results already attributed to syphilis.—DR. ANSTIE said that the case was most undoubtedly syphilitic. As regarded the loss of smell, he thought that, supposing it to depend on the lesion of the fifth, there was no impossibility that it should occur on both sides. Although the neuralgia was unilateral, many equally singular anomalies occurred among the complications of neuralgia. He had not examined the eye with the ophthalmoscope, as it seemed that the function of the retina was perfect: had he known the facts observed by Dr. Jackson, he would have made the examination.

DR. HUGHLINGS JACKSON gave particulars of a case of Right Hemiplegia, with loss of speech (nearly complete aphasia), which had been investigated by himself and Mr. Stephen Mackenzie. The hemiplegia, with the affection of speech, pointed to some kind of disease of, and of the convolutions near to, the corpus striatum. From the manner of onset, and from other circumstances, he inferred that there was softening from thrombosis; and as the patient presented well-marked external signs of syphilis, he supposed the softening depended on thrombosis of an artery which was diseased from syphilis. He did not speak of atheroma (endarteritis), which was believed by some to be an occasional result of syphilis, but of what may be called nodes of arteries (gummatous affections). He alluded to the observations of Bristowe (Pathological Society's Transactions, 1859) on thrombosis of cerebral arteries from syphilis, and those of Wilks (Guy's Hospital Reports, 1863) and Moxon (*ibid.*, 1867-8) on cases of syphilitic disease of cerebral arteries; and referred to several cases published by himself (*The Lancet*, 1866, and *London Hospital Reports*, vol. iv). He urged the great importance of recognising that many "syphilitic affections" of the nervous system are really dependent but very indirectly on syphilitic changes, and especially that in some cases of "syphilitic hemiplegia" the pathological condition of the nerve-centre on which the palsy directly depends is like that produced by embolism. We quickly cure recent palsies of cranial nerves from the direct action of syphilis on the nerve-bundles; but to cure certain cases of syphilitic hemiplegia we have to do more than to treat syphilis, and our treatment of these cases is often unsuccessful.—THE PRESIDENT considered the case very important. Iodide of potassium would cure the syphilis, but not its effects on surrounding

tissues.—Mr. CARTER related an instance that had come under his own observation, in which the patient had been treated for syphilis with iodide of potassium with benefit; but hemiplegia supervened, and from that time the drug did no good.—Dr. ANSTIE had prescribed half-drachm doses of iodide of potassium for neuralgia with particularly good results.

Mr. CALLENDER then read a note on a plan of Reducing Old Dislocation at the Shoulder. The method, illustrated by the history of a case, consisted in raising the elbow of the dislocated limb across the chest nearly to the level of the interclavicular notch, forcing the raised arm outwards, rotating the arm in so doing, and lastly, whilst still rotating, somewhat depressing it. Practically, this plan of manipulation avoided all risk of injuring the great vessels in the axilla, as all pressure upon them was done away with.

## CORRESPONDENCE.

### THE ANNUAL MEETING.

SIR,—In the circular just issued to members of the medical profession who have not yet joined the Association, I have noticed an error in regard to the excursion into Cornwall connected with the approaching meeting at Plymouth, which should be corrected at once, as the arrangements of the busy practitioner for his too brief holiday must be made some time beforehand. The days appointed for the excursion of the Royal Institution of Cornwall are Monday and Tuesday, the 14th and 15th of August; not the preceding Thursday and Friday, as intimated in the circular, which is so far a reprint of the notice in the JOURNAL of January 7th. The time now fixed is that originally contemplated; it was altered at the desire of our Plymouth friends, so as to fall within the limits of the meeting there; but the Committee of Council having subsequently—very judiciously, as I think—requested that no distant excursion should be arranged for the Thursday on which the dinner of the Association is to take place, the days first named for a visit to the far west were recurred to. In fact, as Penzance, the rendezvous of the excursionist, is eighty miles from Plymouth, and as the leading objects of interest can barely be seen in two days, it is clear that an attempt to dovetail this expedition with the business of the Plymouth Meeting could only tend to interference with the success of both. It is to be hoped that many of our members may be able to indulge themselves with an extension of their holiday trip, from Plymouth into these remote parts of the country; and the excursion, of which full particulars will soon be issued, will enable them to visit the points of greatest interest in a very agreeable way.

I am, etc., C. BARHAM.

Truro, July 11th, 1871.

### MIDWIFERY AND THE MEDICAL COUNCIL.

SIR,—Will you pardon my intruding on your space in asking for information. Are we to understand that the Medical Council by their recent decision consider that midwifery proper requires no more instruction than botany, and that the diseases of women and children require none at all?

I am, etc., J. BRAXTON HICKS.

9, St. Thomas's Street, S.E.

### PROFESSOR HAUGHTON'S TELEOLOGY.

SIR,—It has been on my mind some time to write a short inquiry upon one point at least of Professor Haughton's brilliant discourses recently published. What Dr. Haughton says, is said so effectively that it seems as if it must be right—facts could not resist the charming of so eloquent an interpreter, and perhaps they follow his piping as less rigid things once followed Amphion. One very favourite burden of his song was this. Seeing, then, the marvellous adaptation of machinery to work done, and, what is more, the marvellous attainments of this on principles of least action, how can we suppose this machinery to have been gradually evolved? Here is nothing tentative, but here, rather, are works struck out neatly and perfectly at a blow, as watchworks are now struck from a die. And then follows much vigorous teleological argument of the same kind. Surely this is a triumph of sheer boldness; and for my poor part, conscious as I was that the eminent professor could not err, in logic at any rate, I read these passages over several times, in patient desire to arrive at their signification. But I have failed; and as others of your readers may be struggling with like doubts, may I venture to point out that in our humble judgment the argument seems to have precisely the opposite force. An evolutionist will say that realisation of least action may or may not be compatible with teleological schemes; but for his hypothesis it is not only favourable, but

absolutely essential. Any margin of machinery over and above that which is necessary would be destructive evidence against him, as it would be wholly uncaused—which is impossible. On the other hand, the teleologist should rejoice in any margin of power; for to it he would point as a provision which could not have been called forth by the average of circumstances, but must have been added as a safeguard by a prescient Creator. It is necessary for a Darwinian to prove that Nature "runs it fine"; but to a teleologist it ought to be not only unnecessary, but even rather disappointing. "But", it may be said by the professor, "there might have been a want of equation on the other side. I do not rely upon the absence of excessive provision for work, but upon the presence of that which is always sufficient; I assert that the exquisite balance which I have demonstrated in a few of the highest and perfect animals, and in the most effective parts of these, is also present in every organ of all animals." This is a hardy optimism, however, to which the lecturer will, I think, scarcely commit himself.

Leeds, July 12th, 1871. I am, etc., T. CLIFFORD ALLBUTT.

## OBITUARY.

### SAMUEL M. HEWITT, L.K.Q.C.P., OF DUBLIN.

ALTHOUGH Dr. Hewitt, whose death took place lately, had not reached the age of twenty-five, he had acquired a very leading position amongst the junior physicians of Dublin. Commencing as demonstrator of anatomy, and private teacher in the school of the College of Surgeons, he became so popular that his election to the physiciancy of the City of Dublin Hospital was unopposed. In the fever-wards of this institution his devotion to the sick poor was most exemplary, and in them he contracted the contagion of typhus, which quickly resulted fatally. The May number of the *Dublin Quarterly Journal of Medicine* contains a most able and suggestive paper on "The Present State of Therapeutics", by Dr. Hewitt. His interment was attended by all his colleagues, and several other eminent medical men; and over one hundred students walked in the procession.

### ARTHUR WILLIAM DUMVILLE, F.R.C.S., MANCHESTER.

THE profession in Manchester has sustained a heavy loss in the death of Mr. A. W. Dumville, who died on Saturday, July 8th, 1871, at the age of 52, deeply mourned by a wide circle of friends and patients, and by his colleagues at the hospital. Both in his public career as surgeon to the Manchester Infirmary, and (for many years) as lecturer on surgery at the School of Medicine, and in private life, he succeeded in gaining the confidence and affection of all with whom he came in contact; indeed, it is the simple language of truth to say that he died as had lived, without a single foe. His care and ability as a clinical teacher made him deservedly popular among the students, who will for a long time to come sincerely deplore his loss.

Mr. Dumville was not only gifted as an instructor, but was possessed of rare tactical skill as a surgeon. Among many other proofs of his manual ability, may be cited how brilliantly he was wont to perform Syme's operation of external urethrotomy without a guide: it is not over-praise, indeed, to affirm that no living surgeon surpassed, few could equal, the dexterity with which he performed this operation.

Mr. Dumville wrote but little, and it is therefore possible that, beyond his own city, it may be little known how skilful and judicious a surgeon, how accomplished a man, how kind a friend, how true a gentleman, has left our ranks.

### ROBERT DUNDAS, M.D.

ON the 25th of June the medical profession lost a distinguished member, and his numerous friends a respected and beloved companion, in the death of Dr. Robert Dundas. Born in Ireland towards the end of the last century, he entered the medical service of the army at an early age. He served in the Peninsula, and was present at the siege of New Orleans in 1815. He subsequently settled at Bahia, in Brazil, where he had the medical superintendence of the British Hospital for twenty-three years with great credit to himself and benefit to others. His health giving way, he resigned his hospital appointment and practice, and returned to Europe with ample means, the product of his skill and industry. He

was, however, much too active minded to accept the leisure so well earned by twenty-eight years' service in tropical climates; and as soon as his health began to recover he settled in practice in Liverpool. Here he was appointed physician to the Northern Hospital, and again did good work for several years. In 1852 he published, under the title of *Sketches of Brazil*, a work in which he advocated strenuously the doctrine that intermittent fever is not necessarily the result of so-called malaria, but may be generated in the human economy by the electrical, thermometric and morbid hygienic conditions, quite apart from the action of marsh miasmatic. He also brought forward a considerable mass of evidence to prove the possibility of arresting the course of continued fever by quinine. In 1854 Dr. Dundas gave up his Liverpool position, and settled in London at Gloucester Place, where he spent the last years of an eventful life. He died of exhaustion following a severe and continued attack of sciatica, in his eightieth year. He was an upright, conscientious, intellectual man, of firm will and unflinching resolve. He combined with a certain sternness of character so much warmth of affection and sympathy for those whom he esteemed and loved, that he exercised over them great influence.

## MEDICAL NEWS.

**APOTHECARIES' HALL.**—The following gentleman passed his examination in the science and practice of medicine, and received his certificate to practise, on Thursday, July 6th, 1871.

Bowes, John Ireland, Elham, Canterbury  
Pope, Harry Campbell, Tring, Herts  
Willocks, Isaac, West Looe, Cornwall  
Williams, Ralph Worthington, Hurst, near Ashton-under-Lyne

The following gentlemen also on the same day passed their first professional examination.

Mahomet, F. H. A. A., Guy's Hospital  
Webb, William Edward, King's College

As an Assistant in compounding and dispensing medicines.

Nutt, William Anthony, Barnstable, Devon

**UNIVERSITY OF DUBLIN.**—At the Summer Commencement, held on Wednesday, June 28th, in the Examination Hall of Trinity College, the following Licenses and Degrees in Medicine and Surgery were conferred by the Right Honourable Sir Joseph Napier, Bart., LL.D., Vice-Chancellor of the University.

*Licentiatum in Medicina:*—Thomas Johannes Browne, and Ricardus Dancer Purefoy.

*Licentiatum in Chirurgia:*—Ricardus Dancer Purefoy.

*Baccalarii in Medicina:*—Jacobus Armstrong, Otway Petrus Browne, Edvardus Mariere Courtenay, Thomas Drapes, Andreas Franciscus Dolson, Christophorus Elliott, Thomas Sargent Floyd, Georgius Gibson, David Kennedy, Patricius Johannes Molony, Thomas Hamilton Moorhead, Johannes Morgan, Jacobus O'Connor, Ricardus Henricus Quill, Johannes Godfredus Rogers, Henricus Johannes Twendy, Johannes Waugh, Gulielmus Marcus Whittaker, and Thomas Blair Worthington.

*Magistri in Chirurgia:*—Jacobus Armstrong, Otway Petrus Browne, Edvardus Mariere Courtenay, Franciscus Georgius Mayberry, Patricius Johannes Molony, Ricardus Henricus Quill, Johannes Godfredus Rogers, Johannes Waugh, and Thomas Blair Worthington.

*Doctores in Medicina:*—Edvardus Wolfenden Collins, Johannes Gulielmus Moore (step. con.), Johannes Morgan, Johannes Todhunter, Arthurus Wellesley Tomlin, and Geraldus Franciscus Vee.

## MEDICAL VACANCIES.

The following vacancies are announced:—

ARDWICK AND ANCOATS DISPENSARY, Manchester—Consulting Surgeon.  
BLACKBURN AND EAST LANCASHIRE INFIRMARY—House-Surgeon.  
BEECHNOCK INFIRMARY—House-Surgeon.  
BRISTOL GENERAL HOSPITAL—Consulting Surgeon.  
BRISTOL DISPENSARY—Resident Dispenser.  
BURY LANCASHIRE DISPENSARY—Resident Medical Officer.  
CARMICHAEL SCHOOL OF MEDICINE, Dublin—Lecturer on Anatomy and Physiology.  
CITY OF DUBLIN HOSPITAL—Physician.  
DERBYSHIRE GENERAL INFIRMARY, Derby—Resident Assistant House-Surgeon, and General Surgeon; Senior Resident Dispenser.  
EVELINA HOSPITAL—House-Surgeon.  
FABINGDON UNION, Essex—Medical Officer and Public Vaccinator for the Parish of Fabingdon.  
GENERAL HOSPITAL AND DISPENSARY FOR SICK CHILDREN, Bridge Street, Manchester—Resident Medical Officer.  
HOSPITAL FOR SICK CHILDREN, Great Ormond Street, Assistant Physician.  
HUDDERSFIELD INFIRMARY—House-Surgeon.  
HUDDERSFIELD AND UPPER ABERCROMBIE INFIRMARY—Physician.  
INFIRMARY FOR CONSUMPTION AND DISEASES OF THE CHEST, Margaret Street, Cambridge Square, Victoria Park, London.  
INFIRMARY FOR EPILEPSY AND PARALYSIS, Currier Street, Portman Square—Physician.  
KILKEL UNION, co. Down—Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the Second Division of the Kilkeel Dispensary District.

LEEDS PUBLIC DISPENSARY—Junior Resident Medical Officer.

LEWES UNION, Sussex—Medical Officer for the Lower District and the Workhouse.

LOCHGORLHEAD AND KILMORICH, Argyleshire—Parochial Medical Officer.

LOUDOUN, Ayrshire—Medical Officer and Public Vaccinator.

LOYAL EARL OF LONSDALE LODGE OF ODD FELLOWS, Bampton, Cumberland—Medical Attendant.

MANCHESTER ROYAL INFIRMARY—Surgeon.

MATER MISERICORDIÆ HOSPITAL, Dublin—Physician.

MIDDLESEX HOSPITAL MEDICAL COLLEGE—Lecturer on Physiology, including Practical Physiology.

NORTH DUBLIN UNION—Medical Officer, North City Dispensary District.

NORTH-WEST LONDON FREE DISPENSARY FOR SICK CHILDREN, Bell Street, Edgware Road—Physician.

RATHDOWN UNION, co. Dublin—Medical Officer for First Division of the Kingstown Dispensary District.

ROYAL ORTHOPÆDIC HOSPITAL—Resident House-Surgeon & Apothecary.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL—Teacher of Physiological Chemistry.

ST. THOMAS'S HOSPITAL—Resident Assistant-Physician; Assistant-Surgeon.

SUFFOLK GENERAL HOSPITAL, Bury St. Edmunds—Physician.

WARWICK COUNTY LUNATIC ASYLUM, Hatton—Assistant Medical Officer.

WEST LONDON HOSPITAL—Junior Physician; House-Surgeon.

WESTMINSTER HOSPITAL—Assistant-Surgeon.

WIRRAL HOSPITAL AND DISPENSARY FOR SICK CHILDREN, Birkhead—Honorary Medical Officer.

## MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

\*BLOXAM, J. A., Esq., appointed Junior Surgeon to the West London Hospital; CAIRD, Thomas Wilson, Esq., elected Surgeon to the Devon and Exeter Hospital, in the room of \*A. Kempe, Esq., resigned.

CONNOLLY, Andrew E., L.K.Q.C.P.Irel., appointed Medical Officer for the Cahircorlish Dispensary District of the Limerick Union.

HARTIGAN, Jeremiah T., L.K.Q.C.P.Irel., appointed Medical Officer for the Croom Dispensary District and the Workhouse of the Croom Union, co. Limerick.

HAY, Robert, L.F.P.S.Glasg., appointed Medical Officer for the parish of North Bute, Buteshire.

\*JONES, Talfourd, M.B.Lond., appointed Physician to the Brecon County and Borough General Infirmary, vice Prestwood Lucas, M.D., deceased.

\*LANDDOWN, F. Poole, Esq., re-elected Surgeon to the Bristol General Hospital.

McFADYEN, C., M.B., elected Medical Officer for the parish of Straith, Isle of Skye.

PRESTON, Eyre Frederick, L.K.Q.C.P.Irel., appointed Medical Officer to the Workhouse and Fever Infirmary of the Kilkeel Union, co. Down.

VERNON, B. J., Esq., appointed Ophthalmic Surgeon to the West London Hospital.

WATSON, Albert, L.K.Q.C.P.Irel., appointed Medical Officer for the Lucan Dispensary District of the Celbridge Union, co. Kildare.

\*WILTSHIRE, Alfred, M.D., appointed Physician for the Diseases of Women to the West London Hospital.

## BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication.

### BIRTHS.

GRIFFITH.—On July 3rd, at Portmadoc, Carnarvonshire, North Wales, the wife of \*Samuel Griffith, M.D., of a daughter.

LONG.—On July 3rd, at Cromer, Norfolk, the wife of \*Mark Long, M.D., of Canning Town, Essex, of a daughter.

### DEATHS.

BENNETT, W. R. H., Esq., Surgeon, at Shaftesbury, aged 38, on June 28th.

\*HESTER, James, M.D., son of J. T. Hester, Esq., late of Oxford, at Wanganatta, Australia, on May 1st.

LANDDOWN, Joseph G., Esq., late Surgeon to the Bristol General Hospital, at Bristol, aged 67, on July 6th.

MAY, Willoughby, Esq., Surgeon, at Teignmouth, aged 31, on July 5th.

\*TANNER, Thomas H., M.D., of Henrietta Street, Cavendish Square, at Brighton, aged 46, on July 7th.

**THE MEDICAL COUNCIL AT CAMBRIDGE.**—On Saturday last, Dr. Paget, President of the Medical Council, invited the whole of the Council (twenty-four in number) to accompany him to Cambridge, on its rising at four o'clock. With few and unavoidable exceptions, the invitation was cordially accepted; and the Council, who always terminate their proceedings at 4 P.M. on Saturdays, proceeded by the 5 P.M. train to Cambridge, where a sumptuous dinner awaited them in the hall of Caius, and a distinguished party assembled to meet them. The next day, they met at Dr. Paget's house to breakfast, and thereafter dispersed themselves to various churches, as taste or inclination prompted. In Cambridge, there is an ample choice, for places of public worship are provided for nearly all religious bodies of any note. On that day, besides a number who reassembled to dinner at Dr. Paget's, several partook of the famed hospitality of the Colleges, Mr. Porter of Peterhouse and others having large parties. Leaving Cambridge with great regret, and deeply impressed with the magnificent hospitality of their President, and with pleasant recollections of the architectural and scenic beauties which commingle in that beautiful town, the various guests left by early trains, and resumed and concluded their duties in London on Monday.

## OPERATION DAYS AT THE HOSPITALS.

MONDAY .....Metropolitan Free, 2 P.M.—St. Mark's, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.

TUESDAY .....Guy's, 1.30 P.M.—Westminster, 2 P.M.—National Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.

WEDNESDAY..St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.

THURSDAY ...St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.

FRIDAY .....Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic Hospital, 2 P.M.

SATURDAY ...St. Thomas's, 9.30 A.M.—St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Lock (Clinical Demonstrations and Operations), 1 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—East London Hospital for Children, 2 P.M.—Hospital for Women, 9.30 A.M.

## NOTICES TO CORRESPONDENTS.

ALL Letters and Communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen Street, Lincoln's Inn Fields, W.C.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

TO PURCHASERS.—To insure attention, it is requested that all orders sent to the Office for extra copies of the JOURNAL, be accompanied with halfpenny stamps for the amount.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

## OUT-PATIENTS' HOSPITAL REFORM.

SIR,—Will you allow me to report in your columns that, at a meeting of the Committee held last week, my balance-sheet was audited, and the accounts examined, from which it appeared that the total receipts amounted to £49:18:4, and the total expenditure to £49:4:10, leaving a balance in hand of 13s. 6d.; against which there are some petty expenses of about 30s. due to the secretaries.

I will not trouble your readers with any further appeal.

I am, etc., ALFRED MEADOWS, M.D., Honorary Treasurer.  
George Street, Hanover Square, July 1871.

DR. BAKEWELL, North Gate House, Leicester, explains that, although he intended to return to Trinidad when he joined the Association, he has since changed his mind, and now purposes staying permanently in England.

THE papers of Dr. Heaton (Leeds), Dr. Clifford Allbutt (Leeds), Mr. R. H. Meade (Bradford), Mr. Whitehead (Manchester), Mr. Brown (Haverfordwest), Mr. Underhill (Birmingham), Mr. Rigden (Taunton), Dr. Bradbury (Cambridge), Mr. C. F. Maunder (London), Dr. R. Barnes, Mr. John Wood, Dr. Duckworth, Dr. John Ogle, Mr. Jessop (Leeds), Dr. Taylor (Penrith), Dr. Woakes (Luton), and other contributors, are marked for early insertion.

ACCORDING to Dr. C. Kidd on death from chloroform, "the heart is not paralysed," but the right half of the heart is obstructed from apnoea."

## ANÆSTHETICS.

SIR,—In looking over the JOURNAL of May 13th, the article headed "Deaths from Anæsthetics" particularly arrested my attention. It is a subject in which I have always taken a deep interest; and I was among the first in this country who put in use ether as an anæsthetic, after receiving intelligence of its successful employment in Boston, United States. I was then actively engaged as honorary surgeon in the Southern Hospital here; and I, along with my colleagues, continued the use of it, as well as that of chloroform, in every operation for many years, without a single death having occurred to us from these anæsthetic agents. Indeed, up to this time, I have never witnessed a death from the inhaling of ether or chloroform, either in my private or hospital practice, although I have used them freely whenever called upon to do so. My object in this communication is merely, at present, to refer to the following passage in your article: "Is it true that out of all the enormous number of cases in which it (chloroform) has been administered to lying-in women, it has never produced any fatal accident? If so, what is the explanation of such a fact?" In a number of the *Medical Times and Gazette* of 1860, you will find a short letter of mine "On the Prevention of Accidents from the Inhalation of Chloroform." Seeing the fact on record at the time I wrote, that seventy thousand parturient women had had chloroform during their labour without one death occurring among them, I felt it quite confirmatory of the opinion which I had for some time previously held, and which I still hold, that the position of the patient in the bed or on the operating table has everything to do with the immunity from danger in the former case, and with the constantly recurring fatality in the latter. In parturition, as a rule, the woman is placed on her left side, and she inhales the chloroform, with an unmeasured ingress of air, into the lungs, with little or no chance of its being interrupted in any way. The patient undergoing an operation is almost always placed horizontally on his back on the operating table, and inhalations of the chloroform is usually effected by placing a piece of lint, or the corner of a towel sprinkled with chloroform, over the nose and mouth, the apparatus being occasionally lifted to admit air. When the patient is thus rendered insensible, the towel or lint is removed, and respiration may go on, but it not infrequently happens that the tongue, by its weight, falls back, and the epiglottis at its base covers the larynx, and will totally prevent inspiration; so that under this condition, with the air-passages filled with the vapour of chloroform, in two or three minutes the patient would inevitably die suffocated, or in an absolute state of apnoea.

Liverpool, May 31st, 1871.

I am, etc.,

J. PETRIE, M.D.

NOTICES of Births, Marriages, Deaths, and Appointments, intended for insertion in the JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

ACCIPERE DUM LOLET!—The terms of a physician-accoucheur are, of course, cash on delivery. This principle is especially important to those following the "olive" branch of the profession.

THE concurrence of many annual meetings of Branches has brought to the JOURNAL many interesting papers read at those meetings, of which some have appeared in recent numbers, and others will be published in rapid succession.

## TAPE-WORM.

SIR,—Will any of your numerous readers help me in the following case? A lady for the last eighteen months has been suffering from tape-worm. She has tried the male fern, kousso, kamala, and turpentine repeatedly. On each occasion, various lengths have been expelled; but it still continues to be reproduced.  
July 8th, 1871.

I am, etc.,

M.D.

WE are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The New York Medical Gazette, July 8th; The New York Medical Record, June 29th; The Boston Medical and Surgical Journal, June 29th; The Madras Mail, May 1st; The Shield, July 8th; The Philadelphia Medical Times, June 21st; The Philadelphia Medical Independent, June 24th; The Birmingham Morning News, July 10th; The Kentish Express, July 8th; The Cambrian, July 7th; The Southport Visiter, July 7th; The Durham Chronicle, July 7th; The Exeter and Plymouth Gazette, June 7th; The Salopian, July 1st; The Western Daily Mercury, June 6th; The Royal Cornwall Gazette, July 1st; etc.

COMMUNICATIONS, LETTERS, ETC., have been received from:—

Mr. Annandale, Edinburgh; Dr. Alfred Meadows, London; Mr. W. H. Spencer, Preston; Dr. G. F. Elliott, Hull; Dr. C. Radclyffe Hall, Torquay; Messrs. Hammond and Co., London; Mr. T. R. Jessop, Leeds; Mr. J. D. Brown, Haverfordwest; Mr. Andrew Davies, Swansea; Mr. Walter Whitehead, Manchester; Mr. Lawson Tait, Birmingham; Mr. Annington, Cambridge; Dr. J. Milner Fothergill, Harrogate; Dr. Elliott, Carlisle; Mr. B. W. Richardson, Dublin; Our Edinburgh Correspondent; Mr. Harry Leach, Greenwich; Mr. G. W. Mr. P. Bourjeaud begs to

inform the Medical Profession that he has the pleasure of announcing the arrival of his London Establishment, and requests that all orders may be sent to

49, DAVIES STREET,  
BRISTOL, GLOUCESTER,  
LONDON, W.

Caution to the Medical Profession against the numerous spurious imitations.

Oxygenated Water is the

best and most refreshing of all drinks, and is highly recommended by the Medical Profession. It is sold in bottles of 12 and 24 each, and is also sold in bulk. Price 1s. per gallon. London, 1871.

Cadbury's Cocoa Essence,

Registered. Guaranteed a genuine preparation of the finest Cocoa.

The essence of fatty matter which makes cocoa indigestible is easily removed, and the cocoa treated thus will be found to be one of the most nutritious, agreeable, and restorative of drinks. *British Medical Journal*, July 20, 1869.

## GILLON'S ESSENCE OF BEEF,

Or MEAT JUICE, for instantly making Beef Tea for Invalids. Prepared by JOHN GILLON & CO., Preserved Provision Manufacturers, Leith. This valuable article is strongly recommended by Professor CHRISTISON of Edinburgh, and is largely prescribed by the Medical Profession. It is simply the Juice of the best Ox Beef, and it will, without trouble or loss of time, produce Beef Tea of the finest quality and flavour, such as the stomach will retain under sea-sickness, or when every thing else is rejected. It is more economical than Beef Tea prepared in the family, and, as it will keep good for any length of time, no house should be without it.—For its Medical Properties, see Article by Professor Christison of Edinburgh, in the *Monthly Journal of Medicine*, January 1855. (Post free on application.)

Essence of Mutton and Essence of CHICKEN, prepared in exactly the same manner.

Essence of Beef Lozenges.

These Lozenges are made by carefully evaporating the Essence of Beef, as advertised above, to one-sixteenth of its bulk; they are warranted to be the pure Extract of the best Scotch Ox Beef.

RETAIL PRICES.

Essence of Beef { 4 oz. 8 oz. 16 oz. tins.  
Essence of Mutton { 7s. 6d. .. 13s. 6d. .. 26s. 6d. per doz.  
Essence of Chicken 12s. 6d. .. 25s. 6d. .. per doz.  
Essence of Beef Lozenges, 1s. 2d. per box.

GILLON'S

Extractum Carnis (Liebig's)

Process, prepared solely from finest Scotch Ox Beef. Great Strength. Delicate Flavour.

Free from all burnt taste.

Retail Prices—1 oz., 1s. 6d.; 2 oz., 2s. 6d.; 4 oz., 4s. 6d.; 8 oz., 8s. 6d.; 16 oz., 17s. In pots, weight guaranteed.

Special Terms to Hospitals, Infirmarys, and Charities.

WHOLESALE AGENTS.

LONDON—John Bell and Co., 338, Oxford Street, W.; W. Edwards, Old Change; Barclay and Sons, Farringdon Street, E. C.; F. Newbery and Sons, 45, St. Paul's Churchyard; Crosse & Blackwell, Soho Square, W.; and Joseph House, 76, Minories, E.

Sold by all Druggists and Italian Warehousemen.

DINNEFORD'S FLUID MAGNESIA.

Perfect in purity and strength.

"The Fluid Magnesia I obtained from you corresponds precisely with that of the British Pharmacopoeia 1867, and is what the preparation should be."—PROFESSOR RANBYEN. Sold in Gallon and Half-Gallon Jars, for the use of the Profession only, by all Wholesale Druggists, and by the Manufacturers, DINNEFORD & Co., Pharmaceutical Chemists, 172, New Bond St., London.

# LECTURE ON THE TREATMENT OF HIP-JOINT DISEASE.\*

By LEWIS A. SAYRE, M.D.

Surgeon to the Bellevue Hospital, New York; and Lecturer on Clinical Surgery.

I AM much obliged, gentlemen, for the privilege of being able to explain to so distinguished an audience any views I may have upon this particular disease. You have certainly one of the largest fields in this institution for its study that I have ever seen; and I am very happy to see Mr. Marsh carrying out the principle of extension which I consider the proper basis of treatment. The only suggestion I have to make is with regard to the application of this principle in such a manner as to afford the children the benefit of out-door exercise. You can hardly expect me, in half-an-hour's talk, to convey a full idea of my views in regard to the treatment of this disease, its anatomy, pathology, and so forth. I take it for granted that you are perfectly familiar with the anatomy of the joint; and I will spend the short time at my disposal in giving you in a condensed form the views which I hold in regard to treatment. Of course you understand that it is a ball-and-socket-joint, having its ligaments, synovial membrane, the interarticular cartilage or cartilage of incrustation—which, by the way, has very little vitality, but is merely intended as a buffer or cushion to break the concussion; it lives, as it were, by imbibition, upon the little network or tufts of vessels between it and the bone. Cartilage is very much like the barnacles on a ship; it lives by attachment, and by absorption through these little tufts of vessels; and, like all organs vitalised in that way, it easily undergoes disintegration or death. The ligamentum teres, coming from the little fossa at the head of the bone, and being bifurcated and inserted into each side of the notch of the acetabulum, has also a small amount of vitality, one little blood-vessel and nerve running through it; and of course it is liable to be easily injured. I merely mention these things to show that the disease of the joint will occur either in the synovial membrane lining it, or in the ligaments that hold it together, or in the little network of blood-vessels that lie directly under the cartilage of incrustation, between it and the bone. I doubt much if ever the disease commences in the cartilage itself; this subsequently becomes involved in it. The diagnosis whether the disease has commenced in the bone, or rather in the blood-vessels at the extremity of the bone, or in the synovial membrane, or in the ligamentum teres, is sometimes difficult to make out, for the one soon runs into the other.

Taking it for granted that I am speaking, not to medical students, but to medical men who are perfectly familiar with the physiological condition of the joint, I will go at once to the pathological changes that take place.

There is, first, a synovial inflammation, which is always followed by effusion. Then there is a wrench or tear of the ligamentum teres, which is almost always followed by a destructive inflammation of the bones of the joint, particularly if a concussion have been at the same time associated with the wrench or tear. Synovial inflammation is almost always the result of exposure. Skating, racing, jumping, playing, football, and other movements that over-exercise the joint, followed by a sudden exposure and change of temperature, will produce synovial inflammation in the hip-joint as well as any other joint. When boys are wrestling, going through violent gymnastics, twisting their legs in various positions, putting the ligamentum teres upon the stretch will produce a tear—probably not tearing it entirely off, otherwise attention would be called to it, and they would be put under treatment; but generally the smaller the rip the greater the danger, because it is neglected; and it is sometimes months before the disease is seriously developed, and frequently by this time the origin of the difficulty has been forgotten.

A concussion, a blow, a jump from a great height, would cause a pressure upon this little network of blood-vessels which I described as existing between the intra-articular cartilage and the head of the bone; this would produce a "blood-blister," or extravasation of blood at that point, which would be the nidus or starting-point of the disease; and, if the injury were detected at the time of its infliction, *rest alone* for a sufficient length of time would probably result in a favourable termination of the difficulty in the great majority of instances. But, the injury not being detected, and in many instances not even suspected, the *rest* is not insisted upon at the proper time, and thus the disease is slowly developed, and frequently is not distinctly pronounced until so long a time after the accident that caused it, that the trifling injury which has been the origin of so much trouble has been entirely forgotten.

A pinch of the skin producing a "blood-blister," or slight extravasation in the cellular tissue, is of common occurrence, and of no great importance. If left alone it will soon be absorbed, or at most, if you let out the fluid and do not irritate the wound, it will soon get well; but, suppose even in this most trifling injury that, instead of giving it rest and time to heal, you constantly scratch it with a rusty nail, you will produce a sore, that will last as long as the irritation is continued. This is a parallel case to a joint being exercised after a concussion or wrench producing an extravasation in the tufts of blood-vessels already referred to.

The accidents to which I have referred are the three general causes of the disease which will of course be more or less modified in its symptoms according as it is developed in one or the other of the tissues referred to. If there be effusion within the joint, it is always accompanied by a peculiar distortion. That distortion necessarily arises from the fact that the capsular ligament can only hold a very small amount of fluid without being distorted. You will remember the ilio-femoral ligament that lies upon the front of the capsular ligament, running from the anterior inferior spinous process of the ilium to the trochanter minor; it is folded over the capsule, and causes it to lie close to the neck of the bone. There is a very small amount of fluid in the capsule normally, and you cannot increase that amount without increasing its capacity by *unfolding* it. As long as the limb is in the normal position, the capsule rings round the head of the bone so tightly that no additional fluid can be placed there; but if inflammation take place, and there be increased secretion, accommodation is made by the unfolding of the capsule, and the flexing of the limb when the capsule becomes loose, so as to enable it to hold this increased amount of fluid. That is the reason why the leg always becomes flexed, *abducted*, and rotated outwards. I am particular about these changes, because they materially aid you in making a diagnosis; and the thing is to be able to diagnosticate the disease in its early stages, when a great deal can be done towards its relief.

If the effusion have become very great, the limb is more flexed, more abducted, and more rotated outward, and at the same time more fixed, apparently ankylosed, as if it had been solidified by plaster of Paris; yet it is not a bony ankylosis, but simply arises from distension by effusion and from muscular rigidity.

One of the things that is sure to take place in any inflamed joint of long standing—the hip, knee, or any other joint—is atrophy of the muscles above and below it; and at the same time reflex irritation causes muscular tension or muscular contraction. The muscles that move the bone become irritated and contracted, so as to bring pressure against the diseased surfaces, which aggravates and complicates the disease from the beginning to the end. This is one of the great sources of pain and trouble which we have to overcome in these diseases. So in diseases of the hip-joint, the muscles contract and flex the limb, and would adduct it, but it cannot be adducted on account of the anatomical distension of the capsular ligament necessarily forcing the limb outward, rotating it outward and *abducting* it. Now, the adductor muscles (as all who have seen this disease must have observed) become, like catgut, intensely contracted, and feel like a strong cord. The desire to bring the limb in is on account of this reflex irritation of the adductor muscles, and the absolute impossibility of doing so is because of the capsular distension of which I have already spoken. If you take a dead body and flex the joints so as to break up the *rigor mortis*, and place it on the back so that both limbs are in their natural position; if you now bore a small hole through the ilium into the acetabulum, and forcibly inject a small amount of quicksilver, it will cause the limb to flex, *abduct*, and rotate outward at the hip-joint. By driving into the hole a small piece of wood to retain this increased fluid within the joint, you will find it impossible to extend, adduct, and rotate the foot inward, without rupturing the capsule; and the attempt to do so, if the capsule do not rupture, will force out your plug like a pellet from a pop-gun.

It is the struggle between the irritated muscles to adduct the limb,

\* Delivered at the Children's Hospital, Great Ormond Street, on July 15th, by the invitation of the medical managers of that institution.

and the impossibility of the limb yielding to their traction on account of the over-distended capsule, that cause the pain to be so great in the second stage of the disease; and it is made manifest on the inner and lower portion of the thigh near the knee, on account of a little filament of the obturator nerve which runs off there to the ligamentum teres, and a sensitive branch from it running down to the adductor muscle. This over-distension can only be relieved by puncturing the joint and letting out the superfluous fluid, or by cutting the tendon, so as to accommodate the one to the other. The treatment will of course depend upon the condition in which you find the patient; you must exercise your own judgment as to which method is to be preferred, according to the condition in each case. In this stage of the disease the pain is agonising, torturing, with loss of sleep and loss of appetite. The least attempt at movement in any way causes the most agonising shrieks; and at this period ulceration takes place in the cartilage of incrustation. The patients begin to have what are called night-spasms—the peculiarly characteristic pains that occur in the night depending, I suppose, upon the fact that the child becomes completely worn out, loses its hold on the muscles, and drops off to sleep for a second; then there is a spasmodic contraction bringing this increased pressure and movement of the diseased joint, and the child wakes up with a shrill shriek. The mother runs upstairs, and finds, perhaps, that the child has dropped off to sleep again. You hardly ever ascertain this fact unless you live in a hospital, or stay for several nights in a house where there is a child with disease of the hip-joint, when you will appreciate this thing very accurately indeed. The tension of the muscles that the child is undergoing all the time keeps the joint from movement, and makes him comparatively comfortable; but that is done at the expense of vitality. The constant effort of the child to hold the muscle still to prevent movement wears him out, and by and bye he drops off to sleep from sheer exhaustion, and then, when there is the least movement, he screams as though he were pierced with a red-hot iron; instantly the muscles are on guard again, and the child is relieved. That goes on over and over again. After awhile, ulceration takes place, and the capsule ruptures; then this imprisoned fluid escapes from the expanded capsule into the cellular tissue, and the child is comparatively easy. But the disease has still further progressed. We often think we have gained a great deal because the child is so much more comfortable, whereas the disease has only gone on to the third stage, in which effusion takes place into the cellular tissue. Almost immediately there is a marked change of attitude, or character of the deformity. The leg is immediately adducted, drawn close to the other; the toes are turned inward, and the limb is apparently shortened. If this rupture that takes place through the capsule be very slight, so that the pus oozes out by slow degrees, the change takes place very slowly; but if (as is often the case) there be a big rent in the capsule, you may find the child distorted in one way to-night and to-morrow the very reverse. The fluid has suddenly escaped; and that has always been heretofore described as the luxation which occurs in the third stage of hip-disease. I looked through your museum the other day and saw a great many specimens, but none are luxated. The theory of luxation in the third stage was proved by Dr. Alden March of Albany, New York, to be a mistake. The head of the bone is absorbed; the acetabulum is absorbed and increased in size; and the capsular ligament which surrounds the acetabulum slips up, and up, and up, and so it remains—the periosteal development, giving an additional growth of bone, makes a new attachment above, so that the capsule is still attached, and the head of the bone embraced in it only slipped up. You may call it, then, a displacement of the acetabulum, not a luxation of the head of the bone. The absorption taking place in the acetabulum and in the head of the bone, causes the limb of course to be very much shortened; and it being adducted, and the neck having been nearly destroyed (in many instances entirely), the idea of luxation has arisen; but I draw a distinction between a destroyed and changed position of the acetabulum, and a luxation of the head of the bone. I call it a luxation when the head of the bone is outside the capsular ligament; but if the ligament have been displaced or moved in its position, still embracing the head, it is a displacement, not a luxation.

So much for the pathological changes that take place; next as to the causes of this disease. My impression is, that the great error we have always committed has arisen from looking at this disease as necessarily one of constitutional dyscrasia, a blood-disease, a constitutional poison; that this is simply a local manifestation of a general disease. Believing this, we treat the system, we give internal remedies, and apply our medicines for the purpose of changing the character of the blood, instead of paying attention to the local disease which is the great source of trouble. All authors, as far as I know, particularly the older ones, have looked upon this as a scrofulous or tuberculous disease of the bone, necessarily connected with some hereditary taint or some peculiar

scrofulous condition of the system, and therefore they believed that the disease must necessarily go on to destruction, and that there was no necessity for any local treatment except counter-irritation, blisters, setons, and so forth. Internal remedies were the principal things relied upon. The result was, with all that kind of treatment with which we are familiar, always the same—viz., shortening of the leg by absorption of bone, and, finally, the consolidation of it in more or less deformed positions; and then the patient frequently came into a condition of robust health. I do not suppose there is any person in this room that cannot call to mind some old fellow with a shortened hip perfectly ankylosed, yet with a ruddy face, a good healthy complexion—a vigorous robust old man. If he had had scrofula in his blood, if he had had tuberculosis in his system anywhere, it would have remained there; and when the hip recovered, the man would have been a miserable old fellow after all. The fact of his being a vigorous robust man after going through all this trouble, proves, in my judgment, that the disease is not of constitutional origin. The fact that in so many cases the joint has been excised when the patients have been apparently at the point of death, and that they have become, when the source of trouble has been removed, vigorous, strong persons, is another evidence that the disease is not constitutional. Then there is the still stronger fact that, by making application to the local disease, and treating it irrespectively of any constitutional taint, you produce perfect results, so that the patients recover without the slightest deformity, and with perfect motion; that is the best proof in the world of the disease being local. Follow up the history of these cases, and you will find that it is a local disease. Out of several hundred cases that I have accurately observed, and taken the trouble to trace their history, the immense majority, I may say 90 per cent., occur in the most vigorous, robust, wild, harum-scarum children—boys that take their chances of danger, that run races, that climb over fences, jump out of apple-trees, kick their playmates downstairs, ride down the banisters, are reckless and careless. The sickly, poor, scrofulous child, who clings to his mother's apron, does not run the chance of getting hurt. I do not say that scrofula is a preventive against disease of the hip-joint—by no means. All things considered, a smaller amount of injury would produce the disease in one of these miserable young ones sooner than in a healthy robust child. But such children take very little chance of being hurt, and consequently the majority of cases occur in the active and robust. The injury that starts the disease is sometimes very trifling, and not observed at the time. I might illustrate this by my own experience. In getting out of one of your cabs, I have nearly torn off my tendo Achillis. You have no kerb-stone as we have, and no steps to your Hansoms; and the result was that, expecting to step down only eight or ten inches to reach the stone, I found I had to go eighteen or twenty inches, and thus I strained the tendo Achillis. If I had torn it entirely off it would have done no damage, except loss of time, because I should have been compelled to lie by; but I hurt it so little that I paid but little attention to it; and I have been walking about for a week or ten days, until I can scarcely walk any more. It is now bad enough for me to begin to take care of it. If I had hurt it a little less, it would have been more dangerous, because it would have gone on by degrees producing those conditions, that terminate in a destruction of the part.

In the first stage of the disease it is necessary to examine the child by taking off every stitch of clothes. Then, going behind, you will observe the peculiar form of the nates. The diseased side will have the gluteo-femoral fold a little dropped down; the two buttocks are not exactly alike; and you will observe, if you watch carefully, that the toe has a tendency to turn out, and the child bends his knee and hip. The sound leg is made into a solid column to receive the concussion and bear the weight of the body; the child is careful not to concussion the other at all. By careful measurement you will find that, even in the first stage, the thigh is already smaller than the other. Of course you want to examine very carefully in this stage, and it will take time to detect it; but after examining some little time you will see the gluteo-femoral fold dropped lower, the nates flattened, the line from the centre of the sacrum to the trochanter major a trifle greater than on the other side, and the leg having a tendency to be slightly abducted, and flexed at the knee. You then lay the child perfectly flat on the table. The case before us is a very illustrative case. You see the perfectly cautious manner in which the child moves; she sees everything, and keeps herself constantly on guard. There is now no movement at all at the hip; she is locked up, and she keeps herself as quiet as possible. The case is one that has gone on for some time [the mother stated that the child had been suffering for four years; that she had a slight fall at first, and did not complain of it at the time], and it is so conspicuous that anybody could find it out across the street. It is in the incipient stage, such as this child was in three years ago, that you want accuracy of diagnosis. This case has gone on to the third stage of the disease.

It is essential to a proper diagnosis of these cases to have a normal stand-point to go from, and it is this. The body of a child in a healthy state can be laid upon a flat surface, the spine lying upon the floor or table; and a line drawn from the centre of the sternum over the umbilicus to the centre of the symphysis pubis, and another drawn from the anterior superior spinous process of the ilium of one side to that of the other, cross each other at a *right angle*, when the trunk and pelvis are in a normal state. In that state, if the hip-joints be perfect, the legs can be brought so that the popliteal spaces can be made to touch the floor or table. Now, whatever position the other leg has to be kept in, in order to get these two lines at a right angle with each other that is the characteristic deformity of the leg. A sofa, bed, or lounge, will not do for this examination—it must be done on a *solid foundation*. In this case, you see, in order to get these lines right, I am compelled to hold the leg flexed, but it is simply adducted. That is a very important point. It is an evidence that the capsule has become ruptured. If there were effusion in the capsule, the leg would be adducted and rotated outward. The fact that it is adducted, and inside the central line, as you see, is evidence that the disease has gone to the third stage, and that the capsule has become ruptured.

You see that the child, when held in the manner in which I am now holding her, has no pain. Putting my hand upon the pelvis, I make movements, and you see that the joint is not ankylosed. Seizing the pelvis with one hand, and passing the other under the knee, and making moderate extension in the direction at which the deformity has arrived, I make movements, and the child has no pain whatever. I let her go for a second, and then, on making the slightest movement, you see what pain she suffers. Now, I have ankylosed that joint; there is ankylosis perfect and complete to all appearance; it is muscular rigidity that has produced it. You see here the disease aggravated and continued by pressure. You could not have a better illustration of the practical working of the principle of extension.

You perceive that the child can be moved about without any difficulty if she be handled properly, and the limb slightly extended. A person accustomed to it can take up a child with apparently the greatest carelessness, and will *seem* to be acting with perfect brutality, without giving any pain whatever. He knows how to apply his force; and yet in a single instant he can produce the most agonising torture. See the way in which the child locks herself up, and makes herself perfectly rigid the instant I omit my extension.

Pressure causes absorption. By constant pressure of the head of the bone against the acetabulum, there is absorption of the head and absorption of the acetabulum; destruction takes place, and terminates in an abscess which finds an outlet somewhere; or else it goes on to ankylosis.

Many persons apply a plaster of Paris splint in these cases. This is good, so far as it keeps the part still; but, as it lacks the power of extension, it does not accomplish all that is desired. It is better to have the limb recover with motion than ankylosed.

If I take hold of the pelvis, and make moderate extension, the child is free from pain; if I put it down straight I hurt her, for I put the psoas magnus and the iliacus internus on the stretch. The straightening is to be done by slow degrees. You see the result in the case of the other child, whose leg was like this, but is now much better, from the fact that extension has been applied for some days. It is best to put these patients to bed and apply the night extension. You put the extending force on the diseased limb very nearly in the angle of deformity as you find it; lowering your extension by slow degrees, until, in the course of a week or ten days, or two or three weeks, you get the limb as straight as in the case of this other child.

This is really the proper time to apply the instrument which I propose to put on this child in order to enable it to take out-of-door exercise. If you take it in the early stage of the disease you do not want to do that; but, this child having undergone this deformity, we must take her as we find her.

*Mode of applying Extension.*—We take two strips of adhesive plaster two or three inches wide (according to the age of the child), and extend them from just above the ankle on each side, and long enough to reach two or three inches above the knee, first having had a web sewed fast to the lower extremity of the plaster for the purpose of putting on a buckle for night extension. These straps are secured by a roller, as you see. I always put on the plaster without heating it. When heated, plaster is very apt to slide from itself; it moves off from the web or cloth on which it is spread. If you heat it, it burns the skin, or glides away from itself; but if it be put on with gentle pressure, this does not occur. I am careful not to make the upper end of the plaster stick before reaching it. If you put on the plaster with a fold and get a pucker in it, the effect is the same as pulling your boot on with a pucker in your stocking: it does not hurt you much till after dinner;

before bed-time it is unbearable. The plaster has to be worn many months, and it should be applied carefully. I mention these little matters as the result of my own experience and observation. You will only learn by making blunders; and having made many myself, I try to teach others to avoid them. It is remarkable how easily the plaster may be worn for months if it is smoothly and comfortably adjusted. The skin should always be thoroughly washed, and carefully *wiped* before applying the plaster. Having gone above the knee for an inch and a half or so, I reverse the plaster over the roller. At first I make the roller hold the plaster until I get above the knee; that is, simply to catch a bite, as it were, on the condyles, so that extension shall be made upon the hip, and not upon the lateral ligaments of the knee-joint. I then reverse the plaster and bring the roller back over it; and now the plaster is made to hold the roller in place so that it will not slide. This can now be worn for three or four months. If the bandage become dirty you can take it off without removing the plasters; or you can put a long stocking over it.

This is now ready for night extension. We next put on the plaster to apply an instrument for day extension, so that the child can run out of doors. This is done by taking two fan-shaped pieces of plaster, and sewing on to the pointed end a piece of webbing just wide enough to fit the jaws of the instrument. The instrument (Fig. 1) is made of two

Fig. 1.—Instrument for extension.

pieces of steel, one sliding into the other, as you see, and made to lock by a key. This rod terminates in two branches that go over the thigh, and come on to the inner portion of it. I formerly made the instrument to go down the whole length of the leg; but finding that it only stiffened the knee-joint, I prefer now to make it go over only the thigh. By means of a cross branch, you take the extension from the inside of the thigh. The rod should be made to extend from an inch and a half to two inches above the condyles of the femur up to the crest of the ilium. It ends in a little roller, over which the webbing is to play, and it is capable of being elongated and shortened at will by the key. The

upper portion terminates in a ball-and-socket joint in a little steel band which runs round just under the crest of the ilium. At each end of this band is attached a perineal pad, which runs under the perineum, and is buckled; and counter-extension is made on the perineum, so that the child walks on the perineal pad instead of on the hip-joint. This was a desideratum which I was always trying, for a great many years, to obtain, but did not succeed. A man named Davis was the first to make an instrument accomplishing this object. It was a piece of steel running down the whole length of the leg to the ankle. Extension was made by a joint and a buckle, but it could not be gauged, regulated, or controlled with ease or accuracy; still the principle of keeping up extension, and at the same time permitting motion, was made first by this man Davis. Had he remained an honourable man, true to his profession, he would have deserved to have his name passed down to posterity with respect; but having taken out a patent for his instrument, he has incurred the reprobation of every honest and honourable man. We will, however, give the devil his due, and admit that this man was the first who made an instrument accomplishing this object. But his instrument has been so modified and so immensely improved, that his patent is of no avail.

You lay the instrument over the thigh. If it do not fit exactly, you can bend it with the fingers; if it be a little too tight, you can spring it apart. You put your thumb and finger opposite where the two lower jaws come, and you will know the place to commence the application of your plaster for the extension of the thigh. Sometimes the pain is so intense that it is necessary to give chloroform. The plaster is put on and bandaged round, as you see, working in and out basket fashion, so as to cover any inequalities of the skin. After a few applications, you learn how to do it snugly and smoothly. By having the plaster cut in slits at the upper ends, it can fall in pieces or fall together more readily, and thus be applied more smoothly.

I used to put the bandage over the pelvis, in the form of the figure 8, but I prefer the plan of splitting it in strips and reversing it over the roller, as you now see. Remember that it is not requisite to pass above the trochanter major. It is hardly worth while to draw the anatomist's attention to that; but I have seen the best surgeons thoughtlessly apply the plaster clear above the joint, and of course it only pulled the pelvis instead of opening the joint.

Fig. 2.—Child before the application of the instrument.

If this instrument had been put on the child before she became so much distorted, you can well understand how much greater the advantage would have been; or had she been kept in bed two or three weeks, and the limb pulled down straight; but we will take the worst kind of case, and see whether it will do any good or not. As I am compelled to put on the instrument immediately, I press the plaster on, rather than apply it by heat; and by keeping the limb extended, I can press the plaster home without hurting the child. But it is better to

leave it for a few hours to get an attachment. [The accompanying sketches (Figs. 2 and 3) show the child before and after the instrument was applied. In a few minutes after its application, the child walked around the room in perfect comfort, sat down on a chair, and got up several times to show the perfect freedom of motion in the joint.]

Fig. 3.—Child after the application of the instrument.

This treatment may be required for months and months; and when the patient is well, I make him wear the instrument for weeks or even months afterwards, as a means of protection or guard. If the child be small, no crutches are required; but, of course, if the weight of the body be too great to be sustained by the plaster, crutches must be added. The advantage is, that the ligaments are kept in movement. The objection to the *fixed* treatment is, that the ligaments which are not involved in the disease become diseased by rest. By giving them motion, they are kept in a normal state. A piece of old leather, if you do not handle it and keep it supple, is good for nothing.

When the disease has gone on to another stage where sinuses have occurred, and discharge pus, when a probe leads down to dead bone, there is nothing to be done but to excise it by making a small incision above the trochanter major, midway between it and the crest of the ilium, over the top of the acetabulum—a semilunar incision, the belly of the D covering the posterior part of the trochanter major, going straight down to the bone, *through* the periosteum. You then pull the soft tissues on one side, and, taking a small but strong curved bistoury, go as far around the bone on each side as you can reach, at right angles to your first incision, so as to divide the periosteum completely; you then take a strong firm periosteal elevator, with a large handle, and the end slightly curved, and go into this little triangle; you *peel* off the periosteum, and, as a matter of course, all the muscles with it; by opening the joint thoroughly, and turning the head of the bone out, the periosteum is peeled off from the inner portion; you then saw off the bone above the trochanter minor. I believe that this is better than cutting through the neck. If you go through the neck, the trochanter major comes over the hole and prevents discharges; whereas, by cutting off the trochanter major along with the neck of the bone, you leave a perfectly free opening for the discharges from the diseased joint; and by peeling off the periosteum in the way which I have described, you carry with it all the muscles that move the joint; and if you then keep the leg pulled out to its proper length, by putting on a pair of wire breeches, you can send the patient out into the air the very next day (Fig. 4).

Here is a photograph showing the result of a case that has been excised. Three inches and a half of bone have been taken away, and the head of the bone united. Here is another, in which four inches and a half were removed, and the man recovered with a movable joint. This which I now show you was the first case performed in America. I operated on the patient in 1852. I invited many surgeons of New York to come and see the operation; but no one attended, as at that time it was thought to be unjustifiable. The patient is, as you see, a handsome

woman, and no one would observe any defect in her. Here, however, is the most successful case, in which four inches of bone were removed. The whole acetabulum was destroyed; the head and neck nearly

Fig. 4.—Wire-breeches.

absorbed. There were several sinuses leading down to dead bone. I removed the head and neck, cutting it off just above the trochanter minor; but, finding the disease extending further down, I pushed the femur up, and sawed it off again. By keeping the limb extended, if you will peel off the periosteum in the manner which I have described, the bone will be regenerated, and be as good as ever. By extending it sufficiently, you make the limb as long as before. When you have got the bone regenerated, and before consolidation takes place, you commence passive movements, and in that way obtain an artificial joint, as in the case of an ununited fracture. By constant movements you prevent ankylosis; and, as the muscles have all been carried off with their insertion at the periosteum, you have certainly got the normal position from them to be moved again. The proof of it is in this boy. He bends his leg at right angles; he can kick higher than his forehead; and he won a pair of silver skates two years ago in a contest with some very good skaters on the Central Park pond in New York. The leg is almost exactly of the same length as the other, and the motions are perfect; and yet here you see four and a half inches of his femur, and the acetabulum was perforated.

I have been rather surprised to receive a letter from Mr. Barwell, who said he was going to publish it in the *Lancet*. I hope, for his own sake, that he will not. He dislikes my plan of removing the periosteum. Of course every one has the right to select any plan that suits him best. I am extremely reluctant to be dragged into controversy; and, without answering anything of the kind, I will draw your attention to the answer which you can make yourself. If you take an orange and cut a slit down through the skin, I should like to see any of you with a sharp penknife peel the orange out of the skin without splitting the skin or sticking the knife into the orange; or if you take a straight broad knife like a scalpel, and take the orange out without damaging the skin or making an occasional hole in the orange, you are more dextrous than I am. But if you will take a knife and cut across the skin, you can take the handle of a silver spoon, slip it in, and peel round under

the skin, and separate the orange from its covering without tearing it. So it is in regard to the femur. In *dissecting* off, you tear the periosteum into shreds, destroy its vitality, and prevent its doing the good which you want it to do. By commencing *above* and "prying" it off, without first limiting its extent by the circular incision above referred to around the femur, you are in great danger of loosening its attachment to the bone below the point where it is to be sawed off—where you do not want to loosen it. You want the periosteum left attached to the femur. Therefore I prefer cutting down over the trochanter major, through the periosteum, down to the bone, as far as opposite a line a little above the trochanter minor. Taking a small bistoury, and going at right angles to this first incision, half-way round on each side, I thus limit the line of removal of the periosteum to the place where section of the bone is to be made; and below that point the periosteum remains attached to the bone. Since adopting this plan of operating, and always using the saw to divide the bone, instead of the pliers or bone-forceps, I have not had exfoliation follow my operations as in former instances. To prove that this is the better way, I may mention that I have operated forty times, and thirty of my patients are walking about with excellent movement of the joint; and you here see daguerreotypes of them. Eight or ten of them, I am confident, might be walked into this room, and not one gentleman here would be able to say which leg was operated on. These are cases in which I operated in the way I have described. I did not learn to do this the first time I tried; and some of the cases, therefore, did not go on so well. I have had some short legs; and I have had cases where there was a good deal of exfoliation because I did not peel the periosteum properly; and I have had exfoliations because I cut off the femur with a forceps, which in my judgment ought not to be done.

Let me, before I conclude, say a word on operative surgery and anatomical surgery. You sometimes see beautiful dissections. Men will hold the knife like a pen, lay out the various tissues, and give a very pretty dissecting-room demonstration. Every surgeon should go through this anatomical surgery in the dissecting-room, and do it thoroughly and frequently; but, when he comes to apply his knowledge to the living human being, let him be an *operating* surgeon, and go straight to the place which he wants to reach, without splitting hairs and dividing endless series of fasciae.

**CONTAGIOUS DISEASES ACT.**—In reply to Mr. Baines on Monday last, Mr. Bruce said that the report of the Commission on the Contagious Diseases Act would be presented to the House at the very earliest possible moment. Although the report was unanimously signed by twenty-three out of the twenty-five members of the Commission, one of the two being absent from ill health and the other being on duty in India, yet as a matter of fact two-thirds of the members might be said to be in favour of a qualified compulsory application of the Act, and one-third—seven at least—of them were in favour rather of strengthening than of weakening the Act, and six of the number were practically in favour of repealing all compulsory legislation, but all were in favour of introducing some further legislation for the purpose of adapting the modified legislation to the acceptance of the whole country. No doubt the report of the Royal Commission on these acts was intended, not merely for the information of the Government, but of Parliament and the whole country, and it appeared to the Government that at this period of the session it would be impossible to give due time for the consideration of the report by the Government or the country, so as to introduce lasting legislation on the subject, and it was, therefore, not the intention of Government to bring forward a bill during the present session. Under one set of circumstances it would have been their duty to do so. Had the statements which had been so frequently made, and to which much of the deep and strong feeling which undoubtedly existed in the country was owing, been confirmed by the report of the Commission—had it been shown that those outrages which had been complained of had been committed, it would have been the duty of Government under almost any circumstances to have introduced a measure to repeal an act capable of such abuse. But he might be permitted to read the words of the report:—"We generally find that the result of our inquiries has been to satisfy us that the police are not chargeable with any abuse of their power, and that they have hitherto discharged their difficult duty with moderation and caution." Now that feeling was unanimous, and examination of the evidence showed, as he was happy to state, that not only had the statements been grossly exaggerated, but that a great many of them were sheer inventions. The House would see that the substitution of any legislation which would require, both from Government and the House, deep and anxious consideration, was a subject which could not be undertaken at present.

# THE HASTINGS PRIZE ESSAY,

1870.

## ON DIGITALIS: ITS MODE OF ACTION AND ITS USE.\*

By J. MILNER FOTHERGILL, M.D.,

Late Senior Resident Medical Officer to the Public Dispensary, Leeds.

**Mitral Obstruction.**—In mitral obstruction the same series of symptoms present themselves as in mitral regurgitation. The obstacle here is in the entry of the blood into the ventricle; the orifice being narrowed, it is necessary that the blood be poured in under greater pressure. The feeble but regular pulse tells how imperfectly the ventricle is distended in each diastole. There are the necessary changes in the right ventricle and pulmonic circulation, and a general thickening from the ventricular wall to the smallest vessels, which ensue from the natural conservation of the system; and as long as these compensatory changes are kept up fairly, the sufferer is scarcely conscious of his injury. But, sooner or later, the compensation either fails, or secondary diseases follow the lesion and its sequelæ. We can only take the natural indication of compensatory hypertrophy, and aid it, so far as in our power lies, by administering agents which assist the natural attempts made in the manner explained in a previous section. We must keep up the powers which are to drive the blood through the narrowed orifice, and that can only be attained through increasing the pressure by an increased *vis a tergo*. The changes in the lung when the pulmonic congestion has led to disease further obstruct the flow, and impede the action of the right ventricle. Death is approaching from failure of the right ventricle, and its action must be kept up at all hazards. Increased action in it leads to a freer circulation through the lungs, the asthenic congestion being the cause of the dyspnoea. We must obviate the tendency to death, and meet its approach by appropriate means; and in this valvular lesion it is failure of the right ventricle against which we have to guard.

**Mitral Regurgitation.**—In this valvular lesion, even more remarkably than in mitral constriction, we find changes due to overcharge of the pulmonic circulation. The blood is driven into the ventricle without obstruction, but part is forced back at each ventricular systole. This regurgitation overloads the blood-vessels behind, and the blood is forced into the ventricle on diastole under increased pressure; the consequence is, that the left ventricle is over-distended, and a certain enlargement of the ventricular cavity follows, usually accompanied by hypertrophy. This change in the left ventricle is always to be borne in mind, and not to be overlooked in the question of administering a drug which produces increased ventricular contraction. For it is obvious that, while we might increase the power of the right ventricle, if the left remained unaltered and the agent acted equally on it, as it does, all our increased power might be met by an unnatural contraction of the left, more than negating the good to be got from the increased activity of the right ventricle. If the left ventricle remained without change, the administration of the drug would certainly be decidedly contraindicated; the danger of over-contraction of the left ventricle would constitute a more serious danger than the one we wished, as in mitral obstruction, to relieve. But the increased pressure under which the blood is poured into the left ventricle from the distended auricle and veins behind it, more than counterbalances that risk. In fact, the action of the agent on the left ventricle, is equally beneficial to prevent its becoming over-distended and yielding before the increased centrifugal pressure of the blood driven into it under greater pressure from behind. In mitral regurgitation, the benefit to be derived from the administration of digitalis is as manifest as in any condition of cardiac disease. The mode of repair which we find to have been set up by the natural efforts of the system in persons in whom valvular lesion has been discovered by some chance, is a compensatory thickening of the muscular fibre of the right ventricle and the pulmonic vessels, and an increase of the capacity of the latter to withstand the stress upon them from the addition of the blood which regurgitates to that which is sent in from an enlarged and more powerful ventricle. The vessels, though consisting of tissue not readily taking on increased growth, change gradually to keep pace with the increase in the power of the right ventricle, and retain this hypertrophy even when the efforts of the right ventricle are waning. The failure of the right ventricle is again the avenue by which death is advancing; and

by increasing its efforts we increase the blood-pressure, and increase its opposition to the regurgitation, and thus more blood is thrown into the aorta at each ventricular systole, while increased arterial tension leads to better tissue-nutrition. Of course the condition of the vessels must be taken into consideration, as will be considered more at length under the head of contraindication. Even pulmonary congestion does not militate against the exhibition of digitalis in mitral insufficiency; in fact, usually it is much relieved by the increased action of the right ventricle. The effect of compensatory change, and, of course, of artificial aids to it, is much more obvious in mitral than in tricuspid insufficiency. The increased action of the right ventricle is not lost over the length of the pulmonic circulation, as in the increased action of the left ventricle in tricuspid regurgitation. In fact, in mitral regurgitation, we see most constantly the effect of conservative compensatory changes behind the lesion; and thus, of course, agents aiding in effecting that compensatory change are of the greatest value. It is clear, too, from the tendency of the left ventricle to yield to the increased centrifugal pressure of the blood driven in by the distended auricle and veins behind, that the stimulated contraction in it from the action of the drug does not constitute an objection to its use. It is only by observing what changes have gone on spontaneously in individuals suffering from mitral insufficiency, and yet capable of sustained exertions, and further observing how that compensation commences, that we can get a clear idea of what to attempt to achieve, and of the mode by which relief can be afforded. These indications we must carefully follow if we expect to give any therapeutic aid to the sufferer, either during the disturbance which follows the first appearance of the lesion, or when the compensatory change is failing.

**Aortic Obstruction.**—In aortic obstruction, a totally different change takes place from what goes on in mitral disease; and as long as the mitral valve remains perfect, the change is confined to the muscular walls of the left ventricle. It is a simple question of increased power; and as the contracting action of interstitial inflammation of the valves and orifice is very gradual, the muscular change can keep pace with the changes. Thus we see in aortic obstruction usually a simply hypertrophied left ventricle. There is not dilatation, because there is no increase in the centrifugal pressure of the blood poured into the ventricular chamber. A natural increase in the muscular power allows an equal quantity of blood to be driven through the orifice, now narrowed, in an equal time; there is no disturbance of balance; the hypertrophy here is most commonly perfectly compensatory, and the compensation lasts longest. The existence of aortic obstruction is most frequently discovered casually, and not by any heart-symptoms on the part of the patient. In conditions of failure of the ventricle, from general debility or atheroma of the aorta interfering with the propulsion of the blood into the coronary vessels, and consequent imperfect nutrition, increased ventricular contraction at once relieves the patient, and tends to produce a comparatively permanent improvement. My reasons for regarding the improvement following the use of digitalis in this affection to consist in increase in the driving power, rather than in slowness of the ventricular contraction, as stated by Sir Dominic Corrigan, have been given above, and need not be repeated. It may not be out of place to add here that hypertrophy is the mode of repair adopted by the efforts of nature, and not any reduction of the number or the rapidity of the contractions. Relief, too, follows the use of digitalis when there is no appreciable retardation of the pulse. As to the question, it is merely one of time or power, and the latter is evidently the correct explanation. The effect of digitalis would depend largely on the condition of the muscular fibre. If there were only a passing disturbance, and the muscular fibre were fairly structurally sound, small doses alone would be required; if the hypertrophy were passing into degeneration, much larger doses would be called for. In aortic obstruction, the therapeutic aid to be given is a very simple question; and increased ventricular contraction, however produced or attained, at once restores the disturbed equilibrium and gives relief.

**Aortic Regurgitation.**—In aortic regurgitation, however, it may be made a matter of great question how far any interference can be beneficially available. In this affection, we meet with the true *cor bovinum*, an excessive enlargement of the left ventricle, both in thickness and cubic space and cavity. The regurgitation through the aortic valves produces increased and sustained contraction of the ventricle. The backward flow on the arterial recoil is no longer caught and arrested by the semilunar valves, but falls on the fundus of the ventricle, and thus normal contraction is prolonged into sustained contraction. On the diastole, however, the blood flows through the insufficient semilunar valves, as well as through the mitral valve; the quantity regurgitating being added to the normal amount from the auricle, and then the centrifugal pressure is increased and dilatation follows. At the same time, a great increase of the muscular walls follows the increased necessity

\* Continued from page 89 of last number.

for contraction. There is not here simple dilatation, for the ventricle can empty itself without impediment, and the sustained contraction calls out more muscular effort. Between the two forces of increased distension and increased and sustained contraction, the ventricle becomes both enlarged and thickened. But the increased volume of blood thrown at each ventricular systole into the aorta, and over-distending it, leads sooner or later to endo-arteritis; the aorta is not only enlarged, but its walls become diseased and lose their elasticity; thus goes one element in the propulsion of blood in the coronary arteries. At the same time, the regurgitation takes off from the arterial recoil, as is well seen in a sphygmograph tracing, and the recoil no longer fills the coronary arteries, but is lost in the regurgitation; this adds further to the diminished flow through the coronary arteries. Sooner or later, the hypertrophy passes into degeneration, and the muscular walls lose their structural integrity, and with it their compensatory usefulness. The more diseased and less elastic the aorta, the more defective becomes the coronary circulation, and the tissue-nutrition connected with it. It would be difficult, then, to move in this complicated condition without finding the risks increased in strict proportion to any benefit that might accrue. Increased ventricular action might produce increased tension, and consequent better heart-nutrition; but then there is the increased danger of rupturing the diseased arterial coats. The benefit is not without alloy; and it may be made a matter of question how far we can safely interfere at all. Each case must stand on its own peculiarities, and the treatment be adapted to the patient's special requirements; but digitalis can rarely be indicated. In the earlier stages it is contra-indicated by the hypertrophy and sustained contraction. Its administration is hazardous; and the risk of driving the ventricle into a contraction which may never be relaxed, and of bringing the heart to a stand-still in systole, is greater than any risk accruing from inefficient contraction; in fact, in this lesion the hypertrophy is usually so extreme as to need no abetting.

*Disease of the Right Side.*—The effect of disease of the right side, as regards the muscular walls, has been considered above. In valvular disease of the right side, we do not know any peculiarities connected with the pulmonary orifice: disease here is rare, and the same indications and contra-indications would not exist as in aortic disease. It is widely different in the affections of the right auriculo-ventricular valves.

*Tricuspid Regurgitation.*—In tricuspid regurgitation, repair is almost forbidden by the anatomical arrangement of the parts. There is no possibility of compensatory change, at a little distance behind, coming to the rescue and backing up the insufficiency, as in mitral disease. The tricuspid is far removed from any force which could in any way make up for its deficiencies. As to the theory of the tricuspid being naturally and normally imperfect, and admitting regurgitation on any distension of the right ventricle or obstruction before it, or what was called "safety valve" action, it is now generally abandoned. It would, if it existed, militate strongly against any compensatory change in the right ventricle, which never takes place without some enlargement of the cavity of the ventricle. It would be a most common thing to find jugular pulsation, cyanosis, dropsy, etc., on any stress falling on the right ventricle, which we know only to occur when the tricuspid has become incompetent. These evidences of tricuspid incompetence are of portentous moment, and are the ordinary harbingers of serious danger to the organism, and only too commonly of approaching dissolution. If the "safety valve" theory were a correct one, they should follow inevitably in any pulmonary affection which might try the right ventricle. Instead of that, their appearance during a chronic cardiac affection is usually the precursor of death: showing that the last anchor, the tricuspid valve, has given way. It occasionally happens that a lesion in the tricuspid occurs as a primary affection. The progress of the case is rapid and downward; the venous engorgement and its concomitants are present at the first, and not at the last of the case. Dropsy sets in while there may be a fair amount of vigour, and the patient going about. There is a rapidly accumulating coma from the venous congestion of the encephalon; there is asthenic congestion of the lung; there is engorgement of the liver and kidney, and from it, again, uræmia. The patient's troubles come upon him in quick succession, and the last change is not long delayed. All art seems useless; there is no ventricle at a little distance behind, to back up the lesion, and no compensatory change can be organised. The administration of digitalis is apparently of no benefit whatever; the increased action of the left ventricle is too far distant to be of any avail. The action seems lost over the length of the systemic circulation, and in the dilatability of the veins. This is the only action available. Purgation may relieve the venous engorgement; but

nothing can compensate the lesion. The prospect is hopeless; and though we may try to be of service to the patient, it is with a painful consciousness of the futility of our efforts. The free use of digitalis was of no apparent use in a case where it was given unsparingly enough, in order to ascertain if any good could accrue from its empirical use; though reason could advance nothing in its favour. When the tricuspid fails in chronic cardiac disease, the patient's prognosis is hopeless, and relief of some of the most urgent symptoms is all that we can hope for.

*Tricuspid Obstruction.*—The existence of this affection is questioned, so rare is it; but that is no proof of the impossibility of its occurrence. When it does occur, digitalis and all other cardiac neurotics would be useless, for the same reasons as in tricuspid insufficiency.

In all valvular affections, digitalis is useful or useless entirely as it is possible to produce conservative compensatory changes in the muscular walls. In disease of the left side, by following the indications thrown out by spontaneous accessory growth, we may be of the greatest service in either aiding the production of the compensatory change, or assisting in its continuation when beginning to fail.

*Degeneration of the Walls.*—This was once considered to negative any recourse to digitalis, when it was regarded as a cardiac sedative; and this was quite consistent. Our modern acquaintance with its action tells us, that in degeneration we may resort to it without alarm, and not only that, but with confidence. In degeneration of muscular fibre, no action can affect those fibrillæ which are converted into fat-globules; any action must affect the sound fibrillæ only. It is obvious, then, that digitalis may, by stimulating the sound fibres, produce not only relief to the general symptoms, but may even aid in somewhat improving the structural condition. Of course this will depend to a great extent on the causation of the degeneration. If it be connected with atheroma of the aorta, and thus a preservative lesion consequent on that atheroma—if the degeneration arise from impeded circulation through the coronary arteries from loss of arterial recoil, due to the loss of arterial elasticity, then the administration of digitalis will, while obviating one risk, increase another. But, if it be due to other causes, as pericardial adhesion along the track of the coronaries, then digitalis will assist us in our efforts to bring about improved tissue-nutrition, by improved ventricular action. The degenerate walls yield to centrifugal pressure, and do not contract completely, and dilatation follows. Then digitalis will be useful, as described in an early section; and the condition of the muscular fibres will not affect the treatment, except in so far as it diminishes the prospect of success. The possibility of effect on the capillaries, and of their contraction offering an opposition to the flow of blood, is put forth by Brunton as an objection to its use. But this is practically no objection to the use of digitalis, as clinical observation has convinced me. The increased action of the heart more than counterbalances the capillary contraction. Thus in a frog, when a watery infusion of digitalis was applied to the web of the foot, the contraction following almost completely arrested the circulation through the part. The administration of digitalis by the mouth restored the circulation. If, then, the increased action of the heart was visibly efficacious where the infusion, applied locally, produced contraction of the vessels, and the increased ventricular action was apparent in so small a section of the circulation, the fear of any stress thrown on the heart by capillary contraction, affecting its power to contract, must be a hypothetical one only. The frequent administration of the drug in liberal quantities has never yet in my experience been followed by any untoward result.

*Angina Pectoris.*—In angina pectoris, the use of digitalis is novel. Fuller, from his conviction of the tonic action of digitalis, proposes its employment in angina, but gives no experience of his own, merely suggesting its use. Many views exist as to the nature of angina pectoris, as to whether it occurs in healthy hearts and is merely neural, a hyperæsthesia of the cardiac plexus (according to Romberg), or one of the most important symptoms of muscular degeneration, being in fact pathognomonic of it; hence this is a very difficult subject to approach in the direction of therapeutics. In true angina pectoris, certainly not mere cardiac asthma, occurring in a patient where there was strong reason to regard it as in its nature neural, and where the attack was usually produced by passion, lasting two or three hours, and little if anything relieved by diffusible stimulants, as ammonia, chloric ether, etc., the addition of thirty minims of tincture of digitalis, repeated at the end of half an hour, gave great relief; and so different was the result of the treatment when the digitalis was added, that there could be little or no doubt of the connexion being consequential. Further use of it in these attacks in the same person corroborated that belief. The next case which occurred was in a patient where there was strong reason to suspect the existence of fatty degeneration. In a paroxysm of angina, encouraged by the success in the other case, I gave

\* For an able investigation of this subject, see T. W. King's article in *Guy's Hospital Reports* for 1839.

digitalis with very satisfactory results. Of course, the question of a rational conception of its action is difficult in the presence of so many various views as to its pathology; the old idea of spasm is now giving way to an idea that it is arrested, or nearly arrested, ventricular contraction, which is the real state of the matter. There are those who believe that angina pectoris is connected with spasm of the coronary vessels, or with bony plates in the sinuses of Valsalva getting across the mouths of the coronary arteries and obstructing them, or, rather, the circulation through them. Certain, however, it is, that whatever the exact neural condition may be found to be, or even if angina may arise from temporary action not neural, it is commonly associated with hearts that give at other times evidences of impaired tissue-integrity. Whatever it may consist in, my experience in these two cases shows, firstly, that the administration of digitalis is not harmful, and, secondly, that there appears to be such benefit following its administration as to lead me to the conclusion that it exercises a remedial action over this condition.

**Cardiac Asthma.**—In cardiac asthma or false angina pectoris, where there is evident distension of the right ventricle accompanied by palpitation, dyspnoea, and lividity of the face, frequent use of digitalis has led me to a conviction that it is certainly our mainstay. I have learned in this condition to give it freely and fearlessly, with confidence, the result of experience; and I have not yet been disappointed. The stimulating action on the sympathetic cardiac ganglia, and the effect on the muscular fibres under their control, is just the exact action which it is imperatively necessary to rouse in order to overcome the train of accumulating evils, as pulmonary congestion, cyanosis, and carbonic acid poisoning, which wear out the patient's existence, if he do not die of the more rapidly acting blood-stasis. Theoretically, this is the action of digitalis as learnt from physiological experiment; clinical observation demonstrates the soundness of the view, and further indicates it as a valuable addition to our means of controlling a condition which always is one of imminent danger in itself, tending to cut off the organism suddenly, and which, when repeated or long continued, certainly produces secondary derangements and complications, as emphysema, dilatation of the right side of the heart, with further pulmonary congestion, more frequent and prolonged dyspnoea, oedema of the lung, and, in fact, a constantly widening vicious circle of troubles, which render the patient's last days an intolerable misery to him. The relief of this terrible, and by no means uncommon condition, lies in rousing the action of the distended right ventricle; and that this may be done without bringing the left ventricle to a standstill in systole, is certain. For an explanation of this apparent anomaly, see the section on mitral regurgitation.

**Temporary Cardiac Conditions.**—From cardiac asthma we may pass on to the consideration of passing or temporary cardiac conditions, and to the means of treating them. For instance, in failure of the right ventricle in fevers, and in pulmonary affections, in shock, in palpitation, we must first satisfy ourselves as to the condition before proceeding to treat it; it is on our knowledge of the exact pathological condition that the efficiency of our remedies must depend. The whole question is a comparatively new one, and is most important; no more important addition could be made to our stock of therapeutic knowledge than a proper insight into these conditions, and the means of acting on them. We will first take failure of the right ventricle in acute asthenic conditions, commonly called cardiac asthenia.

**Cardiac Asthenia.**—In this condition we find the pulse furnishing us with the precursory evidences of approaching death. We find the pulse mounting in number, and its strength in inverse proportion; after a while there is an occasional intermission or irregular beat; then the intermissions come more frequently, and in time in clusters; the breathing is hastened and rapid, even out of proportion to the pulse; and we all know that the patient is in imminent danger, and usually dying. Now, of what are these symptoms indications? For, on the diagnosis must rest our only rational expectation of being of real service to the patient. Well! what does the *fast moriens* table say? Usually in these conditions the left ventricle and the arterial system are empty and contracted, the right ventricle and venous system turgid and distended with blood. This throws some light on the symptoms. The right ventricle has become distended and contracts inefficiently; the blood is not circulating freely through the lungs, they are asthenically congested, partly from vaso-motor paralysis, partly from an altered condition of the blood itself. The quantity of blood pouring into the left ventricle is only equal to imperfect distension. The ventricles ordinarily act synchronously, in consequence of a large number of fibres being common to both ventricles, describing a figure of 8; and the left must keep time with the right ventricle. Thus, as the distended right ventricle always full is acting inordinately fast, expelling a small quantity of the top of the ventricular contents, the left is contracting on its diminished contents; consequently, we have a small

arterial distension as felt at the radial pulse. It is clear that the more distended the right ventricle, and the more imperfect its contractions, the less blood flows into the left ventricle, and thus the rapidity and feebleness increase hand in hand. The symptoms are plain enough, and the fuller the venous system the emptier the arterial; the more distended the right ventricle, the more imperfectly filled is the left. The intermission is connected with the state of the right ventricle, not so much with any difficulty in the left. And long before the intermission in the radial pulse is apparent, an intermission can be felt on applying the ear over the heart; the intermission can be heard before the condition of the right ventricle so affects the left as to be felt in the radial pulse. This condition is common in acute asthenic disease as well as in diseases of the respiratory organs. In disease of the respiratory organs the engorgement on the right side is most readily apparent, but not so in acute asthenic disease. In bronchitis, for instance, the original obstruction is almost mechanical in its operation, but it soon leads to chemical alterations. These chemical alterations and their consequences are of the highest importance; and more especially in their bearing on the right ventricle. Both in disease of the respiratory organs and in acute asthenic conditions, we have an accumulation of carbonic acid in the blood. In respiratory affections the injured organs do not admit perfect oxygenation; in acute asthenic disease we have not only a well known tendency to acute asthenic congestion, hypostatic or other, but also an increase in the products of waste. We have thus the venous blood more than ordinarily laden with carbonic acid, an agent which has a direct effect in paralysing the heart when brought into contact with the endocardium. Thus Cyon so arranged a stream of serum made to flow through a heart, as to be able to add a quantity of carbonic acid or to withdraw it from the serum. When the carbonic acid was added, cardiac paralysis came on; when withdrawn, the cardiac contractions were resumed. For a short account of this most interesting and instructive experiment, the reader can consult the Sydenham Society's *Year-Book*, 1867-1868.

Here we see experiment corroborating what clinical experience had taught. The right ventricle, as being connected with the venous system, is also more distensible, and is commonly distended, as a matter of habit; every severe exertion or shortness of wind congests or distends the right ventricle. There is thus a readiness of distension about the right ventricle which allows the chemical agent to act effectively. Thus the blood, more and more laden with carbonic acid, acts on a ventricle becoming more and more distended, and tends still further to paralyse any power of contraction remaining; while increasing inability to contract leads to further and more imperfect oxygenation. Under this action and reaction, the condition is commonly followed by cessation of the ventricle and death. The frequency of this condition is such as to prompt our most active interest in it, and to strive earnestly after some means of acting upon it. The failure of the right ventricle is the door by which death enters; and it is our duty to obviate the tendency to death, by all means in our power. Even bleeding, on account of its temporary agency in relieving the distended ventricle has been advocated by no less an authority than Dr. B. W. Richardson. Stimulants have been largely resorted to; and in the treatment of typhoid pneumonia, where the condition is well-marked, Dr. Hughes Bennett has advocated them most warmly and perseveringly. The fact of the great and extreme danger of this condition has always been recognised; but it is only now, when the effect of agents on the heart is being investigated, that a ray of real light is illumining the question. This use of agents affecting the heart is of the greatest importance, and is one of the great questions of the future. The effect of digitalis on the right ventricle in acute distension of the right side in cardiac asthma has inspired me with hope in the treatment of this condition when arising in the course of acute affections. It is, however, a question of fact, not of theory. But a man slings no worse for having a target to aim at, and a rational comprehension of what we stand in need of, and of the exact action of the agents we employ, will assist us in our efforts. The practical success of these efforts can alone tell us unmistakably what is their real value. As in the treatment of chronic cardiac affections, no attempt is being made here to extol digitalis as possessing powers either unique or peculiar to itself. It is merely the most active and best known agent of this class as yet. In time we may find agents more powerful and rapid in their action, but at present we can get results from it that we cannot get from other agents.

[To be continued.]

**ERRATA.**—In the portion of the Essay which appeared in the JOURNAL of July 8, the following errors require correction. Page 27, column 2, twenty lines from bottom, for "sufficient," read "insufficient." Page 28, column 1, line 29 from bottom, for "palpitation," read "pulsation." Page 28, column 2, line 36, read "inhibitory action of pneumogastric plus the vis inertie of the blood." Page 29, column 1, line 10, for "junction," read "function."

# ON THE ELEMENT THAT KILLS IN CHLOROFORM, AND OTHER ALLIED CHEMICALS.\*

By J. D. BROWN, F.R.C.S.Eng., Haverfordwest.

OF all deaths, the quickest are those which follow the total arrest of circulation, where the action of the heart is first stopped. Next in rapidity are those that follow the total arrest of respiration. Death from prussic acid is a fearful example of the first; from drowning and strangling of the second. By prussic acid, death is instantaneously produced; in drowning and strangling, life is never prolonged beyond three minutes. Death from heart-affection is apparently easily explained; but why die from the exclusion of air? Let us imagine a person in full vigour and life, brought up dead from the water. Not a finger has touched him; not a drop of his blood has been shed; no poison has polluted his blood; yet he is dead, and three minutes ago he was full of lusty life. Why has he died? His organisation is still perfect. The reply, I expect, is, that he died because there was no arterial blood to circulate, oxygen having been excluded long enough to kill. In heart-disease the answer will be, that there was no heart-power to circulate the blood, although it was still arterial and pure. All this is plain enough.

We will now take up chloroform, ether, olefiant gas, and alcohol, with their varieties, in which I shall include all the compounds of carbon, whatever name may represent them, such as chloral, etc. Those chemicals are introduced into blood either as liquids or as gases; it matters but little now. In considering their chemistry, we find them richly charged with carbon in subtle solution. The little oxygen, hydrogen, or chlorine, that they contain, simply play the part of solvents to the carbon, and, as far as killing goes, can play no part.

There are two elements brought into play in their application; viz., the introduction of carbon, and the gradual exclusion of oxygen and nitrogen, carbon being retained on the one hand whilst it is being introduced on the other.

By excluding air, we can arrive at death without the aid of any other agent. By introducing carbon, we can reach the same point without calling upon strangling to help us. This is precisely what we accomplish in giving any of those subtle solutions of carbon, either as liquids or as gases. We gradually exclude the air and as gradually introduce the compound till we reach a given point, at which the blood is fully saturated with it, the agency of those two powers being put into force. It matters but little how we effect our aim; all that is wanted to complete our object is carbon, in sufficient quantity to overpower the brain and its functions. Drowning and strangling would answer our purpose quite as well as any of the chemicals in use, only we cannot as yet manage such dangerous agents with as much safety as we could wish. Moreover, they are painful modes, and never likely to be employed.

Of all our agents the pleasantest is chloroform, which, whilst killing, indulges the victim with the pleasant delusions of a happier life, and engages the respiratory organs at the same time in their usual work; thus throwing the whole living system off its guard, which, although apparently rejoicing in life, is in reality slowly dying. This is truly a happy death. The introduction of any of these compounds through the stomach produces the same effects.

Alcohol and chloral are well-known agents, capable of intoxicating and even killing by introducing carbon too suddenly and in excess. To remove their effect, oxygen must be called to our aid, which, gradually combining with the elements of the intoxicating substance, at last expels the overcharge in the form of carbonic acid, water, etc.

Having exhausted the compounds of carbon, and proved their terrible powers of stupefying and killing, we shall take up those possessed of the same power, and which yet contain no carbon. This is a paradox. Here, you will say, a difficulty arises, a barrier rears its head, over which one will not very easily pass. I can see none. We have looked on the fearful rapidity with which drowning and strangling kill. In what does their power consist? Simply in excluding air. We give a gas, such as nitrous oxide, nitrogen, or any other respirable gas—even hydrogen, and we will not even despise carbonic acid—the results are precisely the same; they kill with a rapidity that might be measured by the quantity of air allowed to mix with the gas used—in fact, we amuse the lungs and throw them off their guard whilst preventing the oxidation of the circulating carbon. This is much more pleasant than drowning, but equally fatal.

In nitrous oxide and carbonic acid we have compounds satisfied with their chemical conditions; therefore, neither the carbon nor oxygen are brought into play. They simply exclude atmospheric oxygen, thus

leaving the "killing" to the accumulating carbon. Flame, in ceasing to live in carbonic acid, simply dies for want of oxygen, not because carbonic acid is present, which, if it were to decompose, would yield sufficient oxygen to maintain combustion. An animal perishes in carbonic acid for the same reason. Chloroform has no advantage over carbonic acid except that its carbon is probably not free: I say probably, as there is no certainty.

*Cause of Death.*—It is not the detention of carbonic acid that kills, but the presence of carbon in some peculiar state, and unoxidised. The small quantity of carbonic acid which the last inspiration creates, even if taken up by the blood and not imprisoned in the air-cells, would be too little to kill, granting it had the power. Death is really caused by paralysis of the heart. In every instance of death in rabbits, the circulation first failed, beginning in the ears; danger was always plainly visible there; and when chloroform was further given to the complete arrest of circulation, death always ensued. On *post mortem* examination, the heart was found to beat, but not with sufficient vigour to empty its chambers. No blood seemed to pass through the lungs to the left chambers. There was an idle action, simply from the fact that the blood went home to die—viz., to the venous system, whose head-quarters is the right side of the heart and lungs. The last inspiration, shallow and superficial as it is, may be taken as a measure of the last stream poured out from the left ventricle to complete the circle for the last time, and then to stop for ever. The heart fails, because highly carbonised blood cannot maintain the vigour of the nervous system. The moment circulation ceases, respiration comes to a dead stand; to recommence the old work, circulation must take the initiative; respiration follows. This is the ordained order. With stagnant blood there can be no breathing. A newly born child breathes because his blood circulates: no human power could command a single breath had that function entirely ceased.

We now can understand why artificial respiration so often fails: in truth, we begin where we ought to end. Blood can only be oxidised in circulation; no amount of oxygen could tell upon the small quantity stagnant in the lungs—a proportion infinitely too small to rouse the nervous system even were it to move forwards. The first step towards life the heart must make; the second the lungs will take.

*Indications of death* are pallor and white lips; circulation has failed or is failing; a flushed or dark countenance is safe. Breathing you need not notice; it cannot go wrong. As long as the circulation is right, the first step to death is made by the circulation, the second by the respiration.

How to avert the impending death is the next question. There may still be a little arterial blood in the lungs and left side of the heart. There is just one chance: pour it into the brain by hanging the head down. If the brain respond, all is safe; the heart resumes its labours and the lungs answer to the call; and, unless we succeed in rousing the brain by the little arterial blood which the vessels may still hold, the case is hopeless.

It is impossible to manufacture arterial blood without oxygen; and it is not possible to get air to tell upon the whole volume of blood unless we can insure its circulation; and it cannot circulate without the heart's permission, and the heart will not act till the nervous system is able to command it, and until the blood gets rid of its overcharge of carbon. Artificial respiration is useless, and is a loss of time till the circulation resumes its labours.

Dragging out the tongue is an idle occupation; the mouth is not the passage for air. The glottis cannot be closed by a dead tongue and retracted epiglottis. The only instances of its closure are attended by congestion of face and brain, and not by pallor and empty vessels. Observe the face in epilepsy, in drowning and strangling, convulsions, stammering and choking from spasms, or by intruding morsels or liquids. The glottis is never closed, only whilst swallowing; no amount of stupor shuts it, and even in death it is always open; in fact, that is its normal condition, excepting in those diseases just named.

To me it is a question yet to be decided whether we could not shorten convulsions by keeping open the glottis if means could be devised. Stammering is always relieved by preventing its spasmodic closure, by keeping a marble in the mouth, by drawing, or by intonation of speech, as singing or reading poetry.

*SUMMARY.*—No time should be lost in artificial respiration, dragging out the tongue, etc.; but the brain should be roused by hanging down the head. There can be no harm in artificial respiration; it may be carried on at the same time. The cases appended all prove the value of this plan. It is also applicable to drowning, and to all the other causes of death just enumerated.

I append a few cases illustrative of the treatment recommended.  
CASE I.—A stout woman, aged 50, had her breast removed for cancer. Whilst we were securing the arteries, the circulation suddenly

\* Read before the South Wales and Monmouthshire Branch, July 5th.

stopped. She was to all appearance dead—no pulse, no breathing, no colour, but a ghastly white. At this critical moment I struck away all the pillows, and, with aid, laid her on the floor, her head lower than her body. Her lips became red, and in time she breathed, and by degrees recovered. There was no attempt at artificial respiration, nor was the tongue drawn out.

CASE II.—A young and healthy peasant girl had her leg amputated, to improve a bad stump left by mortification of her foot and lower third of leg, caused by typhus fever. We were dressing it, when suddenly bleeding ceased. She had been neglected by the chloroformist, who left the handkerchief too near to her nostrils. She was breathless, pulseless, and pallid. Her head was raised on a block and pillow for the operation, which I struck boldly away; her head fell with an audible noise on the table; at that moment the lips reddened, the face flushed, she breathed, and was safe.

CASE III.—A lady, young and healthy, took chloroform to have a tooth extracted. Pallor at last followed, accompanied with the usual signs of death from chloroform. This was early in my experience of chloroform, and I was much frightened. She was laid down, her head lowered, and by and bye her lips showed signs of life, breathing returned, and she was saved.

CASE IV.—A man aged about 56, delicate, and worn by long suffering, had his thigh amputated. Whilst the wound was being dressed circulation ceased, and he was apparently dead. His head was hung down over the table, and he soon recovered like all the others.

CASE V.—An infant, whilst under chloroform for the removal of a nevus, became alarmingly pale, and apparently died. So much had been said about artificial respiration and dragging the tongue out, that we tried it, and thereby lost time; it failed entirely; we then resorted to our old plan. The child was literally hung upside down, till the lips grew red, and all was safe.

## CLINICAL MEMORANDA.

### SUDDEN DECREASE IN THE FREQUENCY OF THE PULSE DURING DISEASE AS A SIGN OF APPROACHING CEREBRAL COMPLICATION.

DISEASES of the brain, from the insidious manner in which they often approach, and from the great difficulty which exists of recognising them in their earliest stages, together with that of making an accurate diagnosis, even when we know them to be present, demand very close and careful observation on the part of the physician. I wish, therefore, to draw attention to a point which I observed in the three cases related below, viz., that during the course of diseases in which the pulse usually ranges high, a sudden diminution in its frequency took place some time before brain-complication could be recognised by any other signs. I have no doubt this may be known to many members of the profession; but, from the fact that it is not mentioned in any of the text-books on the subject with which I am acquainted, I think it has not been taken as much notice of as it deserves, for I consider that it will in many cases serve as a very material aid towards a prognosis.

In January, 1868, I was asked to prescribe for D. M., a letter-carrier, aged 45, who had for some time been labouring under an attack of pulmonary phthisis. The disease ran its usual course for some time, cavities having formed in both lungs, until suddenly on the 20th of June the pulse, which up to this had ranged from 100 to 108, fell to 74, and continued between 74 and 80 until the 16th of November, when headache followed by squinting set in. Coma and death closed the scene.

The second case was one of strumous diarrhoea in a child, aged 8, in which the pulse was constantly above 100 until two days before the manifestation of the symptoms of meningitis, when it fell to 76.

But the case which made most impression on me was the following. On the 29th of last month I received a note from a medical man requesting me to visit his child, aged 7, whom he had sent to Newcastle for change of air, and of whom he gave the following history. In January last he had measles; when recovering from this disease, he was attacked by gastric fever, which confined him to bed for five or six weeks; on partially recovering from this he had an attack of bronchitis, and now his chief disease was gastric irritability. On my visit next day I met his father, who told me that a sudden change had taken place in the little patient's pulse: during his other illnesses it had always been above 100, but on the previous day he found it reduced to 82. Having the two previous cases in mind, I told him that we must examine the patient carefully for head-symptoms. We found him lying quietly, breathing naturally, and not showing any sign of brain-disease except the vomiting, which appeared to be gastric. Next day, under the use of fluid magnesia and milk, the vomiting had disappeared. The pulse was 82,

regular and full; the tongue still coated. On the following day the same state of matters existed, except that the patient appeared more listless and complained slightly of the light, but his pupils acted naturally. On the following morning at two o'clock delirium set in, followed by coma, and death on June 12th.

I do not mean to convey that we can always connect the slowness of the pulse and the cerebral disease as clearly as in these cases, but I am convinced that in many cases the symptom will prove to be all that I claim for it, *an aid to prognosis*.

GEORGE GRAY, M.D., Castlewellan, Co. Down.

### HERPES FRONTALIS, GIVING RISE TO CONTAGIOUS ERYSIPELAS.

A MAN aged 51 was admitted into St. Mary's Hospital on June 28th. A week previously he had begun to have a feeling of fullness in the head, and four days before an eruption had appeared on the right side of the forehead and head, attended with severe pain. The affected part then began to swell and become red; and, on admission, the head and face presented a marked erysipelatous appearance, especially on the right side; both eyes were swollen up; there was still much pain in the head; no high fever; temperature, 98.2 deg. The case was one of herpes frontalis, but complicated with so much erysipelatous inflammation of the affected region and surrounding parts as to obscure the real character of the attack. The redness and swelling gradually subsided, leaving scattered scabs over the right side of the forehead and scalp, as far back as the parieto-occipital suture, which, on falling, exposed small deep clean cut, irregular cicatrices, perfectly characteristic of herpes. Fortunately, the nasal branch of the ophthalmic nerve had not been affected, and thus the eye was spared; a single minute vesicle only making its appearance at the lower edge of the cornea.

The interest of the case, however, consists in the fact that erysipelas spread from the patient in the ward. This conclusion, at any rate, seems to be warranted by the fact that, whereas there was no erysipelas in any part of the hospital, nor had been for some time, three cases appeared in the wards within a few days of this man's admission. Apparently, therefore, herpes frontalis (an eruption consequent upon nerve-disturbance) gave rise to inflammation of an erysipelatous character, which was communicated by contagion to others—that is, there was generation of a communicable or contagious disease. It is worthy of remark that the time in which the herpes ran its course was not prolonged. The treatment consisted of good feeding and large doses of muriated tincture of iron.

I remember to have seen the skin supplied by the supraorbital branch of the fifth nerve, on one side remarkably atrophied; it was thin, shining, and almost devoid of sensibility, the change being attributed by the medical attendant to erysipelas. Cicatrices, such as those described above, however, showed it to have been consequent upon herpes frontalis; and it is not improbable that a similar result may follow in this case.

W. H. BROADBENT, M.D., Physician to St. Mary's Hospital.

## REPORTS

OF

### MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS OF GREAT BRITAIN.

#### NOTES ON THE TREATMENT OF GANGLION IN THE SCOTCH HOSPITALS.

EDINBURGH ROYAL INFIRMARY.

Mr. SPENCE long since abandoned the old plan of bursting or breaking up the swelling by force; it almost uniformly failed to effect a cure. The cyst gave way at its weakest point, and the contents were diffused, and the tumour disappeared at the time; but the irritation produced seldom sufficed to obliterate the secreting cyst, and the swelling soon reappeared. Mr. Spence's general procedure in the smaller swellings (as at the wrist) is to use a strong double-edged needle (an old-fashioned cornea-needle), introduce it subcutaneously into the cyst, and move it freely about in all directions, so as to tear up the cyst as completely as possible; he next applies a firm compress over the part for a day or two, and then a fly-blister is applied. This method Mr. Spence finds sufficient in ordinary cases. In larger cysts, or where the contents are fluid (as in those connected with the hamstring tendons in the popliteal space), he draws off the contents with a trocar and cannula, and injects tincture of iodine. This method rarely, if ever, fails in such cases; but it is not generally applicable, or rather very rarely

applicable, to the ganglia at the wrist, the contents of which are too viscid to pass out by any cannula of such a size as can be used in these smaller swellings. He has, however, used it successfully in a few cases. When the cyst is very dense, and its form and connexions are tolerably well defined, Mr. Spence dissects the swelling out as a whole; or, if he find that its deeper attachments would involve much dissection, he removes as much as possible of the projecting portion of the cyst, and applies iodine or nitrate of silver on the remaining cystic surface. If the superficial incision be free, and undue manipulation be avoided, it is wonderful, Mr. Spence has observed, how little irritation follows, even in cases where we are obliged to leave a part of the cyst. In many cases, the cyst is easily removed entire. He lately removed a large ganglion connected with the inner hamstring muscles from the popliteal space. It was of the size of a very large orange or small melon. He has not yet had time to examine its interior, but it was the largest he had yet seen.

Dr. GILLESPIE, in the smaller tumours, first tries to burst them by pressure with the thumb; and, if that succeed, he applies a well graduated compress, which rarely fails to effect a radical cure. If the thumbs fail, he uses an exploring needle and cannula, squeezes all the fluid out, and then applies a blister and compress, which almost invariably succeeds in obliterating the sac; but, if the fluid should reaccumulate (a very rare occurrence), he either injects tincture of iodine, or lays the sac freely open. He has tried wire and thread setons with success, but prefers the methods of treatment indicated above. In the larger ganglia, such as those affecting the wrist and palm, if of long standing, Dr. Gillespie has found nothing so effectual as laying them freely open, using antiseptic precautions and dressings. In some large, very fluid ganglia, he has tried evacuation of the contents by a hydrocele trocar and cannula, and then applying a blister or injecting iodine; and has succeeded in some cases in obliterating the sac, but just as often he believes he has had to follow up that treatment by fully laying open the anterior wall.

Dr. PATRICK HERON WATSON, in cases of ganglion, prefers forcible disruption of the sac by pressure with the thumbs, and firm friction of the skin against the parts beneath once each day for a week thereafter. If the sac be too tough to yield in this way, he employs puncture of the sac with a broad-bladed needle beneath the skin, followed by similar dispersive friction from day to day. In these cases, where there is an after-tendency shown to obstinate reaccumulation, he employs blistering with cantharides. In the special form of bursal tumour occurring beneath the annular ligament of the wrist, Dr. Watson prefers opening the sac freely above the annular ligament, squeezing out the melon-seed-like bodies, and closing the cutaneous wound with sutures. He places the hand and forearm in semiflexion upon a splint, and treats the wound with muslin soaked in alcoholic solution of pitch which has been allowed to dry before its application. Dr. Watson never now finds it necessary to divide the annular ligament, as used to be done by Mr. Syme. The success of this plan of treatment depends on completely emptying the sac and obtaining primary union.

Mr. ANNANDALE treats the simple ganglia met with over the dorsal aspect of the hand and foot by endeavouring to rupture them with the thumb; and, if this succeed, he applies a firm pad over the part for some days. If they will not rupture by external pressure, he opens the cyst subcutaneously with a fine tenotomy-knife, presses out the contents, and then applies a blister, followed by pressure with a pad. The ganglia containing seed-like bodies, usually occurring on the palmar surface of the wrist, Mr. Annandale treats by making a free incision into the sac, squeezing out all the contents, and dressing the wound carefully according to the antiseptic method. The chronic enlargement, with effusion of the bursal cysts over the patella, olecranon, and other bony prominences, he treats by a limited incision into the sac, and the introduction into the wound of a small piece of lint or other cloth soaked in carbolic oil, one part of the acid to ten of oil, which is removed at the end of twenty-four hours, the wound being then dressed with water or other simple dressing.

Dr. JOSEPH BELL's treatment is the following. For simple ganglion on the extensor surface of the hand and wrist, he first tries bursting by pressure (not by blow), followed by a blister. If pressure fail to rupture the sac, he punctures it freely subcutaneously, and squeezes out its contents into the cellular tissue; and then blisters, with firm compression by pad and bandage for a week or two. If this fail to cure, from the thickness and age of the cyst-wall, he excises the whole by free incision, and has had no bad effects from this. He never uses the seton, which is, he thinks, apt to cause suppuration in the sheath of the tendons. For compound ganglion in connexion with the flexor tendons, Dr. Bell has once or twice succeeded in effecting a cure by repeated blistering, but generally finds it necessary to make a free incision, which must include the annular ligament; he then squeezes out all the

melon-seed bodies which the cyst contains, and dresses the cavity with lint, so as to obtain healing of the cyst by granulation. If the incision be managed with antiseptic precautions, so as to prevent putrefaction, the cure is rapid and almost painless.

#### GLASGOW ROYAL INFIRMARY.

Dr. EBEN WATSON, when the ganglion is small and cystic, as it is usually on the back of the wrist, practises subcutaneous section of the cyst, allowing the fluid to pass into the areolar tissue. Moderate pressure is then applied to facilitate absorption; and, if this be slow, a blister may be used. In the more extensive cases, in which the sheaths of tendons are greatly dilated, as in the palm of the hand, he would pursue a similar treatment, and believes it would be successful. He once performed the free incision of the sheath and annular ligament, as recommended by Mr. Syme; but the patient nearly lost her life by reason of the violent inflammation of the areolar tissue of the whole arm which followed. If such a case presented itself to him now, and if subcutaneous section, in which he has great confidence, had failed, he would make one free incision above or below the annular ligament, and dress the wound carefully with spirituous solution of carbolic acid—of course, after emptying the sac. Dr. Watson's experience leads him to fear too much inflammation in the dilated sheath after operative interference, rather than too little; therefore he has not had occasion to use setons or iodine injections. He would rather not advise either of them.

Dr. GEORGE BUCHANAN, when practicable, bursts small circumscribed ganglia on the back of the wrist forcibly with a book. Few resist that form of force; and when they do give way, as a rule they do not recur. Those only have resisted the blow which had been previously treated by puncture. A case which he had lately yielded to bursting, and disappeared, which had previously been treated by subcutaneous incision, and had returned immediately. Large bursæ, especially those containing cartilaginous seed-like bodies, he has treated by free incision antiseptically and subsequent bandaging.

#### ABERDEEN ROYAL INFIRMARY.

The treatment which Dr. FIDDES adopts with regard to ganglion on the wrist and hand is puncture with a grooved needle, pressing the fluid out of the sac, and afterwards applying constant pressure. Dr. Fiddes never saw any outward application, such as iodine paint, etc., do good.

Dr. ALEXANDER OGSTON always punctures with a very fine exploratory trocar, to make sure of the nature of the swelling. On two occasions, he found a minute chronic abscess on one of them, connected with a minute scale of necrosed bone, simulating ganglion at the ankle-joint. Having made sure of diagnosis, and allowed the puncture time to heal, an attempt is made to rupture the cyst and extrude its contents subcutaneously by pressure with the thumbs. If the cyst be thin-walled, this succeeds, and pressure usually completes the cure. If manipulation with the thumb fail, a puncture of small size, about an eighth of an inch long, is made through the skin and cyst-wall with a narrow-bladed knife, and the contents of the ganglion are emptied through it by squeezing. If, after this, the subsequent pressure and bandaging fail to prevent its return, at the repetition of the puncture a thread is introduced as a seton into the cyst. Ganglia in the popliteal region about the hamstring tendons are never to be rashly meddled with. In a patient shown Dr. Ogston by Dr. Manson of Banff, he found a ganglion beside the biceps tendon, evidently communicating with the knee-joint. This occurrence has been already noticed by German authors.

#### ST. BARTHOLOMEW'S HOSPITAL.

SINUOUS SINUSES OF THE THIGH CONNECTED WITH NECROSIS OF FEMUR OF OLD STANDING, DIAGNOSED BY THE "VERTEBRATED PROBE": REMOVAL OF SEQUESTRUM.

(Under the care of Mr. CALLENDER.)

The following notes have been taken by Mr. Young, house-surgeon.

About six years ago, A. R., aged 45, by occupation an omnibus-driver, first noticed some tenderness about the left gluteal region, which was followed by swelling, and ultimately by the formation of abscesses in the ischio-rectal fossa and middle of the back of the thigh, which broke about twenty months ago, and have been discharging ever since, despite treatment at various institutions. Several sinuses, with pouting granular orifices, occupied the left ischio-rectal region; and one sinus had its opening on the middle of the back of the left thigh. Into any of these a probe could be passed for some distance in the direction of the tuberosity of the ischium, but, owing to the tortuosity of the passages, failed to reach any dead bone. Dr. Sayre, who saw the case at a consultation on the 13th instant, remarked on the coincidence that it was in a precisely similar case that he first used his flexible probe in

America; and in the present instance this instrument traversed with great ease the winding course of the sinus until its point was distinctly arrested by bare bone.

On the following Saturday, Dr. Sayre being present at the operation, a free incision was made over the left tuber ischii; and a considerable portion of dead bone was removed from a cavity in the tuberosity, in which it was loosely contained. The sinus which traversed the thigh had followed the course of the muscles arising from the tuberosity.

### LEEDS GENERAL INFIRMARY.

#### RHEUMATIC PERICARDITIS, WITH EFFUSION: RECOVERY.

(With Clinical Remarks by J. D. HEATON, M.D., F.R.C.P.)

PATRICK McHALE, aged 21, a delicate looking, slightly built young man, who had worked in a flax-mill, was admitted with the ordinary symptoms of acute rheumatism. During the last six years he had had five attacks of the same complaint; the last, prior to the present attack, was about a year ago, from which, so far as he knew, he made a complete recovery. He had had no cardiac pain nor palpitation; had never spat blood nor had any habitual cough.

The present attack began about a fortnight before admission, the large joints, elbows, and knees, having become swollen and painful, this being accompanied with a considerable amount of indisposition. On examination, on the day after admission, besides the local affection of the joints, he had a good deal of inflammatory fever, and complained of pain in the cardiac region; there was a loud double murmur at the base of the heart; also, a double murmur at the apex, less pronounced, both these sounds being less audible at a point intermediate between base and apex; there was considerable excitement of the heart's action; pulse frequent and jerking. A purgative pill, and the alkaline saline mixture which I ordinarily prescribe in cases of acute rheumatism, with a proportion of tincture of digitalis, were prescribed, and a sinapism applied over the heart. In two days he was propped up in bed, and had an anxious countenance and moaning voice, but made no complaint of breathlessness. There was much pain at the heart, whose action was excited; pulse 120. The pain in the joints was no longer noticed. The double murmur heard over the apex of the heart was now obscure, being only audible when the patient sat up. Percussion over a space of three inches in perpendicular measurement, from an inch above the nipple to two inches below it, and of two inches wide, measured from the median line under the sternum to the left, gave a dull stroke-sound; above this was the ordinary pulmonary resonance; below it, the tympanitic sound of flatus in the stomach. Change of posture had little effect upon the limits of the non-resonant area. In addition to the mixture already prescribed, a powder containing six grains of compound ipecacuanha powder, three grains of antimonial powder, and a grain of calomel, was now ordered to be taken every six hours; and a blister was applied over the heart.

Three days afterwards, the unfavourable symptoms were still progressing. The double aortic murmur was loud and sonorous, and altered in quality; the sound at the apex was obscure. The dullness over the left front chest had extended upwards to the third rib, and laterally to the right, beyond the median line; there was, also, an appreciable deficient resonance over the corresponding surface posteriorly. The patient seemed ill and distressed, but made no complaint of oppression to the breathing. Decubitus was entirely on the back; respiration diaphragmatic. The same treatment was continued. From this time, the symptoms began to improve. In two days, the patient looked and felt better; he had no constant pain; the upper limit of dullness on the front chest had fallen an inch and a half; the cardiac sounds at the apex were more audible; the aortic murmur at the base was less loud, and was altered in character. The left back was more resonant. Four days afterwards, gradual improvement was recorded; both the voice and countenance were better. The pulse was below 90. The area of complete dullness on the front of the left chest was still contracting. There had been no change in treatment; neither the gums nor the breath showed any evidence of mercurialisation. A second blister was applied, to promote absorption.

Without going into farther details, the patient gradually recovered; he was able to lie on either side, and soon began to leave his bed. Iodide of potassium was substituted for the previous treatment, and his diet was improved. The extent of cardiac dullness contracted to its normal measurement; the heart's action became quiet, but the aortic murmurs at the base of the heart were permanent. The rheumatic pains left him, and he was discharged convalescent.

REMARKS.—Some time ago, I drew the attention of my class to a case of hydro-pericardium, without inflammatory symptoms, which proved suddenly fatal (see BRITISH MEDICAL JOURNAL, July 2nd, 1870, p. 8). We have here a case of pericarditis with effusion, having a more favourable

result, and presenting several points of interest for our consideration. When the patient was admitted for the rheumatic complaint, there were no signs of pericardial effusion; and the fluid was again absorbed prior to his discharge; so the whole course of the rise, progress, and decline of the affection has taken place under our observation. We will consider briefly the principal points of diagnosis involved in this case, the treatment, and its results.

On the first examination of the heart, a double aortic murmur was heard at the base of the heart, of a blowing character, and distinctly valvular. A double murmur was also heard at the apex, synchronous with the former, and not very clearly distinguishable from it. Some of my class thought that the sounds heard at base and apex had the same origin, any variation in their character being due to the different auscultatory sites. But as the sounds faded away at a point intermediate between base and apex, we came to the conclusion that each sound originated at the point where it was most audible.

I have said that the sounds heard at the base of the heart were distinctly aortic and valvular; the character of the pulse corresponded with this conclusion. But a valvular murmur may either be a chronic condition, the result of some permanent lesion, or it may be the result of recent and existing inflammatory action. In a rheumatic patient who has had several previous attacks of the complaint, it is by no means always easy to decide between these possibilities, from the *auscultatory signs* merely; we must take into account the *general symptoms*—pain, fever, excited action of the heart, sense of oppression. It is safer to suspect endocarditis erroneously, and treat accordingly, than to run the risk of casting an undeserved slight on an inflammatory murmur, as though resulting only from an old valvular lesion. In the present instance, the cardiac pain, the excited action of the heart, and the general symptoms evidenced an inflammatory affection of the heart; and the variable quality of the aortic murmur left little room to doubt that the inflammation was partly endocardial, involving the aortic orifice and its valves, though not improbably complicated with pre-existing lesion of the aortic valves.

The double murmur heard at the apex was a gentle superficial-seeming sound, synchronous with the ventricular systole and diastole. When first heard, it was supposed to have its origin in the mitral aperture; the subsequent history of the case clearly shows that it was a pericardial friction-sound. It is not always possible to pronounce with certainty whether a given murmur is endocardial, or the result of pericardial friction; either sound may be double or single, its quality may be described as blowing or rubbing, and either may have the apparent character of superficiality. Pericardial murmurs, like endocardial, may be heard either at the base or at the apex; as to which of these is the more common seat of pericardial friction-sounds, there is some difference of opinion. Trousseau says that "in pericarditis the friction-sounds are usually heard around the base of the heart." The result of my own observation is that the apex of the heart is the more common seat of friction-sounds. Such was the fact in our case. The apex performs more extensively those movements by which the sound of friction is developed; it impinges with some force against the wall of the chest, gliding over the pericardial sac with each ventricular systole, and receding during the diastole. On the other hand, the base of the heart remains more permanently in apposition with the pericardial walls; whereas when effusion commences, the apex is speedily immersed in fluid, through which it moves without friction. Friction-sound must therefore first cease at the apex; but, at whichever place developed, it is a sound which is generally heard rather extensively, being conducted along the solid walls of the chest. As the effusion increased, the friction-sound diminished, and could only be developed by making the patient sit upright, by which the heart was brought into proximity with the front of the chest; and, corresponding with this, was the other result of the effusion, viz., the gradual extension of the area of dull stroke-sound, as described in the report.

Sometimes the diagnosis is doubtful between pericardial and pleural effusion; but the circumscription of the effusion within the known limits of the pericardium, and its fixed position, though the patient's posture was changed, as well as the markedly cardiac character of the other symptoms, established an unhesitating diagnosis of pericardial effusion in this case. During the progress of recovery, the amelioration of the general symptoms and the gradual subsidence of the physical signs accompanied each other *pari passu* with remarkable exactness.

In the treatment, we had to encounter the rheumatic diathesis, as well as the serious local complication of the heart. For the first, our ordinary plan of treatment was adopted, viz., a brisk purgative in the first place, and an alkaline saline, containing in each dose fifteen grains of bicarbonate of potash. For the second, tincture of digitalis was added to the mixture; a combination of small doses of calomel, antimony, and opium, was given every six hours for nearly a fortnight, no salivation

being produced thereby, which is remarkable; and two blisters were applied in succession over the heart. When all active symptoms had disappeared, and absorption of the effusion was in progress, iodide of potassium in some bitter infusion was substituted for the previous medicine, to expedite the process and restore strength. Not much comment is needed upon this plan of treatment. The alkaline treatment of acute rheumatism is that which is most generally approved, and which I always adopt, preceded by an active purgative to clear the *primæ viæ*, and promote the elimination of impurities from the blood. You are well aware that the free use of mercurials is no part of my ordinary practice; but I have not altogether renounced the belief (which was almost universal in my younger days) in the antiphlogistic value of calomel, especially to restrain the formation of inflammatory products, or promote their removal where their presence constitutes the essential danger. The advantages and disadvantages of irritation of the surface by blisters, to counteract inflammatory action in internal organs, has been of late much debated; our time will not allow a discussion of the *rationale* of this treatment, which has been brought before you on other occasions. I shall only say that, empirically, I have constant evidence of their utility. The treatment of the local articular inflammations of acute rheumatism by blisters is a recent practice strongly recommended; and analogy suggests, as experience confirms, that equally beneficial results may follow the same treatment of the serious inflammation of the membranes of the heart of a rheumatic origin. The treatment of the stage of convalescence by iodide of potassium and vegetable tonics, is my customary practice in this stage of acute rheumatism, which I believe to be attended with much benefit in such, as it is also in chronic rheumatism.

There was a period of one or two days when our patient's distress was great and the symptoms of immediate danger were sufficiently serious; and I then began to discuss the expediency of seeking to give relief by tapping the pericardium. But the next visit witnessed the commencement of a favourable change and I was relieved from the anxiety with which I should have advised this operation; for, although I recognise its importance and success in occasionally saving a life otherwise seriously endangered, I cannot overlook the possible risk of puncturing the heart, or of arousing fresh inflammation in so vital a part. In the criticisms which my colleague Dr. Allbutt published on my remarks on my previous case of hydropericardium, he considers the operation of tapping the pericardium, if properly performed, as wholly devoid of serious risk, and he adduces a conversation with Trousseau in support of his views. Having never been in the society of that eminent physician, I can only quote his published and perhaps more carefully considered judgment, that "one never without trembling decides upon performing" the operation; and, again, that "paracentesis of the pericardium is only indicated in cases in which life is threatened by the extent of the effusion. The occasions in which it ought to be resorted to must always be of rare occurrence." (See Trousseau's *Clinical Medicine*, vol. iii, pp. 365 and 395.) I consider this to be a satisfactory case in its progress and immediate results. In rather less than three weeks we have witnessed the formation and the reabsorption of a considerable inflammatory effusion in the pericardium. Nevertheless, though we have heard nothing of our patient since he left the Infirmary, my fear is that, although he has thus escaped the immediate danger with which he was threatened, and has hitherto made a good recovery, he will not altogether emerge from the encounter finally unscathed.

Besides the probability of pre-existing injury to the aortic valves previously noticed, there is the likelihood that the collapsing pericardium will contract adhesions with the heart, by which the freedom of its action will be impeded; and that secondary changes will result, varying according to the extent of the adhesion and the more or less organised character of the fibrinous material by which the attachment is effected.

Thus, hypertrophy may be occasioned by the exaggerated efforts of the heart, the freedom of whose movements is restrained by the embraces of an adherent pericardium; and, although such hypertrophy may be regarded as a compensatory effort of nature, yet no such perfect equilibrium of force and resistance will be obtained as that which enables a sound heart to work without perceptible effort throughout a lifetime.

In other cases, a compression of the heart has been produced by the contractile force of a layer of cacoplastic lymph, which, like the cicatrix of a burn, gradually contracts with a slow but irresistible force. But in a case like ours, of speedy subsidence of the primary inflammation, this effect is not likely to be the result.

In any case, it is to be feared that embarrassment, more or less, to the action of the heart, will make itself felt in future years, as a consequence of what has now occurred.

THE Subscriptions to the Association for the year 1871 became due in advance on January 1st. All which are not already paid, should be forwarded to the General Secretary, Mr. T. Watkin Williams, 13, New Hall Street, Birmingham; or to the Secretaries of Branches.

## BRITISH MEDICAL JOURNAL.

SATURDAY, JULY 22ND, 1871.

### SPIRITUALISM TESTED.

#### II.

WE have already pointed out that sleight of hand is a very important factor in the production of spiritualistic manifestations. In the present article, we propose to show that a particular nervous temperament and certain forms of disease, as hysteria, catalepsy, and ecstasy, serve to explain many of the phenomena which credulous believers in the new faith ascribe to non-natural agencies.

Before taking up this subject, we may, however, briefly notice certain known physical forces to which some persons, who hardly go the length of adopting the spirit-hypothesis, refer the peculiar manifestations that are occasionally exhibited at the *séances* presided over by professed mediums—namely, animal electricity and magnetism. All our knowledge of animal electricity tends to show that it does not essentially differ from the galvanism developed in the laboratory by chemical action; and hence the idea that tables can be moved, rappings produced, or visionary hands made to appear, by this agency, is simply absurd. It has been held by some, especially the Baron von Reichenbach and his followers, that magnetism—a force which is now proved to be correlative with electricity—resides in the body; and that some persons are specially sensitive to the influence of the magnet and to the magnetism evolved by other persons. There is undoubtedly a certain amount of fact in the Baron's curious investigations,\* although most of his experiments have no other foundation than that property of the human mind which causes it to be subjectively affected by suggestion—a point to which we shall immediately recur. Dr. Hammond, to whom we have already expressed our obligation for the materials on which these articles are based, while fully admitting that "certain very obvious symptoms are induced by the application of a magnet to the body, and that the lower animals and even plants are indubitably affected by its influence," adds that, "with all this, there is no proof that magnetism or the odic force is capable under any circumstances of producing the clairvoyant state, of moving tables, and of causing raps; or that any of the other more striking phenomena that are claimed for spiritualism can be accounted for through its agency."

Physical causes, calculated to increase the amount of blood in the brain, or to alter its quality, may give rise to hallucinations, which believers in the current delusion might naturally regard as spirit-visitations. Various narcotics, which induce these conditions in many persons, and pressure upon the jugular veins, sometimes produce a similar effect. A case is recorded in which a gentleman can always cause the appearance of images by tying his handkerchief moderately tight round his neck; and one figure, resembling Sir Walter Raleigh in features and costume, is always the first to come and the last to go. This figure imposes on the hearing as well as on the sight, and not only promptly answers questions addressed to it, but the replies are far more rational than those given by the evoked spirits of various eminent philosophers. How easily might a credulous person thus affected believe that he was actually conversing with the spirit of the real Sir Walter!

It is, however, to the operation of suggestion, which readily influ-

\* A full account of the experiments referred to may be found in his *Physico-physiological Researches on the Dynamics of Magnetism*, translated by Dr. Ashburner, and published in 1851. The first English notice of them was given in one of the earliest volumes of Ranking's *Half-yearly Abstract of the Medical Sciences*.

ences a large number of patients with diseases of the nervous system, that many, if not most, of the miracles and impostures of the spiritualists owe the success with which they have been received. The persons in whom this ability to be impressed by suggestions is present in the highest degree, are precisely of the same class as those who are most readily thrown into the hypnotic state (by Mr. Braid's method or otherwise) and those who are influenced by Von Reichenbach's odic force; and natural somnambulists (if we may use the term, in contradistinction to those in whom a similar condition is artificially induced) also seem to belong to the same category. In a very remarkable case recorded by Dr. Hammond—that of a young lady who, after suffering for some years from sleep-walking, could hypnotise herself at will by taking a philosophical book, reading and thinking of an abstruse passage, and then fixing her eyes steadily, but not directing them to any particular object—images suggested to her when in that condition could be immediately called up. For example, in reply to a question, "Where are you now?" she replied, "In New York"—which was the fact; but when she was told, "No, you are in a vessel at sea, and there is a terrible storm; are you not afraid?" she at once grasped as it were at the suggestion, and not only answered, "Yes, I am very much frightened; what shall I do? Oh save me, save me!" but wrung her hands, screamed with terror, and showed every sign of intense fear. On another occasion, her powers of vision when in the hypnotic state were tested by asking her to read a particular line from a closed book, to tell the time marked by a watch held to the back of her head, etc.; but, although she always made some answer, she was never right. The senses of touch and hearing were the only ones she appeared capable of exercising. If this young lady had been inclined to deceive, or had been under the control of designing persons, she would here unquestionably have been received by a large class as a medium of the first order.

Hysteria, in some one or other of its Protean forms, is doubtless the disease which more than any other furnishes the most abundant crop of fruit to the spiritualists. We will illustrate the close connexion between the disorder and the delusion by a brief record of two cases.

A married lady, before seeking professional advice, had for some months suffered from hallucinations of sight and hearing. She had merely to think of some particular person, living or dead, when she immediately saw his image; and he spoke to her, wept, walked about the room, or did whatever other thing she imagined. At first she fully believed that she really saw the spirits of the persons of whom she happened to think; but in the course of time she learnt to ascribe her visions to their true cause—disease. On examination, it was found that she had other symptoms of hysteria besides the hallucinations. There was hysterical paralysis of motion and sensation in the right leg, so that she could neither move it nor feel a pin thrust through the skin. There were tonic contractions of various muscles, and other symptoms indicating the true nature of her case. Under suitable treatment, she entirely recovered.

A servant-girl, residing in the family of Dr. Larkin (a weak-minded man in the opinion of his friends, although an experienced surgeon), declared that she was by turns under the influence of a good spirit called "Katy", and of a bad one whom she called the "sailor boy", who took great delight in swearing through her, and in uttering such profane language as he had formerly used on earth. After a time, a most singular and distressing phase of the affection supervened. Under the influence of the bad young sailor, the girl's limbs would be thrown out of joint in a moment, with apparent ease and no pain whatever. To reduce these dislocations was beyond the power, or at all events against the will, of her evil spirit; and her master was often obliged (it being just before the introduction of chloroform) to call in the aid of some of his professional brethren and two or three strong assistants. On one occasion, the knees and wrists were dislocated twice in a single day. She exhibited almost incredible feats of strength and agility; and there was such frightful contortion of the limbs, that "she became tied up with knots and coils which baffle all attempts at description."

Those who are familiar with hysteria will recognise it as fully in this second case as in the first; and yet this girl was not a patient, but a "medium"! The case is taken from Mrs. Hardinge's *Modern American Spiritualism* (1870)—an undoubted spiritualistic authority. Without referring to the hysterical epidemics of the seventeenth and eighteenth centuries—the Jansenist *convulsionnaires*, the nuns of Loudon, the victims of the witches of Salem, etc.—we find in all modern works on hysteria and in many on insanity (pre-eminently Calmeil's well known treatise) cases more or less closely resembling that of this unfortunate girl, especially in their immunity from pain, under circumstances that would occasion excruciating agony in persons of a normal constitution.

It may astonish many of the unhappy believers in this wide-spread delusion, to be told that a physician conversant with mental and nervous diseases can predict from their personal appearance with perfect accuracy the individuals at a spiritualistic meeting who, in the course of the sitting, will exhibit special phenomena. Nor are his powers limited to mere prediction. When the phenomena are of an hysterical class, and are not due to legerdemain, he can generally remove them by a judicious course of tonics.

Such are the principal arguments that may be adduced in evidence of the view that there is nothing in the so-called manifestations of spiritualism that may not be accounted for by the ordinary laws of Nature; and any experienced practitioner, who may be called upon to expose the fallacies of this comparatively new delusion, can modify them by illustrations taken from his own practice, so as to meet the special weaknesses of such of his patients as may be halting between two opinions. As we stated in the commencement of our former article, it is as useless and as hopeless to argue with a confirmed spiritualist as with a confirmed maniac.

Since the preceding article was written, Mr. Crookes, a distinguished Fellow of the Royal Society, the discoverer of the metal *Thallium*, and the editor of the *Quarterly Journal of Science*, has published a paper entitled "Experimental Investigations of a New Force", which in a slight degree bears upon the subject of spiritualism, in so far as it contains a history of certain experiments made on Mr. Home, who is, as our readers doubtless know, regarded as a powerful medium. According to Mr. Crookes, these experiments "appear conclusively to establish the existence of a new force in some unknown manner connected with the human organisation, which, for convenience, may be called the Psychic Force." This force seems to be powerfully developed in comparatively few persons, and it is more clearly manifested in Mr. Home than in any one else on whom experiments were made. Even in this gentleman it varies greatly, so that results obtained at one sitting might or might not be confirmed at the next. At the third trial, the first two sittings having been comparatively failures, the following remarkable phenomena occurred. A new accordion, purchased for the occasion, was grasped between the thumb and middle finger of Mr. Home's left hand, and inserted, with the keys *downwards*, into a wire cage, which was of such a height that, when pushed under the dining-room table, the intervening space was so small that the hand remained visible to those sitting on each side of him. The accordion was very soon seen to move about the cage, and to emit sounds, although the hand that held it remained perfectly still. The instrument was, in a subsequent experiment, "taken without any visible touch from Mr. Home's hand, which he removed entirely," and "floated about with no visible support inside the cage." He shortly afterwards re-inserted his hand, and took hold of the instrument, when it played a well known sweet melody—possibly "Home, sweet Home." Mr. Crookes convinced himself that Mr. Home was not moving a muscle while this tune was being played. The next experiment was more decisive and striking than those on the accordion. By gently placing his fingers on one end of a mahogany board a yard in length, which rested on a firm support, Mr. Home caused the other end, which was suspended horizontally by a spring balance attached to a tripod stand, to have an increased downward pressure varying from three and a half to six pounds. As

the slight pressure exerted by his fingers acted in a direction that would have caused the distant end of the board to rise rather than to descend, the effects that were produced could not be due to that cause. Regarding the nature of the force that is exhibited in these phenomena, Mr. Crookes thinks "it would be wrong to hazard the most vague hypothesis"; and Dr. Huggins, who witnessed the experiments, is equally cautious. "They appear," he observes, "to shew the importance of further investigation; but I wish it to be distinctly understood that I express no opinion as to the cause of the phenomena." We need scarcely add, that neither of these distinguished physicists has apparently the slightest leaning towards spiritualism.

#### REPORT OF THE CONTAGIOUS DISEASES COMMISSION.

THE Report of the Contagious Diseases Commission establishes some important facts. The charges of outrage and insult of modest women, of cruelty and tyranny, with which every platform in England has been made to ring, have completely broken down. Those who made them have either shrunk from repeating them where they could be sifted, or have brought them forward only to have them proved to be groundless. The sanitary effect of the Acts has been proved to be not less than we have alleged it to be on good medical evidence. The Commissioners relate that, taking the aggregate of twenty-eight stations of troops in the United Kingdom, at which the average strength amounted to 500 and upwards, the ratio per 1,000 of the diseased in 1865 was 120; in 1867, before the fortnightly inspections had commenced, except for a few months at Chatham, the disease had fallen to 86; it continued to decrease from 86 to 72 and 60, until it fell to 54 in 1870, when these inspections were generally established throughout the subjected districts. They have equally satisfied themselves that the Acts, so far from increasing, have diminished the amount of clandestine prostitution, and have conferred a public benefit in aiding public decency by the better conduct of the women in the streets. The "Curragh wrens" are no more; and these much abused Acts "have purged the towns and encampments to which they have been applied of miserable creatures who were mere masses of rottenness and vehicles of disease, providing them with asylums where their sufferings could be temporarily relieved, even if their malady was beyond cure, and where their better nature was probably for the first time touched by human sympathy."

As to the reclamation of fallen women under the Acts, it appears that, out of 9,688 women who have been registered under the Acts, 7,038 have been removed from the list, the largest proportion of them having left the district, and many having been restored to their friends. The inspector in the Devonport district states that his inquiries have quite satisfied him that no less than 90 per cent. of the women removed from the register have ceased to be prostitutes; and there have been removed from the streets and the houses of ill-fame some two or three hundred children between the ages of thirteen and fifteen.

Our readers will recognise in these conclusions of the Royal Commission a minute confirmation of every statement which we have ever made concerning these Acts. The particular point on which we have already several times expressed doubt is that which arrests the Commission. What is the urgency of the "antecedent moral objections" to a system of periodical inspections of dissolute women? It seems that many of them are accustomed to describe themselves as "Queen's women"; that a species of State recognition is held to be implied in these examinations—a grim and repressive proceeding enough, one would have supposed; and, on the whole, the Commissioners recommend that they be not enforced. It is to be observed that they do not face the argument that persons capable and likely to disseminate a pernicious disease ought to be subject to all possible restrictions. We should have liked to see them argue this question; but evidently they have on this point arrived at a compromise. We are not disposed to

say that it is an unwise one, although the conclusion is clearly not supported by adequate argument. Their recommendations are:

1. That the periodical examination of the public women be discontinued.
2. That every common prostitute found to be diseased after an examination by a medical officer, upon a voluntary submission or upon a magistrate's order, shall be detained in a certified hospital until she is discharged by a magistrate's order, or by the authorities of such hospital, provided that such detention shall in no case exceed the period of three months.
3. That in order to obtain a conviction under 29 Vict., c. 35, sec. 36, the Act of 1866, it shall not be necessary to prove that the owner or occupier of the house therein named had reasonable cause to believe that the prostitute was affected with a contagious disease.
4. That 32 and 33 Vict., c. 95 (the Act of 1869), secs. 4 and 5, be repealed.
5. That the Secretary of State for the Home Department be substituted for the Commissioners of the Admiralty and the Secretary of State for the War Department in the Act of 1866, and that the police employed in carrying the Acts into force perform their duty in uniform.
6. That the provisions contained in sections 11 to 21, inclusive of the repealed Act of 1864 (with an amendment of section 18 corresponding to the amendment proposed in section 36 of the Act of 1866), be extended to any place in the United Kingdom (except the cities of London and Westminster), from which a request for such extension shall be made, and in which proper hospital accommodation shall be provided.
7. That every keeper of a public-house harbouring prostitutes be deprived of his licence.
8. That every keeper of a common lodging-house harbouring prostitutes be subject to the penal clauses of the Common Lodging Houses Acts.
9. That the certificate of the Secretary of State under the 19th and 20th Vict., c. 69, sec. 6 (the Police, Counties, and Boroughs Acts), do certify that the third section of the Vagrant Act, 5 Geo. IV, c. 83, and the section of the Towns Police Clauses Act, 10 and 11 Vict., c. 89, relating to common prostitutes and night walkers, have been duly observed.
10. That 24 and 25 Vict., c. 100 (the Act to consolidate and amend the statute law relating to offences against the person), secs. 51 and 52, be amended by extending the age from twelve to fourteen years.
11. That girls under the age of 16 acting as common prostitutes be sent to a home or industrial school for a period not exceeding two years, if they cannot be otherwise provided for to the satisfaction of a magistrate.
12. That the Acts be partially extended to the metropolis.—This is the general report of the Commissioners, and represents a kind of compromise, from which those who desire to keep the law as it is, and those who wish to get rid of it altogether, dissent in separate memoranda.

FOUNDER'S day was celebrated at Epsom College on Thursday, July 20th.

THE out-patients' department of the Bristol General Hospital is to be enlarged, at an estimated cost of between £5000 and £6000.

THE ceremony of placing the memorial stone, on the occasion of the opening of the east wing and central building of the West London Hospital, was performed on Saturday last by the Duke of Devonshire, in the presence of a large assemblage. The hospital now contains one hundred beds.

THE colleagues of Dr. Sibson and Mr. Lane at St. Mary's Hospital have entertained them at a dinner on the occasion of their retiring by lapse of time from the active staff of the hospital and school, in which they served long, ably, and faithfully, and in founding which they took an active part.

THE English Ambulance in the Rue d'Aguesseau, Paris, which has been in full operation during both sieges of Paris, and has afforded much valuable aid to the wounded in Paris, under Dr. Cormack, especially during the second siege, is to be closed in a few days, and the patients who may remain are to be transferred to a house in the suburbs to which ample grounds are attached.

THE blue ribbon of Wimbledon, and indeed of rifle-shooting—the Queen's Prize—has this year been carried off by a son of Professor Humphry of Cambridge. He is an undergraduate of Trinity College.

#### THE HEALTH OF THE WIMBLEDON CAMP.

THE health of the camp has been unusually satisfactory during the week. There has been scarcely any diarrhoea, notwithstanding the great heat and consequent "refreshments". Only one slight case of sunstroke has occurred. A trifling wound from the splash of a bullet, a few cut hands, and a sprain or two, have also been attended to at the hospital.

#### SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.

AT a quarterly Court of Directors held July 12th—Dr. Burrows, President, in the chair—grants to the amount of £1,278 : 10 were made to fifty-five widows and forty-five children. Two widows and three children were added to the list; and the death of one recipient of grants was announced. Two members were elected; and five were proposed for election at the next court, to be held in October.

#### THE OBSTETRICAL SOCIETY OF LONDON.

AN excellent step has lately been taken by this Society in the appointment of a Committee, with Dr. William Squire as President, and Dr. Edis, 23, Sackville Street, W., as Secretary, to obtain systematic investigations into the temperature during pregnancy, parturition, and the puerperal state. The Committee has prepared a form for recording observations during these periods, which appear to include most if not all the points of importance to be attended to by the observer. Space is left for a short history of each case to be appended. These forms will be issued to all members of the Obstetrical Society, and to members of the profession who are willing to afford assistance to the Committee.

#### ST. MARY'S HOSPITAL MEDICAL SCHOOL.

THROUGH the just and liberal action of the Governors of St. Mary's Hospital, who have agreed to devote to school purposes the share of school fees formerly paid to the charity, as stated in the JOURNAL a short time ago, the School Committee have been able not only to appoint a Medical Tutor, but also to establish three Scholarships in Natural Science, each of the annual value of £40, and tenable for three years. The first of these Scholarships will be awarded by open competitive examination in September next. The influence of these newly founded Scholarships will be in the right direction; they will be an inducement to students to endeavour to acquire some knowledge of natural science previous to entering at a medical school, and thus enable them to give more time to clinical work afterwards.

#### ST. THOMAS'S HOSPITAL.

ON Wednesday evening there was a dinner festival to commemorate the opening of the new hospital by the Queen, and to assist in raising the sum of £20,000 for the cost of fittings, furniture, and other items of expenditure connected with the adaptation of the buildings to the purposes for which they have been erected. Sir Francis Hicks, Treasurer, presided. The Chairman, in proposing the toast of the evening, "Prosperity to St. Thomas's Hospital," spoke of the institution in the words of Miss Nightingale as "the noblest building yet erected for the good of our kind". His hearers, he said, when they thought of all that was implied in wishing prosperity to the hospital with its six hundred beds, of the prolonged life and restored health to the many thousands who every year thronged its walls, and of the benefits to mankind at large which must arise from its contributions to medical science, would all rejoice at the conclusion of the great work, and feel that it would have been a timid policy to have delayed its completion. It had been suggested that the governors might have put a smaller limit upon the intended accommodation of the hospital; but every block of buildings not utilised implied that eleven hundred less of our fellow-creatures would have been annually received within the walls, and six or seven

hundred less lives would have been preserved by the medical staff. The subscriptions amounted to £11,000. With a very slight effort, it will, we apprehend, be easy to obtain the further sum needed for the important end in view.

#### JOHN HUNTER.

In the *Times*, of October 1866, appeared an interesting account of Old Kensington Church and the historical personages connected with it and the parish; conspicuous amongst these is John Hunter, who for nearly thirty years laboured diligently on his own freehold at Kensington; here, in fact, he worked out those great principles which have immortalised him. The house, grounds, dens, etc., at Earl's Court, remain but little changed since his day, but the lease of the property is well-nigh expired, and in a short time these interesting acres will be built over, and then will be lost all trace of the home of the sagacious founder of scientific surgery. Under these circumstances, it has been proposed to commemorate John Hunter's long and useful residence in Kensington by placing a window in the magnificent new Church, now nearly completed, by Gilbert Scott, R.A., and thus associate this great benefactor of the human race with Newton, Addison, and others, whose memory will be there represented. We heartily commend the project to our profession and to the public. Mr. John Merriman, of Kensington Square, acts as honorary secretary to the fund.

#### ENTERTAINMENTS IN HOSPITALS.

AT the Royal Free Hospital, an entertainment was given this week to the patients by the North London Glee Club. We are always glad to chronicle such kindly and pleasant reunions. The chronicler of the establishment has, however, gone a little further than the facts in the ecstatic paragraph circulated, declaring this "to be the first time such a thing has been thought of in a hospital". It has been thought of, and carried out, scores of times in dozens of hospitals—but the more often the better.

#### THE HOSPITAL VISITING SOCIETY.

ARCHBISHOP MANNING preached last week at the Pro-Cathedral, Kensington, to a very large congregation, on behalf of a society consisting of several ladies who visit hospitals in London, and do all they can to add to the comfort of the patients. The Archbishop said that he wished to take that opportunity to thank publicly the managers and the medical officers of the hospitals for the facilities courteously afforded to the visitors. One branch of the society consists of those who, on being informed that patients have been discharged convalescent, visit them at their residences, or place them in a convalescent home.

#### OUR ASYLUM SYSTEMS.

WE publish in another column a reply by an able alienist to our recent article on this subject. "S. W. D. W." is evidently a "physician superintendent", and of the class, therefore, that we desire to see increase. We are satisfied with his admission that "there is much that is true" in the views we have expressed, inasmuch as they are largely opposed to existing arrangements, and are hardly likely to be at once or unanimously adopted. The five names he cites precisely illustrate our views; they are the names of men who have all great experience either in the army or in general or hospital practice. We have, of course, never intimated that drugs are not tried in asylum practice. But what, if any, have thus far been the precise results attained? Is S. W. D. W. able to maintain the statement that the use of bromide of potassium in epilepsy is due to an alienist? We were disposed to attribute it elsewhere. The advocacy of a lay superintendent is a windmill erected by our correspondent for the sake of battering it down. The argument in the article to which he replies was that, apart from the medical element, there is nothing more complicated in the management of a lunatic asylum than of a workhouse or prison. A real physician is the only person fit to be the superintendent of a lunatic asylum—and one who, as a physician, thoroughly subordinates lay duties of administration.

## ABORTION-MONGERS.

CHARLES DE BADDELEY, herbalist, and Sarah de Baddeley, his wife, were indicted on the 14th instant for unlawfully supplying a certain noxious drug; namely, ergot of rye, knowing that it was intended to procure abortion. The prisoners lived at Kennington, and an advertisement was inserted in a certain spiritualist journal inviting people to consult at that house "Madame de Baddeley, the celebrated *clairvoyante*." From what was alleged to be transacted there the police were induced to send a woman named Hansard to consult the prisoners, and to concoct a story which might elicit their mode of procedure. After being put into a state of so-called "*clairvoyance*", the female prisoner advised her what to do in the case of a young woman whom she had mentioned, and gave her a quantity of ergot of rye to procure abortion. In all, £6 was paid to the prisoners. The drug was at once handed over to the police. It was urged on behalf of the prisoners that no offence had been committed; and some strong observations were made as to the conduct of the police in laying the trap by which they had been caught. The jury found the prisoners guilty, and they were each sentenced to twelve months' hard labour.

## MEDICAL EXPERTS IN COURTS OF LAW.

COMMENTING upon the evidence of Messrs. Gay, Carr Jackson, and Haynes Walton in the recent stabbing case at Bayswater, the *Standard* says (and we cannot gainsay it):—

"The least satisfactory feature in the trial was the medical evidence, on which the prisoner was compelled to rely. Her defence consisted in an assertion that the wound had been inflicted in a struggle with the deceased, in the course of which he pulled down her uplifted arm, and thus accidentally drove the knife into his own body. But this theory was too manifestly and palpably absurd to hold water. The blade had passed between the ribs, cutting through coat, waistcoat, and body linen, and piercing the flesh for several inches. The course of the wound was directly 'downwards, forwards, and inwards,'—appearances which were consistent with the proposition that a blow had been struck, but utterly irreconcilable with the theory that it had been accidentally and involuntarily given by the deceased when struggling with his companion. Moreover, as one of the doctors called for the defence admitted, the wound was cleanly cut, as it would be if the recipient were struck suddenly and unawares, while any change of position, such as would inevitably occur during a struggle, would jag the edges of the wound and alter the course of the lethal weapon. Mr. Serjeant Parry, in an eloquent address, which was deservedly commended by the Bench, endeavoured to conquer the difficulties with which he had to contend, and to reconcile the ascertained facts with the theory which his witnesses had set up. But the task was too hard, even for the most ingenious and eloquent of advocates. The necessities of the defence did but furnish another proof of the worthlessness of what is known as the testimony of experts. Mrs. Newington's medical witnesses were open to the remark that they were speaking less with reference to the ascertained circumstances of the case than to frame a theory of their own which might justify a verdict of acquittal. We can understand the embarrassments of their position, but we cannot approve their way of extricating themselves from them. We are willing to accord all due weight to scientific opinion, but we consider it a misfortune, alike for the public and for the savans, when it becomes evident that such opinions may be obtained by any one who is willing to pay the market price for them. In actions for damages this is quite bad enough, but it is infinitely worse when the same means are employed at inquiries consequent upon the deaths of those who have gone to their last account, and which intimately concern the lives and limbs of all whose evil hap it may be to suffer from excesses of ungovernable passion and the outbreaks of lawless violence."

## TECHNICAL PLEAS.

WE view with unmitigated disgust the defence put forward by the St. Pancras guardians in the recent action brought against them by Mr. D. H. Dyte for the breach of contract involved in his removal from the post of medical officer of the Highgate Infirmary—an office which he had filled with credit and ability for six months, and which he was engaged to fill until the Infirmary was transferred to the Central London Sick Asylum District Board. In lieu of assigning any reason for an act of injustice which is stated to have been nothing more than the gratification of party feeling, the guardians set up a defence which can only

excite contempt and disapproval. From a report of the trial which occupies several columns of the *St. Pancras and Holborn Journal* of last week, we find that the guardians, without attempting to meet the merits of the case, avail themselves of the technical pleas—first, that the engagement under which Mr. Dyte had been acting had not received the corporate seal, and therefore was not valid; and secondly, that a statement formally and deliberately made by a committee acting on behalf of the Board was not binding on the Board. The defendants not disputing any of the plaintiff's statements, but resting their defence solely on the technical points, the judge ruled that, there being nothing for the jury, the plaintiff must be nonsuited, but with leave to move the Court to set it aside and enter a verdict for himself, subject to these and other points of law raised. The case, therefore, will be argued before the higher tribunals. We are glad to hear that the legal expenses which Mr. Dyte will incur in carrying his case elsewhere are being met by a subscription; and we trust he will receive such liberal support as will enable him to defeat the counsels of the St. Pancras Board of Guardians.

## ARSENIC IN WALL-PAPERS.

THE following communication comes to us from a writer not belonging to our profession, but whose intelligence and trustworthiness is vouched by an eminent sanitary authority.

In the present condition of the public health, it is universally admitted that sanitary improvements are of vital importance. I beg, therefore, to draw the special attention of the Medical Profession and of the public generally to the very serious amount of atmospheric poisoning which has been going on unnoticed and unchecked for many years, and is on the increase all over the kingdom in the houses of the upper and middle classes, and also of the artisan and working classes, in the form of arsenical wall-papers.

Hitherto it has been generally supposed that only papers *entirely* green, and of a very bright shade of green, were arsenical; but the fact is, as proved by the analysis of eminent chemists, that *every paper which contains any green in the pattern, no matter how little, or of what shade, as a general rule contains arsenic, and is, therefore, injurious to health.* One shade of green is no safer than another, for the very palest greens frequently contain large quantities of arsenite of copper, the brilliant colour of which is toned down to any degree of paleness by the addition of chalk, and sometimes of white lead; the result being that pale green papers often contain just as much arsenic as those of brighter colour. The quantities of arsenic used in green papers appear almost unlimited, varying from the fractional part of a grain up to the frightful amounts of six, nine, fourteen grains and upwards, to the square foot. I have beside me some pale green papers, the analysis of which give those amounts, and the illnesses produced by those papers proved in some cases all but fatal. I have also by me a paper with green leaves on a white ground, containing no less than eight grains to the square foot, which caused most serious illness. Papers of a very similar description are to be seen in the majority of dwelling-houses, from the palace down to the navvy's hut. It is rare to meet with a house where arsenic is not visible on the walls of at least some of the rooms. When obliged to leave home for a time last summer, I rejected upwards of seventy lodging-houses, because in none of them could there be found six rooms where the papers were free from green colouring.

When the atmosphere of dwellings all over the kingdom, in town and country, is thus more or less poisoned with arsenic, the most volatile and the most subtle of all poisons, need we be surprised at the increasing prevalence of various forms of disease? Investigation of this subject is urgently called for. I cannot but regard it as a question of great national importance, affecting masses of our population physically, mentally, and morally, to an extent little conceived at present. There appears good reason for believing that a very large amount of sickness and mortality among all classes is attributable to this cause, and that it may probably account for many of the mysterious diseases of the present day which so continually baffle all medical skill.

Arsenic being exceedingly volatile, its effects by inhalation, both of gaseous emanations from the papers, and of the fine impalpable dust thrown off at all temperatures, are highly dangerous, producing symptoms both chronic and acute, which simulate various forms of disease. I say simulate, because I have seen cases where the symptoms of various diseases were produced by the irritation of the entire mucous membrane, and consequently of the whole system, resulting from the occupation of rooms with arsenical wall-papers; and on the removal of those

papers the symptoms gradually subsided, thus proving that they were the result of irritation, and not of organic disease. But it would seem not improbable that prolonged exposure to the same poisonous influence may in time produce those diseases which are at first only simulated.

Having witnessed the effects of slow-poisoning by arsenical papers in my own family and household during a number of years, and having suffered severely myself from the same cause, I speak from personal experience. During a period of twelve years we were rarely free from illness in some form or other. No fewer than twelve physicians, several of eminence, were consulted in London and elsewhere. They all agreed as to the diseased conditions which existed, but not one succeeded in affording more than a measure of temporary relief. Children and adults of both sexes, including several servants, and numbering altogether fourteen persons, all suffered. The peculiar nature and obstinacy of the symptoms were such that I could not but think sometimes that some hidden cause was at work; which analysis of the papers of rooms occupied during those twelve years has since proved to be indisputably the case. The idea that arsenic papers were the cause of illness was suggested by the perusal of a little book not long since published, entitled *The Green of the Period* (Routledge, 1869), which gives much valuable information on the subject, and was put into my hands by a physician who was attending us. The proof that such was really the case lies in the fact, that on removing all the papers containing green the symptoms were soon greatly relieved. To detail them in full would soon occupy much space, but I will give a brief outline.

First appeared irritation of the mucous membrane, causing diarrhoea and vomiting, with various other symptoms of severe gastric derangement, resulting in permanent indigestion; also incessant severe cold in the head, which in one instance lasted for several years without being touched by any remedy; ulcerated throats, with acute inflammation, resembling diphtheria and quinsy; severe spasmodic cough, spasmodic asthma, bronchitis, and congestion of the lungs; soreness of the mouth, lips, and tongue, which appeared as if scalded in patches; inflammation of the eyes and eyelids (the conjunctivæ being invariably bright red), in one case threatening absolute loss of sight; congestion and torpidity of the liver, with the various symptoms resulting therefrom; and severe bilious and feverish attacks. There was, in short, irritation of every organ. In many cases, if not in all, the action of the heart was weakened, and in some palpitation frequently occurred. There were pains in various parts of the body, especially across the shoulders, down the spine and limbs, also in the joints, which were often stiff and swollen; scaling of the skin, and irritating eruptions, which no remedy ever relieved except Turkish baths. The effects upon the nervous system were most remarkable, producing a thoroughly shattered condition; great irritability, depression, and tendency to tears; with unusual prostration of strength. These latter symptoms were especially marked in the children, and also in servants who had come to the house in ordinarily good health, and who each became affected by degrees as described. The list also includes giddiness, headache, acute earache, and neuralgia; bleeding at the nose; frightful dreams; hysterical attacks; faintness; cramps, rigor, and numbness of the limbs; rigid spasms, and convulsions. The last symptoms developed in the worst cases were loss of memory, and threatenings of paralysis; also spasms with twitching of the body and limbs. At this stage, the cause was found out and the green papers were removed. A most simple but effective Turkish bath was temporarily arranged in the house, and by using it daily the worst symptoms were speedily relieved; the brain-congestion yielding all the more readily to this remedy when the temperature was above 140 deg. F.; the heat being obtained by direct radiation from red hot iron, on the principles laid down in Sir John Fife's *Manual of the Turkish Bath* (Churchill).

All the above symptoms, and many others not mentioned, were gradually relieved by this treatment after the papers were removed. The inveterate nasal catarrh alluded to ceased at once when the papers were taken down, and before using the bath. It had been called hay-fever at one time, and the discovery of the real cause of the affection may, perhaps, throw light upon many similar cases.

Inasmuch as all the symptoms enumerated had previously refused year after year to yield to any mode of treatment, these facts may be considered to prove pretty clearly the serious injury to health and danger to life that result from arsenical wall-papers, and may, perhaps, also serve to indicate one of the best means of eliminating the poison from the system.

There remains, however, a sequel to these cases, proving the existence of arsenic in papers altogether free from green, which fact has not yet been brought before the public.

It is well-known that arsenic produces eruptions, while it is also a valuable means of cure for them in some cases. If records were to be made of the various forms of eruptive disease occurring in patients

who occupy, either by night or by day, rooms containing any green in the paper, valuable information on this point might be obtained.

#### DR. LEWIS A. SAYRE'S TREATMENT OF HIP-JOINT DISEASE.

THE demonstrations and clinical remarks of Dr. Lewis Sayre, of New York, which we recently reported at University College Hospital, have excited a good deal of professional interest. The rapid and excellent results obtained by his light and effective extension-splint, the remarkable series of photographs which he has shown of patients having perfect motion at a newly-formed hip-joint after the subperiosteal excision of the head of the femur and parts of the acetabulum, and the extremely ingenious application of his vertebrated probe for the discovery of dead bone at the bottom of sinuous sinuses, have arrested attention; and he has been afforded the opportunity of demonstrations at St. Bartholomew's, St. Thomas's, the Middlesex, and other hospitals. We furnish in another column a full report of one of these demonstrations, with illustrations which will make the text clear. While losing the warmth and earnestness of manner of the lecturer, and something of the peculiar raciness of diction, this lecture will still be found highly instructive and valuable. This is the second time that an American surgeon visiting this country has brought to the cognisance of the profession here what claims to be a distinct improvement in surgical practice. We are happy to afford the hospitality of our columns to such contributions; and we hope that in the future they may be more frequent. Everything which tends to give to scientific work a truly cosmopolitan character, must be hailed with satisfaction. The excellent work which is being done by our American brethren in medical and surgical practice is too little known in this country. The short visit of Dr. Sayre has, we believe, been gratifying to himself and welcome to the profession here. He has been warmly received by the most eminent surgeons, and his vivid enthusiasm and natural force of character have produced a very favourable impression.

#### THE BANQUET TO MM. RICORD AND DEMARQUAY.

OUR French colleagues have warmly appreciated the honour done to them and to those whom they represented by the brilliant gathering of professional men who so promptly responded to our suggestion that their visit offered a fitting occasion for expressing to our French brethren, who have passed through a period of extraordinary trial, our hearty sympathy and affectionate regard. The medical profession in France rose to the height of its duty, and MM. Ricord and Demarquay offered conspicuous examples of men who preferred self-sacrifice and labour to ease in inglorious retirement. It was this feeling which brought together at a banquet, without any other than the most informal notices, nearly eighty of the busiest hospital physicians and surgeons of London in about forty-eight hours—a feat of which the possibility might otherwise have been doubted. MM. Ricord and Demarquay, who were on the point of leaving London when this idea arose, stayed expressly to receive the honour; and it proved to be equally worthy of them and of those who offered it. Sir William Fergusson expressed very happily the sentiments of the English profession towards our French brethren, and the idea of fraternity which underlay the banquet. M. Ricord replied with the spirit, the grace, and the *esprit*, which through a long life have never failed him, and which have now more ripeness but not less vigour than of yore. M. Demarquay has made many personal friends here by his vigorous, manly, and patriotic attitude, among those to whom before he was only known as a surgeon of scientific repute. Such occasions of ripening mutual acquaintance and cultivating reciprocal friendships amongst men of the same profession, though of different nationalities, are too rare. It is a source, we believe, of just satisfaction that this one has not been lost. Not only did Dr. Paget of Cambridge, President of the General Medical Council, honour our foreign guests by coming expressly to London for the occasion, but all the heads of the leading metropolitan corporations and societies, and many men who rarely encumber themselves with public festivities, attended. Dr. Bulkley, the President of the Academy of Medicine of New York; Dr. Fordyce Barker and Dr. Lewis Sayre of New York; and some other emi-

nent foreign physicians who happen to be in London at this time, were also present. Our foreign guests expressed a wish to frame the *menu* with its list of stewards as a permanent memento, and copies have been since printed on satin and sent to them for the purpose.

#### THE BRITISH INTERNATIONAL AID-SOCIETY.

COLONEL LOYD LINDSAY entertained the whole of the ladies and gentlemen who had been actively employed on behalf of the Society at Greenwich, at the Ship Hotel. MM. Ricord and Demarquay, and Counts Flavigny and Serrurier, were present as a deputation from Paris. The German Societies were represented by Count Andreas Bernstorff. Among the medical men present were Dr. Acland, Dr. Sieveking, Mr. Prescott Hewett, Professor Longmore, Surgeon-Major Wyatt, Mr. Holmes Coote, Dr. Pollock, Mr. MacCormac, Dr. Frank, Dr. T. T. Pratt, Mr. Ernest Hart, Mr. Berkeley Hill, Mr. Arthur Norton, Mr. Beck, Dr. John Murray, Dr. Markheim, Mr. R. W. Parker, Dr. Manley, Mr. Chater, Mr. Sewill, Mr. Attwood, Mr. Dorin, Dr. Junker, etc. Mr. MacCormac replied for the ambulance medical officers, and Dr. Frank for the ladies.

#### BABY-FARMING.

THE Infant Life Protection Committee are now considering their draft report. They have satisfied themselves that a great and criminal destruction of life goes on in great cities; and they have evidence of it on a large scale in London, Edinburgh, Glasgow, and Greenock. It has been shown them that the mortality of illegitimate children in some districts amounts to 60 to 90 per cent.; that in the best managed foundling homes it is 70 to 80 per cent.; while by farming out under inspection—as is now done by the Foundling Hospital, for example—it is brought down to the normal rate of 16 per cent. These facts were established by the evidence of Mr. Ernest Hart, Mr. Curgenven, Mr. Gregory, M.P., Serjeant Relf, and Dr. Cameron. They will, we believe, thereupon recommend—1. The compulsory registration of births and deaths by a medical person; 2. The establishment of permissive registers for all nurses wishing to take children, who will then be subject to inspection; 3. The compulsory registration of all nurses taking more than two alien infants into their house for gain; 4. The registration of lying-in houses.

### SCOTLAND.

THE consideration of Miss Jex Blake's letter has again been postponed by the Senatus of the University of Edinburgh, counsel not having been yet consulted.

MISS JEX BLAKE has received £200 from a lady to form the nucleus of a fund towards the establishment in Edinburgh of a women's hospital for the clinical instruction of female medical students: the staff to be composed also of ladies.

#### THE LADY STUDENTS AND SURGEONS' HALL.

THE Lecturers at Surgeons' Hall have by a majority rescinded the permission given last year to admit ladies to their classes, and they have now determined to prohibit the attendance of lady medical students either separately or in mixed classes. It was, however, resolved that instruction by Dr. Keiller to nurses in midwifery, or by the rest of the lecturers to women in other subjects, would be permitted provided that the women were not "registered students of medicine."

#### THE SANITARY CONDITION OF GLASGOW.

THERE has been for some time a steady decrease in the cases of fever and small-pox in the city, only forty-three of the latter being in hospital at the beginning of the present week. There turns up in Glasgow a periodical outcry from some members of the Police Board against the ever-increasing expenditure of the Sanitary Department. Some years ago, the Fever Hospital at Parliamentary Road was in considerable risk of being abolished; and now it is the recently arranged staff of sanitary inspectors which is the subject of attack. The history of all the epi-

demics since the magistrates have set themselves to encounter this class of diseases seems to us to afford the strongest argument for such measures, and the greatest encouragement to those who advocate them. There was first the cholera epidemic, against which Dr. Gairdner organised such a thorough army of sanitary visitors, and the City erected several hospitals. This epidemic touched Glasgow; there were several cases in various parts of the city, but these were at once conveyed to hospital and the localities disinfected, and the disease went no further. Then we have recently passed through two epidemics—the one of relapsing fever and the other of small-pox, and both have been quite limited in extent, as compared with former epidemics of the same disease here, and especially with simultaneous epidemics elsewhere. There seems to us to be the greatest encouragement, therefore, to go on in this work, and we have no doubt that a sensible difference in the death-rate will be the not distant result.

### IRELAND.

#### SMALL-POX IN IRELAND.

IN an official communication dated July 13th, the Commissioners for administering the laws for relief of the Poor in Ireland state that, since their last circular upon small-pox in Ireland, dated February 7th, 1871, they have had reports from medical officers of 480 cases, distributed through fifty-three unions. Among these, Drogheda shows 127 cases; Belfast, 68; Wexford, 57; North Dublin, 23; and South Dublin, 24. Many cases from centres of contagion, like Belfast, have doubtless escaped being reported. It is not often that the source of contagion, when it is within the country, can be ascertained, on account of the ordinary frequent intercourse between any centre of contagion and the places in its vicinity; but the centres to which the contagion, arising internally, has in a few cases been traced, have been Belfast, Drogheda, Dublin, and Wexford, in the two former of which the disease had assumed the nearest approach to an epidemic. The cases, however, in which contagion has been imported from abroad are more easily ascertainable, and during the five months which have elapsed since the last circular, thirty-five cases have been reported as imported into various parts of Ireland from Liverpool; ten cases from Glasgow; five cases from Wales; and eight cases from other parts of Great Britain. Thus the number of cases known to have been imported from Great Britain into Ireland during the five months was fifty-eight; which added to thirty-four like cases specified in previous circulars make a total of ninety-two cases imported during the year 1870, and that part which is passed in 1871. The promptitude with which the Guardians and their officers have met these imported cases, by efficient treatment, isolation, and disinfecting processes of every description, reflects much credit on the several unions which have been invaded by small-pox, and accounts, at the same time, for the very few instances in which the disease has spread after its introduction. Of cases which have terminated fatally during the five months very few have been reported in the correspondence, and it is not possible to say what the small-pox mortality during the period in question may have been until the Registrar-General's returns have been published. The last quarterly return published was that for the quarter ended December 31st, 1870, and at that time the present invasion of small-pox had scarcely commenced. The weekly tables, however, for the Dublin registration district (population 314,000) exhibit eleven deaths, as registered in that district, from the 7th February last, to the present date. It will probably be found ultimately, from the Registrar-General's returns, that the number of deaths compared even with the imperfect number of cases reported to the Commissioners exhibits a very small rate of mortality, inasmuch as a large proportion of the cases so reported have been described as of a very mild type in consequence of previous vaccination. The principal inferences to be drawn from the figures above presented are the following. 1. The ordinary intercourse prevailing between Great Britain and Ireland has been the cause of introducing small-pox

once more into the latter, the earlier cases having been almost all traceable to importation. 2. Considering the number of different localities in Ireland into which small-pox has been so imported, it is surprising that there are so few in which it has taken such hold as to establish a new centre of infection, such having apparently been the case only in Belfast, Dublin, Drogheda, and Wexford. 3. Those incidents are due in all probability to the comparatively good state of vaccination in the country, combined with other favourable sanitary conditions, the latter being partly due to the absence of any decided epidemic influences, and partly to the progressive operation of the sanitary laws. The Commissioners think that the Guardians will no doubt concur with them in believing that the greatest public benefit has been derived from the law of compulsory vaccination, as administered in Ireland, and from such exertions as have hitherto been made in carrying into effect the Sanitary Act, and will be disposed, under existing circumstances, to continue their exertions for the preservation of the public health.

## A COMPLIMENT TO THE PROFESSION IN FRANCE.

DINNER TO DRS. RICORD AND DEMARQUAY, CHIEFS OF THE AMBULANCES OF THE PRESS OF PARIS.

A COMPLIMENTARY banquet was given to MM. Ricord and Demarquay, with Count Serrurier and Dr. Markheim, Secretary of the delegation from Paris, on Monday evening at Willis's Rooms. Sir William Ferguson, Bart., F.R.S., occupied the Chair. There were also present, Sir A. Armstrong, K.C.B., Director-General of the Medical Department of the Navy; Dr. Paget, President of the General Medical Council; Dr. Burrows, F.R.S., President of the Royal College of Physicians; Mr. Busk, F.R.S., President of the Royal College of Surgeons; Mr. Curling, F.R.S., President of the Royal Medical and Chirurgical Society; Mr. Hilton, F.R.S., President of the Pathological Society; Dr. Gull, D.C.L., F.R.S., President of the Clinical Society; Dr. Braxton Hicks, F.R.S., President of the Obstetrical Society; Dr. A. Clark, President of the Medical Society of London; Capt. Brackenbury; Dr. W. Russell; Dr. R. Barnes; Mr. T. Bryant; Dr. Henry Bennett; Mr. Bowman, F.R.S.; Surgeon-Major Bostock, C.B.; Mr. Brodhurst; Mr. Callender, F.R.S.; Mr. Critchett; Mr. Couper; Mr. Durham; Dr. D'Ormillas; Mr. de Méric; Dr. Gueneau de Mussy; Mr. Erichsen; Staff-Surgeon Fitz Gerald; Mr. Gascöyen; Mr. Hancock; Mr. Luther Holden; Mr. Prescott Hewett; Mr. Ernest Hart; Mr. Berkeley Hill; Dr. Gordon, C.B.; Dr. John Ogle; Mr. Sydney Jones; Mr. Campbell De Morgan, F.R.S.; Mr. Francis Mason; Mr. Maunders; Mr. W. Mac Cormac; Mr. A. Norton; Mr. Paget, F.R.S.; Mr. Partridge, F.R.S.; Mr. John Gay; Dr. Pavy, F.R.S.; Dr. T. T. Pratt; Dr. Priestley; Mr. Quain, F.R.S.; Dr. Owen Rees, F.R.S.; Mr. Savory, F.R.S.; Sir H. Thompson; Dr. Vintras; Mr. Erasmus Wilson, F.R.S.; Dr. Balkeley (New York); Mr. John Wood, F.R.S.; Dr. Wiltshire; Mr. Startin; Mr. Bell; Mr. Holmes Coote; Dr. de Vignola; Dr. Tilt; Dr. Lewis Sayre (New York); Dr. Le Grand; Dr. Fordyce Barker (New York); Dr. Percy (New York); Mr. Acton; Dr. Maclaren; Mr. Adams; Dr. Tanner (Cork); Mr. White Cooper; Mr. A. Goldsmid; Mr. T. M. Stone; Hon. L. Wingfield, etc.

The CHAIRMAN gave "the Queen."

Dr. BURROWS proposed "the Army and Navy Medical Services"; to which Sir A. Armstrong and Deputy Inspector-General Dr. Gordon, C.B., British Commissioner to the French hospitals, replied.

The CHAIRMAN said that time was specially important to most men in the room, and it had been arranged by those who had conducted the ceremonies of the day that some of the toasts incidental to large social gatherings in this country should be omitted; and he now rose to proceed with the business which was uppermost in the minds of all present. They had with them as guests two distinguished members of the medical profession belonging to a neighbouring country, and it was to do honour to them that they were now assembled. Doctors Ricord and Demarquay were as well known to the profession in England as by their brethren at home; their fame had extended over the world, and each had achieved for himself great reputation. But it was not entirely on this account that the present greeting had been offered. Hundreds of men of eminence in the medical profession came to these shores from all parts of the world, and they were kindly received in our hospitals and on other occasions, but it was not always deemed needful to entertain them at public festivals. He believed that those gentlemen usually left our shores well contented with such attentions and hospitalities as had fallen to their lots. But there was something peculiar in the visit of the guests of this evening. They had come to England selected by their own countrymen to perform an unprecedented act of courtesy from our immediate neighbours on the continent—from the French nation;

bearing a message of thanks to the people of England for warm-hearted kindness and sympathy, as well as material assistance, rendered at a time when France was suffering severely under the calamities of war. They had come to offer gratitude and friendship for valuable assistance offered in the time of their greatest need, and to express to us their earnest hope and desire that the friendship which had so long obtained between the two countries might never be broken. These gentlemen had been specially engaged in administering much of those comforts that the people of England had dealt out with such unsparring liberality. They had been at the head of the Ambulance Corps of the Press, which had rendered such invaluable service to the sick and wounded during the calamities of the siege of Paris. It was on this account chiefly that these gentlemen assembled were desirous of offering the present homage, for all felt that Drs. Ricord and Demarquay, with those of the profession who had ably assisted them, had thus put themselves at the head of those movements which the medical profession provided for the public weal wherever danger from the scourges of war threatened. This was a feature connected with the profession which all cherished as its glorious privilege. Despite of disease and danger from bullets, they were ever to be found in the front on such occasions. There had been reason to boast of it since the earliest records of the profession. Nearly three thousand years ago the Greek army, as it lay before Troy, were encouraged in their works by the circumstance that two eminent men were with them—Podalirius and Machaon. It was in those days that our profession had acquired the character of Godlike, because it could afford assistance under circumstances when no other could. In other sieges similar traditions had been referred to, and it was one worth special notice on this occasion that a predecessor of those present guests, a great surgeon of France who flourished three hundred years ago, and had been body-surgeon to several sovereigns of France, had on one occasion been the means of raising a siege of Metz, the very city about which so much had recently been said and done. Paré was smuggled within the walls; and when this was known, the garrison seemed as it were to be doubled in numbers, each man felt himself so much inspirited with the idea that the great surgeon was among them. This revived confidence speedily led to the raising of the siege.

It was for the honour that the guests had recently reflected on our profession, that we desired specially to testify to them our admiration for their conduct and our sympathy for their sufferings during the period of trial and danger. Each of them had already done such good to their fellow-creatures, that they might well have stood aside and let younger men take the posts of danger, but they preferred duty to all other considerations, and all hail to them for their devotion!

These guests in some degree were representatives of that great school of medicine and surgery for which Paris had long been famous, and it was the wish of all Englishmen present to assure these gentlemen of their continued high consideration for that famous school. We must still look forward to aid from it in furthering the progress of the profession at large. He thought it would be appropriate on this occasion to refer to two remarkable improvements of modern times which had emanated from that school. In former days in this country the eminent physician prided himself in carrying a sort of badge of his status, a tall stout, gold-headed cane. They all knew that such a rod had disappeared. It would be a curious sight for them to see Dr. Burrows (President of the Royal College of Physicians) walking down Regent Street with such an emblem in his hand; but he had no doubt that, if the doctor were met under ordinary circumstances, a small bit of wood might be found in his pocket or the crown of his hat—a mysterious looking thing smaller than a field-marshal's baton—he used that word as their friends had lately been military in some respects, yet with a power and quality little less significant than that famous rod. This was the stethoscope, which in its own way did marvels. It had added a new sense, as it were, to the physician; it has added a new eye to his mind, and has given the power to see into the very centre of the body.

The other instance he would take from the side of surgery. Men in England prided themselves upon the famous Cheselden, who had done so much for lithotomy. He was so famous in his time, that surgeons came from France to take lessons from him. But in modern days, the horrors and dangers of that terrible operation had been largely set aside by lithotripsy, and it was to the French school that we owed the commencement of that beneficial proceeding which had conferred health and happiness on many—from the sovereign on the throne to the lowly peasant or humble artisan. Of this the surgeons of France might well be proud.

Messieurs Ricord and Demarquay—these gentlemen have deputed me to address you as I might. I wish, for their sake and yours, that the task had fallen to some one more able to fulfil it. In the name of every one present, I have to offer you good and kind wishes. I request that you will convey to your brethren in Paris our continued profound respect

and esteem; and we cordially hope that this visit of yours may be the means of drawing together more firmly those bonds of friendship which we desire to see permanently uniting these two great nations. [Applause.]

M. RICORD (who was received with loud applause) said: It is with most pleasurable emotions that I rise to thank you all, and your eminent chairman, for the kind manner in which he has proposed, and you have received, our health. My pleasure is great and my emotion is heightened, when I look round this banquet-room and recognise so many faces of friends—some of them dear ones; many, I am proud to say, former pupils of mine. In fact, it almost seems to me that I am once again under the shade of the old lime-trees in the "Hôpital du Midi", encouraged (as usual in my lectures) by your presence and approbation. It is no small satisfaction to me, after so many years, to find myself again amongst you, and to feel myself supported by such a distinguished gathering of English *confères* met together with such kind intentions, such good feelings towards the profession in France—feelings which, I am sure, are most heartily reciprocated. Since the happy time to which I have alluded, we in France have had to pass through much affliction, sorrow, and suffering. At times, so great was the danger, and so depressed were we, that I often gave up all thought or hope of seeing my friends again; and little did I dream of meeting you here and enjoying the cordial greeting which you extend to me and to our friend Dr. Demarquay.

The siege of Paris has been more or less to us, to our society of the French ambulances, to the medical profession both in Paris and England—in fact, both far and wide—the siege of Paris has been, I say, the source of anxiety and some very arduous work. Those of us who were more immediately, more actively, engaged in the work, had to fulfil our professional duties under various and most trying conditions of danger and difficulty. In the ambulances of the French press-fund, we had but very scant notice and a very short time to call together and organise a numerous staff of workers and assistants of all sorts. One thing was most satisfactory, and that was the alacrity with which, at my call, there came together one hundred and fifty doctors, surgeons, and dressers, belonging to our civil hospitals—amongst them some of the most eminent hospital surgeons, some members of the Société de Chirurgie or of the Académie de Médecine; others professors of the Faculté. We also had the good fortune to be joined and most ably seconded by our distinguished *confères* Drs. Gordon and Wyatt; and later on, during the civil war, by my young friend Dr. Markheim, who most courageously came forward in the time of need, and generously gave us the benefit of his talent and energy. Besides this numerous medical staff we had with us nearly fifty *pharmaciens*, many of them most eminent men, who also responded to the call of our Society. With such a staff at our disposal, we were able to establish fourteen sedentary ambulances (if I may so term our various hospitals scattered all over Paris), and five *real* ambulances (for they were *perambulating*, or *ambulances volantes*, as we called them). Most ably seconded by a very efficient commissariat and transport service of our own, we made it our duty to attend on all the battle-fields round Paris, dressing the wounds of the sufferers on the spot, or bringing them away with all speed to our fixed ambulances in town. Our labours were of necessity confined to the capital, whilst the operations of the French branch of the International Red Cross Society were happily extended over the provinces at large. My worthy friend and brother President, Count Flavigny, has, I am sorry to say, been obliged to return to Paris yesterday; but I have no doubt that Count Serrurier, Vice-President of that Society, could give some most interesting facts as to the work of the French Red Cross Society.

The *Ambulances de la Presse Française* were the offspring of a subscription set on foot by the French Press Committee (presided over by M. Edmond Tarbé), and most liberally responded to by the public. Thanks to their generosity, and to the efficient management of our very able general secretary, M. de la Grangerie (who narrowly escaped the unhappy fate of the poor Archbishop, whose prison he had shared), we were enabled to care for the 25,000 sick, as well as wounded, who passed through our hands. But it would be the blackest ingratitude in me as a Frenchman, were I to pass over in silence the great sympathy and material help so kindly and generously extended to us by our English *confères*, several of whom devoted their time, their talents, and their energy, to a labour of love and brotherly sympathy, thus setting an example which has been most nobly followed by the generous British public. It might be considered invidious to quote single instances among so many examples; but I seize this opportunity of expressing my satisfaction at having made the acquaintance of Drs. Frank and MacCormac of the Anglo-American Ambulance, to which Dr. Markheim was attached; of Mr. Ernest Hart and Mr. Berkeley Hill, who served greatly our French ambulances at Sedan and Remilly; also of Dr. Pratt, who comes from that noble country America, the home of my

earlier years. May you in happy old England never have to learn by experience the bitter lessons that have been taught us within the last twelvemonth; nevertheless, should fate order otherwise, we shall know what we ought to do, thanks to your noble example. Need I say that we should strain every nerve to imitate you? This is all very well and very praiseworthy; but France and humanity at large are under far deeper obligations to England, which has given us such men as Sydenham, whose name is always most reverently pronounced in France; Charles Bell, to whose laws, one might say, our movements, our very feelings, must obey; the other Bell, whom I call "mon Benjamin"; Hunter—let me say my Hunter, for if he does not belong to me I belong to him; Lawrence; Sir Astley Cooper; Sir B. Brodie, who was kind enough to receive me for the sake of my father, when to his surprise I was obliged to inform him that I was my own father! my old friend Guthrie; and many others whose names will readily occur to you, and who have been so brilliantly succeeded in the present time by what we call in France *une brillante pleiade*, whose names crowd into my memory. The list is long; many are here present; some are away; but they are all inscribed in my heart.

Unhappily, our troubles were not ended with the siege. We had to drain the cup to the dregs. A civil war broke out, unparalleled in history, both ancient and modern—unequalled either for the ferocity of the wretched leaders of a misguided and half-starved populace, or for the anguish it caused all honest people. What were the vicissitudes of the *Ambulances de la Presse*—what happened, in fact, during the gloomy reign of Communal terror, will be more forcibly, more vividly, described by one of the principal actors, my courageous friend, my *alter ego*, Dr. Demarquay, who took the command on my being called away to Versailles.

Now let me again thank you in my own name, in the name of the French profession whom you wish to honour in our persons, and to whom I will, on my return, relate your kindness, and show the honourable roll of your names. Let this banquet be the bond of sympathy and friendship for ever, not only between English and French doctors, but between the English and French nations. [Applause.]

M. DEMARQUAY (who was loudly cheered) said: My first duty, gentlemen, is to thank you for having associated my name with that of M. Ricord. I cannot, however, form such a mistaken opinion of my own merits, as not to perceive that I owe this honour to your great kindness, and especially to your friendship for our master, for whose sake you have organised this splendid assemblage. In associating me with that great and illustrious man M. Ricord, you have desired to render homage to the surgical body of Paris, to the Society of Surgery, and to the Academy of Medicine, to which I have the honour to belong. It is by placing myself in this point of view, that I feel justified in being here; and I am profoundly grateful for your kindness and for the marks of sympathy with which you are kind enough to honour me. Permit me, also, from the elevated position in which you have placed me, to express to you our lively acknowledgments of the sympathy which you have manifested towards unhappy and conquered France, saddened by a civil war without an equal in modern times, but now raising herself with courage from her overthrow. Any one who would fully understand our friendship for you, and our gratitude, must imagine himself placed in a large besieged town into which nothing could penetrate, and where the primary necessities of life were beginning to fail. Well! gentlemen, it was in such a town that the echoes which reached us from without informed us that many of you had left your families and your affairs, and, led on by the noble impulses of your hearts, had come to take care of our wounded. This mark of sympathy was deeply felt by the whole of the medical profession in France; which, in the painful circumstances, showed as much courage as devotedness from those in the first rank, at the head of whom I will place MM. Ricord and Nélaton, to the humblest country doctor. These painful events have established between the English and French surgeons bonds of friendship which time will only strengthen. During our time of trouble, we contracted yet another debt of gratitude towards England, by receiving from your generous nation the gifts which Colonel Lindsay courageously brought us under the protection of the Geneva flag. Honour, then, to the English people! honour to the medical profession of that noble country, which has shown us so much sympathy, and whose generosity has loaded us with gifts which have enabled us to afford comfort to the victims of the war, as well as to the cultivators of our land, whose harvests were mercilessly destroyed.

Permit me now to give you my personal thanks for your kind expressions regarding the painful time which we passed under the Commune. Two motives determined me to remain at my post during those sad days when M. Ricord, in order that he might not be included among the hostages, was obliged to leave Paris. I desired to protect the ambu-

lances of the Press against all encroachment, and to prevent the young medical men who had courageously aided us from being forcibly incorporated in the army of the Commune. And I further desired to affirm the principle that every wounded man, whoever he may be, when he is protected by the noble Geneva flag—the symbol of Christian charity—ought to lose all nationality and all political colour, and become merely a wounded man, claiming, as such, care and protection. This task was also imposed on himself by Dr. Chenu; and it was a difficult one. We had much to bear in maintaining our rights, and in making our services appreciated.

At the commencement of the rule of the Commune, M. de la Gran-gerie, our General Secretary, was arrested, and detained as a hostage with the Archbishop of Paris and with M. Bonjean, that noble victim of the French magistracy. To obtain his liberty, I was obliged to apply in succession to M. Raoul Rigault, of celebrated memory; to Deles-cluze; to Protot, Minister of Justice; and to Cluseret. It was not till after twelve days of applications, entreaties, prayers, and threats, that we were able to remove our good and brave colleague from the prison of La Roquette, where he occupied the cell of the too celebrated Troppman. Dr. Chenu, the excellent representative of surgery in the International Society for the Aid of the Wounded, had the honour to undergo imprisonment as a reward for having worthily performed his duty. Well! gentlemen, in these days of trouble, Parisian surgery still maintained the position in which duty placed it; and I must further add that your young and courageous countryman Markheim never ceased during the time of the Commune to bestow his care on the wounded, and to act as the medium of communication between M. Ricord and myself.

The grand proof of esteem and friendship which you have given permits me to conclude my speech with proposing as a toast "The Union of English and French Surgery", which up to this day have done most in Europe, by the extent and the importance of their labours, for the good of humanity.

Mr. PAGET proposed "The International Aid-Societies of England and France", and spoke of the great works done by the French societies over the whole field of war in France, and especially within the walls of Paris during both the sieges. He expressed the earnest hope that the proof of national friendship and mutual benevolence which was afforded by the works of all the aid-societies of Europe would lead in time to a thorough hatred of war and a strong resolve against it.

Count SERRURIER and Captain BRACKENBURY replied.

Dr. GULL proposed "The Press and its Good Works". Drs. Ricord and Demarquay were the representatives of a noble work of the French Press—its ambulances—founded and sustained by the exertions of the Press. The Crimean Fund of the *Times*, the funds for the relief of the sufferers around Sedan, Metz, and Paris, were examples of the good works of the English Press. Than Dr. Russell no more apt representative of their works could be found. The present gathering, and the opportunity which it afforded of drawing together in closer bonds of friendship two great nations and two great professions, were due to the initiative of Mr. Ernest Hart, a leading mind in the medical Press, aided by the exertions of Sir Henry Thompson. He coupled with this toast the names of Dr. William Russell and the Hon. Lewis Wingfield.

Dr. RUSSELL said that the Press usually preserved a decorous silence as to its good works. It had sometimes, he feared, to answer for exciting passions, and producing unpleasant irritation. Such works as those alluded to redeemed its character. A long experience of wars gave him a continually growing horror of its cruelties. He trusted that the influence of the Press might be used to avert the causes of war, to mitigate the sufferings incidental to it, and to support those who devoted themselves to such noble work as that which he had seen under the Red Cross.

**THE MUSWELL HILL ESTATE.**—The new project for supplying the North of London with gardens as extensive and as beautiful as those of Sydenham will attract the interest and favour of all Londoners, who know how much thickly crowded populations stand in need of multiplied facilities for healthful outdoor recreation.

**ROYAL COLLEGE OF SURGEONS: PUNISHMENT.**—At the last meeting of the Council of the Royal College of Surgeons, a letter was read from Messrs. Wilde, the solicitors, enclosing a copy of the conviction and of the sentence to six months' imprisonment of Frederick Henry Morris, a member of the College, who was tried at Devoizes on March 27th last for an indecent assault; and it was resolved that, in pursuance of the bye-law relating to the misconduct of Fellows and Members, he be removed from being a member of the College. His name has also been removed, by order of the Medical Council, from the *Medical Register*.

## ASSOCIATION INTELLIGENCE.

### BRITISH MEDICAL ASSOCIATION: ANNUAL MEETING.

THE Thirty-ninth Annual Meeting of the British Medical Association will be held in Plymouth, on Tuesday, Wednesday, Thursday, and Friday, the 8th, 9th, 10th, and 11th of August next.

*President*—E. CHARLTON, M.D., D.C.L., Physician to the New-castle-upon-Tyne Infirmary.

*President-elect*—JOHN WHIPPLE, Esq., F.R.C.S., Consulting Surgeon to the South Devon and East Cornwall Hospital.

An *Address in Medicine* will be delivered by GEORGE JOHNSON, M.D., F.R.C.P., Professor of Medicine in King's College, London.

An *Address in Surgery* will be delivered by JOSEPH LISTER, Esq., F.R.S., Professor of Clinical Surgery in the University of Edinburgh.

The business of the meeting will be conducted under four Sections.

**SECTION A. MEDICINE.**—*President*, Dr. Barham, Truro. *Vice-Presidents*—Dr. Quain, F.R.S., London; Inspector-General Smart, M.D., C.B., R.N., Penge, Surrey. *Secretaries*—Dr. Clay, Windsor Villas, Plymouth; Dr. Wade, Temple Row, Birmingham.

**SECTION B. SURGERY.**—*President*—Joseph May, Esq., Stoke, Devonport. *Vice-Presidents*—P. C. De la Garde, Esq., Exeter; Deputy-Inspector-General Longmore, C.B., Netley. *Secretaries*—W. P. Swain, Esq., Ker Street, Devonport; C. Steele, Esq., Meridian Place, Clifton, Bristol.

**SECTION C. MIDWIFERY.**—*President*—Dr. Beatty, Dublin. *Vice-Presidents*—Dr. Swayne, Clifton, Bristol; Dr. Alfred Meadows, London. *Secretaries*—Dr. John Rolston, Stoke, Devonport; Dr. Phillips, 26, Finsbury Square, London, E.C.

**SECTION D. PUBLIC MEDICINE.**—*President*—Dr. A. P. Stewart, London. *Vice-Presidents*—P. W. Swain, Esq., Stoke, Devonport; Dr. Beddoe, Clifton, Bristol. *Secretaries*—Dr. Row, Ker Street, Devonport; David Davies, Esq., 2, Queen Square, Bristol.

TUESDAY, August 8th.

The meetings this day will be held at the Royal Hotel, PLYMOUTH.

1 P.M.—MEETING OF COMMITTEE OF COUNCIL.

3 P.M.—MEETING OF GENERAL COUNCIL.

8 P.M.—FIRST GENERAL MEETING. *Business*: a. Reception of Congratulatory Address from Plymouth Corporation; b. President's Address; c. Vote of thanks to the President; d. Report of Council, and Discussion thereon; e. Election of General Secretary; f. Election of Auditors; g. Report of Medical Benevolent Fund; h. Presentation of Hastings Medal.

WEDNESDAY, August 9th.

8.30 A.M.—PUBLIC BREAKFAST—Royal Hotel, DEVONPORT.

9.30 A.M.—MEETING OF NEW COUNCIL—Royal Hotel, DEVONPORT.

11 A.M.—SECOND GENERAL MEETING—Town Hall, DEVONPORT.

*Business*: a. Reception of Congratulatory Address from Devonport Corporation; b. To appoint place of meeting for 1872, and President-elect; c. Address in Medicine by Dr. GEORGE JOHNSON.

1 P.M.—Adjourn.

2 P.M.—MEETINGS OF SECTIONS—Royal Hotel, PLYMOUTH.

9 P.M.—PRESIDENT'S SOIRÉE—Assembly Rooms, Royal Hotel, PLYMOUTH.

THURSDAY, August 10th.

10 A.M.—THIRD GENERAL MEETING. *Business*: Reports of Committees—Royal Hotel, PLYMOUTH.

11 A.M.—ADDRESS IN SURGERY, by Professor LISTER, F.R.S.—Royal Hotel, PLYMOUTH.

2 P.M.—MEETINGS OF SECTIONS—Royal Hotel, PLYMOUTH.

6.30 P.M.—PUBLIC DINNER—St. George's Hall, STONEHOUSE.

FRIDAY, August 11th.

10 A.M.—MEETINGS OF SECTIONS—Royal Hotel, PLYMOUTH.

2 P.M.—CONCLUDING GENERAL MEETING—Royal Hotel, PLYMOUTH.

A RECEPTION ROOM will be opened at the Royal Eye Infirmary, close by the Plymouth Railway Station. Members and others who require information with respect to the meeting are requested to make application in this room.

Members are requested to proceed to the Reception-Room immediately on their arrival, to enter their names and addresses, and to obtain the tickets necessary to secure admission to all the proceedings.

**HOTELS.**—The principal hotels are, at PLYMOUTH, the Royal Hotel, the Duke of Cornwall, the Globe, the Albion, Chubb's Hotel, Farley's Hotel, Harvey's Hotel; at DEVONPORT, the Royal Hotel, Thomas's Hotel, and the Crown Hotel.

\* \* \* **GENTLEMEN INTENDING TO VISIT PLYMOUTH** during the meeting are requested to send their names to Dr. Littleton, the Local Secretary, 1, Lansdowne Place, Plymouth.

**NOTICES OF MOTION.**—The following notices have been given.

The **PRESIDENT OF THE COUNCIL**: Rule 4. To insert "President-elect", and to omit "Secretary".—Rule 6. To expunge this rule, and to substitute the following: "Each retiring President of the Association and President of Council shall be appointed a Vice-President for life by a vote of the members at the Annual Meeting."—Rule 7. To add "the Vice-Presidents" after President-elect; to insert the word "and" between President of the Council and Treasurer, and to erase "and the Secretary".—Rule 8. In this and every rule where "District" is prefixed to Branch, to erase the word "District", and to erase the words "the Secretary of the Association".—Rule 9. To omit the words between "The President of the Council" and "shall be elected".—Rule 10. To omit the words between "The Treasurer" and "shall be elected".—Rule 11. To erase the words after "There shall be one paid Secretary" in first section, and to substitute "who shall reside in London, and devote his whole time to the business management of the Association and of the JOURNAL office". To erase the words "otherwise" in seventh line and "an annual or special" in eighth line, and to insert "each Annual Meeting".—Rule 13. To erase the words "Secretary shall call", and to substitute "President of Council shall direct to be called".—Rule 14. Between "shall" and "be recommended", to insert "express his desire in writing, and shall be".—Rule 15. To add "Members may be admitted on and after July 1st in each year, and the subscription for such part of a year shall be half a guinea". To erase the words after "such member" in eighth line, and to substitute "as long as his subscriptions remain unpaid, provided due notice shall have been given of such withholding".—Rule 16. To erase the words after "from his" in fourth line, and to substitute "liabilities to the Association".—Rule 24. In tenth line, to insert "a copy of the laws" between "Association" and "and".

**Dr. STEELE (Liverpool)**: Election of Committee of Council. Every associate, who is a member of the Council, and desirous of a seat on the Committee of Council, shall send to the General Secretary, not later than months prior to the Annual Meeting of the Association, a declaration signed by himself, and in the following terms: "I, A. B., of C., member of the British Medical Association, hereby declare that I am a candidate for a seat on the Committee of Council of the said Association. (Signed) ———." Together with a nomination-paper signed by six members of the Association, in the following terms: "We, the undersigned, members of the British Medical Association, certify that A. B., of C., is a fit and proper person to be a member of the Committee of Council of the said Association." The names of the eligible candidates, with the names of the six associates by whom they shall have been respectively nominated, shall be published in the **BRITISH MEDICAL JOURNAL** not later than months prior to the Annual Meeting of the Association.

**Mr. NICHOLSON (Hull)**: To alter Law 16, line 2. For "three", insert "two".

**Dr. WADE (Birmingham)**: In Law 8, Paragraph No. 3, of the duties of Council, to alter "ten" into "twenty-five"; and to omit the words "and one Secretary from each Branch".

**INVITATION TO TORQUAY.**—The members of the medical profession at Torquay request the pleasure of the company at luncheon, on Saturday, August 12th, at 3 o'clock, of any member of the British Medical Association residing beyond fifty miles from the place. Their object in this limitation as to distance is that of furnishing an opportunity to strangers unfamiliar with Devonshire to become acquainted with Torquay and its immediate neighbourhood. Any member who may wish to favour them with his presence, will oblige by notifying the same at his early convenience—and not later than on the Wednesday of the Plymouth meeting—to the Honorary Secretary, Dr. Powell, Infirmary, Torquay.

**SPECIAL RAILWAY ARRANGEMENTS.**—First and second class ordinary and express return tickets issued at any Station on the Bristol and Exeter Railway, or on the South Devon, Cornwall, or West Cornwall Railways, on August 7th and following days, will be available for the return journey to and from Plymouth any day up to and including Monday, Aug. 21st. First and second class return tickets, at single fare for the double journey, available as above, may be issued from any Station on these lines to Plymouth, or from Plymouth to any South Devon, Cornwall, or West Cornwall station, on August 7th and following days to

August 21st inclusive, to the members of the *British Medical Association* producing a certificate or the Association card of membership. Unless such documents be produced, return tickets at ordinary or express fares must be issued. When tickets at single fare for the double journey are issued, the booking clerks must write "return" upon them, and place their initials below the word "return". Ordinary tickets endorsed "return" will be available by express trains without payment of the difference of fare. The South Devon, Cornwall, and West Cornwall Railways have also promised to convey any instruments, medical and surgical appliances, etc., for the Annual Museum, at half the usual fares, at the owner's risk.

**EXCURSIONS, ETC.**—The Local Committee appointed by "The Three Towns", Plymouth, Devonport, and Stonehouse, to prepare for the annual meeting of the British Medical Association in 1871, have much pleasure in acquainting the members that they have succeeded in obtaining the cordial cooperation and assistance of the civil and military authorities; so that every facility will be furnished them for inspecting this naval and military arsenal; Her Majesty's ships of war in the Hamoaze and Plymouth Sound; Her Majesty's dockyards at Devonport and Keyham; the Royal William Victualling Yard and the naval and military hospitals in Stonehouse; the Breakwater and its lighthouse; the Eddystone Lighthouse; the Plymouth Citadel, the Hoe, and the forts recently erected within a radius of five miles.

By the kind permission of His Grace the Duke of Bedford, the Right Honourables the Earl of Mount Edgumbe, the Earl of St. Germans, and the Earl of Morley, and other gentlemen, opportunities will be offered to the members of surveying the grounds and the extensive views commanded in the parks attached to their mansions on the banks of the Tamar and Plym; whereby they will be enabled to pass in review the objects before-named, as well as the magazines at Bull Point; Antony House, the seat of W. H. Pole-Carew, Esq., whereat is preserved Holbein's portrait of Dr. Butts, Physician to Henry VIII; Ince Castle, the residence (*temp.* Charles II) of the Wit of Cornwall, Killebrew; St. German's Church, the site of Cornwall's ancient Cathedral, and Port Eliot (the ancient Priory); Trematon Castle, the residence of the Norman Earls of Cornwall; the late Brunel's master-piece, the Royal Albert Bridge at Saltash; Landulph Church; Buckland Abbey, the seat of Drake, the great circumnavigator; Maristowe; Cothele House; Pentillie Castle; Morwell Rocks; Harewood, the scene of the fair Elfedra's treachery; and other objects of interest in a trip of twenty miles by steamboat.

A steamer will be engaged to make short trips daily, and at stated hours, during the visit of the Association, thus enabling those members who may not be desirous of hearing the delivery of certain papers, to spend their time agreeably in viewing the rich scenery of the port of Plymouth.

Other excursions will be arranged, with the sanction of the Directors, etc., of the Railways—to Launceston Castle, the Ancient Cornish stronghold; to the Saxon Abbey at Tavistock; to Endsleigh Cottage; and to the wild and romantic scenery of Dartmoor.

A most interesting excursion into West Cornwall has also been planned to take place during the Association's visit.

*The Royal Institution of Cornwall*, under the presidency of Mr. D. J. Henwood, F.R.S., in order that opportunity may be given to the members of the British Medical Association for seeing the most noted and interesting objects in the extreme West of England under the most favourable circumstances, will make its annual excursion on Monday and Tuesday, the 14th and 15th of August. Penzance, the approach to which affords an excellent view of St. Michael's Mount, will be the place of rendezvous on the first day; and, after an inspection of this most westerly and mildest of British Winter resorts, the party will visit the Logan Rock and Land's End, concluding the day with an evening meeting at St. Just. On the morrow, the famous mine of Botallack will be explored, the fine northern coast line will be skirted, and the excursion will terminate in the picturesque neighbourhood of St. Ives, in time for the return journey to Plymouth. The line of route presents a great many remarkable objects of antiquity, especially primeval ones.

**ANNUAL MUSEUM.**—The "Annual Museum" of this Association will be open during the four days of the meeting, for the exhibition of:

1. The latest inventions in medical and surgical instruments and appliances of every kind. Also, for the special exhibition of ancient and modern fracture apparatus, or diagrams of such, thus setting forth the history of the treatment of fractures from the earliest records down to the present day.

2. New drugs and their preparations.

3. New articles of diet for invalids.

4. Pathological Specimens; also photographs, casts, etc., illustrating disease.

5. New works on medicine, surgery, etc.
6. Models or drawings of any object of professional interest not included in the above list.

*Notice to Exhibitors.*—Application should be made as soon as possible; at the same time giving a list of the objects to be exhibited, and mentioning the space required. All objects sent must have a description attached. Parcels for the Museum should be addressed—"British Medical Association, the Assembly Rooms, Royal Hotel, Plymouth; care of H. Greenway, Esq." They must be delivered on or before July 31st, and be removed within three days after the termination of the meeting. Expenses of carriage and all risk must be borne by the exhibitors. All instruments and other articles intended for the Local Museum will be conveyed at owners' risks for *half the usual fares* on the Bristol and Exeter, South Devon, and Cornwall lines of railway. A card, bearing the name and address of the exhibitor, must be enclosed in each package, ready to be fixed on the outside. All communications respecting the Museum to be addressed to "Henry Greenway, Esq., Surgeon, Plymouth", the Secretary for that department.

*PAPERS.*—The following papers have been promised.

C. Barham, M.D. 1. Diseases of Plymouth during the Second Quarter of last Century (1725-1750). 2. Diseases of Cornish Miners.

Tilbury Fox, M.D. 1. Hydroa. 2. A Note on Phtheirioid, erroneously styled Prurigo.

J. Crichton Browne, M.D. Syphilis and Insanity.

J. Althaus, M.D. Paralysis of the Bladder, and its Treatment by the constant Galvanic Current.

T. J. Austin, M.R.C.S. Medical Electrification.

Thomas Littleton, M.B. The Effects of Submarine Descent on Man, and the Limits of his Capability.

William Roberts, M.D. Intemperance as a Cause of Chronic Bright's Disease.

W. H. O. Sankey, M.D. The Relation and Diagnosis between General Paresis and Locomotor Ataxy.

D. De Berdt Howell, F.R.C.S. 1. The different Therapeutic Indications of Rheumatism and Neuralgia: with Remarks on Rheumatism as a Sequela of Diphtheria. 2. Uterine Truss or Support for *Post Partum* Hemorrhage.

George Southam, F.R.C.S. Excision of the Tongue.

T. H. Bartlett, M.B., F.R.C.S. Splint for Excision.

Edward Lund, F.R.C.S.—1. On Antisepticity in Surgery. 2. Apparatus for Syringing and Irrigating Wounds.

Furneaux Jordan, F.R.C.S. 1. On the Extension of Inflammation from the Epididymis to the Urethra: with Cases. 2. Self-holding Forceps for tying Arteries.

Thomas Beatty, M.D. 1. Fibro-cystic Disease of the Uterus. 2. The Radical Cure of Retroflexion of the Uterus.

Robert Barnes, M.D. Hypertrophic Elongation of the Cervix Uteri.

J. Braxton Hicks, M.D., F.R.S. 1. A Rare Form of *Post Partum* Hemorrhage. 2. The Reduction of Inversion of the Uterus: illustrated by six Cases.

E. J. Tilt, M.D. Hysteria, and the various ways in which it has been viewed by Pathologists.

A. Meadows, M.D. The Treatment of Fibrous Tumours of the Uterus.

J. G. Swayne, M.D. Treatment of Hemorrhage arising from Retention of the Secundines after Abortion.

Thomas Underhill, M.D. The Treatment of certain Cases of Placenta Prævia and of *Post Partum* Hemorrhage.

J. G. Davey, M.D. Jenner and his Teachings.

Dr. Merrifield, Ph.D. The Meteorology of Plymouth for the last six years.

Cornelius Fox, M.D. The Estimation of Atmospheric Ozone by means of Aspirators and Acids.

J. W. Eastwood, M.D. Alcohol in Health and Disease.

R. Elliot, M.D. Life-Insurance Offices and Medical Fees.

William Oyle, M.D. Medical Reform personal, not parliamentary.

V. Jagielski, M.D. Kouniss: a Dietetic Remedy.

Gentlemen desirous of reading papers, cases, or other communications, are requested to forward the titles to the General Secretary, or to one of the Secretaries of the Sections in which the paper is to be read. All papers should be forwarded to one of the above named officers on or before the 1st of August.

No paper must exceed twenty minutes in reading; and all subsequent speakers must not exceed ten minutes.

All speeches at the General Meeting must not exceed ten minutes each.

T. WATKIN WILLIAMS, F.R.C.S., General Secretary.

13, Newhall Street, Birmingham, July 15th, 1871.

## YORKSHIRE BRANCH.

THE annual meeting of the above Branch will be held at the Infirmary, Bradford, on Wednesday, 26th July, at 2.15 P.M.; R. H. MEADE, Esq., President, in the Chair.

The dinner will take place at the Victoria Hotel, at 5 P.M. Tickets (exclusive of wine), 7s. each.

Gentlemen having papers or cases to communicate, or who intend dining, are requested to send an early intimation to the Secretary, so that the necessary arrangements may be made.

W. PROCTER, M.D., *Honorary Secretary.*

York, July 12th, 1871.

## NORTH WALES BRANCH: ANNUAL MEETING.

THE twenty-second annual meeting of this Branch was held at the Castle Hotel, Ruthin, on Tuesday, July 4th, under the presidency of J. R. JENKINS, M.D. There were also present twelve members and one visitor. Several letters were received and read from members regretting their inability to attend.

*New Members.*—The following gentlemen were duly elected members; viz., Lewis Jones, L.R.C.P. Edin., Menai Bridge; Francis Manisty, Esq. (Surgeon-Major H.M. Indian Army), Gresford, Denbighshire; and H. J. Lloyd, L.R.C.P. Ed., Barmouth, Merionethshire.

*President's Address.*—The President delivered an interesting and eloquent address, which was heartily applauded, and for which an unanimous vote of thanks was accorded.

*Report of Council.*—The Secretary read the following report.

Your Council have the pleasure of stating that the North Wales Branch continues steadily to increase. The value of the Association in the many advantages attaching to it is becoming more and more recognised; and the high scientific position it has attained is at once a proof that it has taken a firm hold upon the professional mind of the many. And although very prosperous, it would be well to continue using our influence in inducing medical men of respectability to join our Society; and as a step in some measure to attain this, prospectuses of the objects of the Association with forms of application for admission to membership have been again recently posted to all in the northern principality whose names can be reached through the *Medical Directory*. The North Wales Branch having grown to a larger proportion, it is now entitled to one additional representative upon the General Council of the British Medical Association.

It is much to be regretted that the question of an amendment of the Medical Act of 1858 has been again postponed. Your Council adhere to the principles of the Bill as shadowed forth by the Reform Committee of our Association. They believe it is the only one that will satisfy the wishes of the great majority of the profession, and they ardently hope that all parties will agree to urge upon Government the desirability of settling the matter in the next session.

The Royal Sanitary Commission have at length issued their report, and appended to it a very important "memorandum," which refers to the establishment of a system of sanitary laws under a minister of health. This measure will probably be introduced into Parliament next session, and no doubt will give rise to a great deal of discussion. It is certain, if it become law, to place *State Medicine* in a very prominent and conspicuous place.

With feelings of the deepest regret your Council desire to advert to the loss this Branch has sustained in the awfully sudden and melancholy deaths of Mr. T. Francis Edwards of Denbigh, who was very creditably filling the office of President for 1870 and 1871; and Dr. Owen Roberts of St. Asaph, whose name was familiar not only to every member of this Branch, but to numerous others in the British Medical Association, of which he was an old member, and of which he strove to increase the usefulness and success with earnestness and zeal, combined with sound practical knowledge and genial character.

Your Council are happy to say that the Treasurer reports very favourably upon the financial state of the Branch.

Upon the motion of Mr. EYTON JONES (Wrexham), the Report of Council was agreed to, and ordered to be entered in the Minutes of the Branch.

*Vote of Thanks.*—Dr. HUGHES (Denbigh) moved a vote of thanks to the officers and Council of the Branch for the past year for their kind services, which was cordially assented to.

*President's Address for 1872: Place of Annual Meeting.*—It was moved by Dr. WILLIAMS (Mold), and seconded by Mr. EYTON JONES, and unanimously carried—"That Richard Chambers Roberts, Esq., of Ruabon, be President-elect for 1872, and Bala the place for the annual meeting for that year."

*Council of the Branch.*—Dr. TURNOUR (Denbigh) moved, and it was agreed to—"That the following members constitute the Council of the Branch for next year; namely, T. Taylor Griffith, Esq., E. Williams, M.D., and T. Eyton Jones, Esq. (Wrexham); W. Jones, Esq., Ruabon; W. Williams, M.D., Mold; and J. R. Walker, Esq., Corwen."

*Representatives in the General Council.*—It was moved by Dr. WILLIAMS (Mold), and seconded by Mr. TURNER JONES (Denbigh), and unanimously carried—"That the following members represent the Branch in the General Council of the British Medical Association:—A. E. Turnour, M.D., Denbigh; T. Taylor Griffith, Esq., Wrexham; and E. Williams, M.D., Wrexham."

*Representative in the Parliamentary Committee.*—Upon the motion of Dr. HUGHES (Denbigh), seconded by Mr. LODGE (St. Asaph), Thomas Eyton Jones, Esq., Wrexham, was elected the Parliamentary Committee Representative of the Branch.

*Intermediate Meeting for 1872.*—It was moved by Dr. TURNOUR, seconded by Mr. R. DAVIES (Llanfairtalhairn), and unanimously carried—"That Wrexham be the place for holding the next intermediate meeting."

*Secretary and Treasurer.*—Mr. D. Kent Jones (Beaumaris) was re-elected Secretary; and Mr. G. Turner Jones (Denbigh) was re-elected Treasurer for next year.

*Subject for Discussion at the Annual Meeting.*—Mr. EYTON JONES proposed, and it was duly seconded and carried—"That a medical subject, selected by the Council at a previous Council meeting, be introduced by the President in his annual address, with a view to its discussion by the members."

*Papers, Cases, etc.*—1. Avulsion of the Arm: Recovery. By J. R. Jenkins, M.D., President. The young man was brought into the room and the parts shown to the meeting.—2. Excision of the Elbow-Joint. By T. Eyton Jones, Esq., Wrexham.—3. Entire loss of Arm. By A. E. Turnour, M.D., Wrexham.—4. General Paralysis where there was a Growth of Bone between the Membranes of the Brain, without any attachment to the Skull. By G. Turner Jones, Esq., Denbigh.—5. Aneurism of the Posterior Tibia. The preparation was exhibited. By E. Shelton Jones, Esq., Denbigh.—6. Gun-shot Wound. By W. Williams, M.D., Mold.—7. Extrauterine Fœtation. By T. Eyton Jones, Esq., Wrexham.—8. Fracture of the Arm, in which no union of bone occurred. By J. R. Jenkins, M.D.—9. Dislocation of the Wrist in a boy aged 12. By T. Eyton Jones, Esq.—10. Compound Comminuted Fracture of Thigh. By J. R. Walker, Esq., Corwen.

*Dinner.*—All the members, after a pleasant stroll through the principal places of interest in the romantic old town of Ruthin, dined together, and spent a very agreeable evening.

## CORRESPONDENCE.

### SAYRE'S VERTEBRATED PROBE AND CATHETER.

SIR,—Many requests have been made from different surgeons and instrument-makers to examine my Vertebated Probe and Catheter for detecting dead bone in tortuous sinuses and for drawing off urine in cases of enlarged prostate, and also for use as a bent probe. I therefore send you a copy of the same, with a brief description for publication, if you think desirable.

It consists simply of a series of hollow silver disks, made a trifle smaller at one end than at the other, so as to fit into one another, like a pile of cups or tumblers. These are held together by a linked chain running through the series, and jointed nearly opposite each disk-insertion. This chain terminates in a square rod, which runs through the last disk, and is much larger than any of the others; and on the end of the small rod is cut a thread on which runs a small button-screw, which can make the chain tight or loose at pleasure. Of course, when the screw is turned back, the chain being lengthened, the disks fall away from each other, and the probe is as limber as a chain, capable of following any sinuosity into which it may be pushed. And by a few turns of the screw, the chain being shortened, the disks are drawn firmly together, so as to make a *solid* probe, which will give the concussion against carious or necrosed bone, the same as any other probe. A small slot is made in the cannula containing the screw, for the purpose of putting a small nut which regulates the tension of the chain, and thus prevents any possibility of applying sufficient force to break it. There are two fenestræ in the distal disk, for the purpose of drawing an oakum seton through deep sinuses and carious joints: this makes it also very useful as a catheter in cases of tortuous urethras from enlarged prostate. It is impossible to make a false passage with it;

and, as it is simply a series of ball-and-socket, or universal joints, it will follow any passage, however devious. By simply unscrewing the

steel bulb at the end, and inserting a bulb of porcelain, according to the suggestion of Nélaton, you have the most perfect bullet-probe that can be desired.

I have used this probe for more than seven months, and found it of the greatest advantage in the three several cases for which I have recommended it. I presented it to the New York Medical Society in July last; and an account of it will be published in their Annual Reports this year. But until now it has not been published to the profession, except in my public lectures at Bellevue Hospital, where I have used it frequently with great advantage. Mr. Weiss of the Strand is now making a number of them, by the order of Sir Alexander Armstrong, Director of the Medical Department of the Royal Navy; and I am happy to say that he has copied the model very admirably. Of course, like all other probes, this one requires to be made of different lengths and sizes.

To clean it, it is necessary to unscrew it at the end, and to remove the small screw at the slot in the cannula, when it will immediately fall to pieces. After washing, it is easily put together, just the same as a string of beads, only remembering to put the small end of the disk on the wire first; and, as each disk increases in length until the end, of course no error can occur in making them fit properly. The cut, together with this description, I think will make it plain. I am, etc.,

LEWIS A. SAYRE, of New York.

Bath Hotel, Arlington Street, W., July 14th, 1871.

### OUR LUNACY SYSTEMS.

SIR,—Carlyle has written, "But verily in these times, with their new stern Evangel, that Speciosities which are not Realities can no longer be, all Aristocracies, Priesthoods, Persons in Authority, are

called upon to consider"; and, in verity, we so-called alienists are having our turn now. If there are any "speciosities" in our system, the medical press seem determined that they "can no longer be"; and I see that in the *BRITISH MEDICAL JOURNAL* for July 1st, in a leading article under the above heading, you publish an elaborate condemnation of the present system. There is no doubt much that is true in your article; and as one of those therein put on their trial, I trust you will allow me to make a few observations.

Respecting the impropriety of the medical officers of asylums wasting their time and energies in the getting up of grand entertainments, I have as strong an opinion as yourself. In the asylum to which I am Superintendent, we have a dance once a week during the winter months; but it is managed entirely by the chief attendants; and the medical officers scarcely ever enter the room. So with all the other amusements got up for the benefit of the patients.

The part, however, of your article which will without doubt chiefly wound the susceptibilities of myself and my *confrères*, is that wherein you follow the fashion set of late by one or two other papers and sneer at our medical knowledge. You infer that a Medical Superintendent is, as a rule, behind an ordinary medical practitioner in the general knowledge of his profession, and that this is necessarily so, as he comes directly from the schools to engage in a specialty giving but few opportunities of practising general medicine. Now, sir, facts are stubborn things, and I wish to give you a few *à propos* of this.

I do not know how it may be across the Tweed, where the asylums, as a rule, are small; but here in England, where the asylum population is much larger, we see plenty of general medicine. In the asylum to which I belong, there is a population, counting sane and insane, of nearly nine hundred people of all ages. This is a good-sized village, and probably as large as the general run of country doctors' constituents. Looking through my case-books, I find that I have had to treat the following cases since this time last year; viz., strangulated hernia; fractures of tibia, fibula, ribs, and humerus; necrosis of tibia, femur, tarsal, and metacarpal bones; scirrhus of mamma; scirrhus of uterus; carbuncle; fevers; pneumonia; bronchitis; phthisis; morbus cordis; hæmatemesis; hæmoptysis; apoplexy; psosa abscess; lumbar abscess; nasal polypi; prolapsus uteri; prolapsus recti; various skin-diseases; uterine complaints; indigestion; diarrhoea; angina pectoris; iritis; catarract; etc. And yet I am told in your leading article that I have no opportunity of studying the ordinary branches of my profession.

Again, it is said that Medical Superintendents are so engrossed with their administrative duties that they have no time to devote to the advancement of the literature and practice of their profession. Surely people who make such statements cannot be aware that for more than twenty years we have maintained a high class quarterly devoted to the specialty, and which has been edited with acknowledged ability by asylum superintendents, and to which articles have been contributed on all sorts of subjects by the majority of English superintendents. Why, at the present moment, out of the little more than thirty English superintendents, fifteen are engaged in literary pursuits, and constantly contribute to the current medical literature of the day. And this list does not include such distinguished ex-superintendents as Bucknill, F.R.S., Lockhart Robertson, Maudsley, Boyd, Sankey, etc., whose fame is European.

No drug of any note is introduced to the medical world that is not eagerly seized upon, and extensively tried by asylum medical officers. We had probably used pounds of chloral before even its name was familiar to the majority of English practitioners. Bromide of potassium was first used extensively for epilepsy in asylums. The Turkish bath, the water treatment, the use in insanity of digitalis, subcutaneous injection of morphia, chloroform, Calabar bean, hydrocyanic acid, ergot, etc., have all been introduced to the notice of the profession by asylum superintendents; and when it is remembered how small our numbers are, surely, with the above fact before us, we cannot be justly accused of such utter disregard for the advancement of professional knowledge.

But, probably, the part of your article most open to objection is that in which you would appear to advocate the appointment of lay-superintendents, and deride the so-called moral treatment. Doubtless, under the shelter of moral treatment, much abuse has crept in; nevertheless it undoubtedly is the corner-stone of the non-restraint system, without which the whole edifice, so carefully built up by Pinel and Conolly, would totter to the ground; and, although probably its benefits have been much over-rated by enthusiasts, no man of any experience can deny its importance. It appears to me impossible that the thousand and one arrangements incidental to the management of an asylum can be made by anyone but a medical man. To give you only one or two instances. In cases of recent insanity, nothing is so likely to cause a relapse as the too early use of restraints. And, as we all know, a relapse in a case of acute insanity, frequently means chronic insanity or

dementia as sequel. How can a lay superintendent decide when it is safe to admit such visits. I have frequently known an injudicious letter from a friend do great harm. Most assuredly, carefully regulated and varied employments are very essential to the well-being of lunatics, and frequently promote a return to reason. But, to be used to any advantage, this requires an intimate knowledge of the cases such as only the doctor can have. Such examples could be multiplied *ad infinitum*, and yet you ask, "Is there anything more complicated in the management of a lunatic asylum than of a workhouse or prison?"

I am, etc.,

S. W. D. W.

## OBITUARY.

THOMAS HAWKES TANNER, M.D., M.R.C.P.

WITH deep regret we record the death of one of the most accomplished members of the profession. Thomas Hawkes Tanner, son of Thomas Tanner, Esq., for many years Secretary to the Army Medical Board, was born in London, on July 9th, 1824. He received his early education at Messrs. Wood and Thorowgood's school at Totteridge, and afterwards at the Charterhouse, where he met with a severe accident, which rendered his health delicate for many years. In 1843, he became a medical student at King's College, and served in its hospital as dresser to Mr. Simon and Sir William Fergusson, as well as clinical clerk to Drs. Guy, Arthur Farre, and Todd. In 1847, he passed the College of Surgeons, and in the same year was appointed House-Physician to King's College Hospital, became an Associate of King's College, and took the degree of M.D. at St. Andrew's. He commenced practice in Charlotte Street, Fitzroy Square, in the latter part of 1847, and was soon afterwards elected Physician to the Farringdon Dispensary. In 1850, he became a Member of the Royal College of Physicians, and in the course of the following year was appointed Physician to the Hospital for Women, Soho Square, and lectured on Forensic Medicine at the Westminster Hospital Medical School. In 1854, he published a *Manual of the Practice of Medicine*, which has run rapidly through several large editions. So popular has this work been, alike with medical men and with students, that in 1869 the sixth edition was published in two large volumes. Among other proofs of its success, may be mentioned the fact that this, together with five other works by Dr. Tanner, have had an extensive circulation in America, but without any remuneration either to the author or to the publisher. His chief works have been: 1, *Practice of Medicine*; 2, *On the Signs and Diseases of Pregnancy*; 3, *Manual of Clinical Medicine*; 4, *Practical Treatise on the Diseases of Childhood*; 5, *Memoiranda on Poisons*; 6, *Index of Diseases*; 7, *A Clinical Report on Cancer of the Female Sexual Organs*; and many articles and reviews contributed to the various medical journals. Throughout the wide range of their subjects, we notice an eminently practical tendency, and the style of a writer who holds firmly the conclusions at which he has arrived by clinical observation made during an extensive practice.

In 1858, Dr. Tanner, in concert with Dr. Tyler Smith, Dr. Rigby, and Dr. Graily Hewitt, took an active part in the formation of the Obstetrical Society of London, and acted as its Secretary from the time of its foundation until the close of 1863. He contributed several valuable papers to the volumes of *Transactions*, and was elected one of the Vice-Presidents of the Society on his retirement from the post of Honorary Secretary.

In 1860, Dr. Tanner was elected Assistant-Physician for the Diseases of Women and Children to King's College Hospital, and thereupon retired from office as Physician to the Hospital for Women, and resigned also his place as Lecturer on Forensic Medicine in the Westminster Hospital Medical School. While holding his appointment in King's College Hospital, which he resigned in 1863, Dr. Tanner lectured on Obstetrics to the class of midwifery pupils supported by Miss Nightingale. Since the date of his resignation, his private practice has been very extensive. In 1862, he removed from Charlotte Street to Henrietta Street, Cavendish Square. Previously to this, his career had not been so prosperous as many might imagine. He had fought an uphill fight, but always confident in his certainty of success. He had an excellent memory, a mind well cultured and richly stored; he had great literary power, as shown by his works, and was most orderly and accurate in every minutia. Few have stronger feelings than he had about the proper remuneration of medical men, but none have deeper sympathies with the poor; and, out of his six thousand registered gratuitous patients, numbers will feel that they have lost their best earthly friend. Dr. Tanner was a man of great taste, as all who may have seen his splendid library must have recognised.

In 1854, he had an attack of scarlet fever, which left evidence of

renal congestion. The necessary work and anxiety of a physician's large London practice never enabled him to lay by and eradicate the disease, and thus by degrees it crept on and began to tell on his general health. Scarcely had he completed and published his sixth edition of the *Practice of Medicine* when the disease (Bright's), which had been long smouldering, appeared with unmistakable clearness; and by degrees the state of his health became so serious that last April he determined to relinquish practice for a time and go to Brighton for complete rest and change. Uræmic symptoms came on shortly afterwards, and four weeks of great suffering put an end to this valuable life. He died at Brighton, on July 7th, two days before the completion of his forty-seventh year. He was married in 1859, and leaves a widow and four children. According to his express wish, he was buried (on Thursday, the 13th) at Highgate Cemetery, in the least ostentatious way possible. Many friends, who wished to pay their last tribute of respect, joined the relations at the cemetery, and followed him to his resting-place.

## UNIVERSITY INTELLIGENCE.

### UNIVERSITY OF CAMBRIDGE.

THE following gentlemen have been nominated Examiners for medical degrees during the ensuing academical year. *First M.B. Examination:* Coutts Trotter, M.A., Fellow and Natural Sciences Lecturer in Trinity College; W. P. Hiern, M.A., late Fellow of St. John's College. *Second M.B. Examination:* The Regius Professor of Physic (*ex officio*); John Wood, F.R.S., F.R.C.S., Professor of Surgery, King's College, London; J. R. Bradbury, M.D., Medical Lecturer in Downing College and Physician to Addenbrooke's Hospital. *Third M.B. Examination:* The Regius Professor of Physic (*ex officio*); Herbert Davies, M.D., late Fellow of Queen's College, Physician to the London Hospital; J. W. Ogle, M.A., M.D. Oxon, Physician to St. George's Hospital.

Dr. Barclay, Physician to St. George's Hospital, has been nominated Assessor to the Regius Professor of Physic.

## MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed their primary examinations in anatomy and physiology, at a meeting of the Court of Examiners, on July 18th; and, when eligible, will be admitted to the pass examination.

Messrs. G. Warner Bell, W. C. K. Foster, S. William Douglas, George R. Steil, and W. E. N. Erith (Students of University College Hospital); James Ritchie, Francis Imlach, H. Macdonald Church, and Edwin Hinchcliff (Edinburgh School); J. Christopher Irving, and J. Randall Burton (Guy's Hospital); Arthur J. Vousse, and Albert E. Kirby (Leeds School); Frederick W. Corry, and Francis Johnson (London Hospital); James H. Stowers (St. Bartholomew's Hospital); R. Campbell Fair (Canada); Matthew J. Fitzpatrick (Dublin); John D. Jennings (Birmingham School); and John B. Stuart (Liverpool School).

The following gentlemen passed on July 19th.

Messrs. Peter Bradford, Henry C. Lang, Harold Rugg, Oliver Barber, J. G. R. Symons, Richard St. M. Dawes, and Maurice Eskell (Students of University College); H. J. F. Groves, William Y. Davenport, Richard D. Hughes, Joseph H. Townend, Daniel Nunez, and Evan M. Boddy (Guy's Hospital); John M. Hart, W. C. G. Collins, G. T. B. Moffatt, R. Leymans Bridges, B.A. Oxon, and Lonsdale A. Holden (St. Bartholomew's Hospital); Charles Hartley (Charing Cross Hospital); and Charles F. Grindrod (St. Mary's Hospital).

The following gentlemen passed on July 20th.

Messrs. J. W. Greenwood, Daniel A. Sinclair, W. S. Mavor, E. Welchman, C. G. Johnson, G. E. Wherry (St. Thomas's Hospital); Herbert B. Blackburn, George E. Keer, J. Sutherland Wilkins, William J. Gard, and W. Jackson Heddy (Guy's Hospital); H. C. M. Gibson, Thomas P. Vawdrey, Edwin M. Redman (University College); Matthew A. Messiter, Charles Lakin, and Hyacinth D'A. Ellis (Birmingham); Rees R. Llewellyn, and W. A. Grogano (London Hospital); Arthur Kirkpatrick, and Robert F. Samuels (Liverpool School); T. W. F. Gray, and Montague Ford (Charing Cross Hospital); Francis E. Atkinson (St. Mary's Hospital); William Coulter (Belfast School); and Campbell W. Pridmore (Westminster Hospital).

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received their certificates to practise, on Thursday, July 13th, 1871.

Briggs, Henry Myddleton, Birmingham  
Lyons, Isidor Isaac, St. John's Wood  
Richards, George Pickering, Newman Street, Oxford Street  
Rix, Benjamin, East Meon, Hants  
Thornton, William Pugin, Canterbury  
Williams, Edward, Llandysyll, South Wales

The following gentleman also on the same day passed his first professional examination.

Garrard, William Arthur, Guy's Hospital

As Assistants in compounding and dispensing medicines.

Gould, Eli, Reddal Hill, near Dudley  
Holmes, Nathaniel W., Chorlton-on-Medlock  
Pollard, William, Wakefield

## MEDICAL VACANCIES.

THE following vacancies are announced:—

ABERFOYLE, Perthshire—Parochial Medical Officer.  
BIRMINGHAM and MIDLAND FREE HOSPITAL for SICK CHILDREN—Resident Medical Officer.  
BOURNEMOUTH GENERAL DISPENSARY—Resident Surgeon.  
BRADFORD (Yorkshire) INFIRMARY and DISPENSARY—Physician.  
BURY (Lancashire) DISPENSARY—Resident Medical Officer.  
CHARYNG CROSS HOSPITAL—Physician.  
DERBYSHIRE GENERAL INFIRMARY, Derby—Resident Assistant House-Surgeon; Two Dental Surgeons; Non-Resident Dispenser.  
FARINGDON UNION, Berks—Medical Officer and Public Vaccinator for the Buckland District.  
GAINSBOROUGH, Lincolnshire—Medical Officer of Health.  
GENERAL HOSPITAL and DISPENSARY for SICK CHILDREN, Bridge Street, Manchester—Resident Medical Officer.  
GUISBOROUGH UNION, Yorkshire—Medical Officer for the Danby District.  
HEREFORD GENERAL INFIRMARY—House-Surgeon.  
HUDDERSFIELD and UPPER AGBRIGG INFIRMARY—Physician; House-Surgeon.  
INFIRMARY for EPILEPSY and PARALYSIS, Charles Street, Portman Square—Physician.  
KILLALA, co. Mayo—Medical Attendant to the Royal Irish Constabulary.  
KING'S COLLEGE HOSPITAL—Assistant-Physician; Assistant Surgeon.  
LOUDOUN, Ayrshire—Medical Officer and Public Vaccinator.  
LOYAL EARL OF LONSDALE LODGE OF ODD FELLOWS, Bampton, Cumberland—Medical Attendant.  
METROPOLITAN FREE HOSPITAL, Devonshire Square—Assistant-Physician.  
MIDDLESEX HOSPITAL MEDICAL COLLEGE—Lecturer on Physiology, including Practical Physiology.  
NEUBURY UNION, Berks—Medical Officer for the Thatcham District.  
NEWCASTLE-ON-TYNE LYING-IN HOSPITAL—Visiting Surgeon for the Out-department.  
PLYMOUTH INCORPORATION OF THE POOR—Medical Officer for the Northern District.  
ST. PANCRAS—Dispenser for the Dispensary for Out-door Poor, King's Road.  
SANDAY, Orkney, Island of—Medical Officer.  
SEAMEN'S HOSPITAL (late *Dreadnought*)—House-Physician; House-Surgeon.  
SKIRLAUGH UNION, Yorkshire—Medical Officer for the Skirlaugh District and the Workhouse.  
WATERFORD UNION—Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the Kilmedden Dispensary District.  
WEST LONDON HOSPITAL—Junior Physician; House-Surgeon.  
WESTMINSTER HOSPITAL—Surgeon; Assistant-Surgeon.  
WIRRAL HOSPITAL and DISPENSARY for SICK CHILDREN, Birkenhead—Honorary Medical Officer.

## MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

BUCKLEY, Dr., appointed Medical Officer for the Clane and Timahoe North Dispensary District of the Naas Union, co. Kildare.  
DREW, John, M.B., M.C., appointed Medical Officer for the parish of Logie, Clackmannanshire.  
\*GARNHAM, J. Devereux, Esq., appointed Medical Officer to Nos. 2 and 11 Districts of the Lincoln Union.  
LOUGH, John Joseph, M.B., appointed Medical Officer for the Terman Dispensary District of the Balieborough Union, co. Cavan.  
MCCRAITH, Edward, L.R.C.P. Edin., appointed Medical Officer for the Mitcheltown Dispensary District of the Mitcheltown Union, co. Cork.  
MACFARLANE, Wm. D., L.R.C.P. Edin., appointed Medical Officer for the Carmunrook and Busby District of the parish of Mearns, Lanarkshire.  
MADDEVER, John C., M.D., appointed Medical Officer for the parish of Rothsay.  
PALFREY, James, M.D., appointed Physician-Accoucheur to the Out Patients at the General Lying-in Hospital, *vice* \*Alfred Meadows, M.D., resigned.  
\*SHEEN, Alfred, M.D., appointed Surgeon in Ordinary to the Cardiff Infirmary, *vice* J. R. Reece, Esq., resigned.  
SKINNER, S., M.D., appointed one of the Medical Officers to the Clevedon, Walton, and Tichenham Dispensary, *vice* \*Theodore Davis, M.D., resigned.  
STITT, Adam, L.F.P.S. Glasg., appointed Medical Officer for the parish of Lochmaben, Dumfriesshire.  
STONE, Hugh B., M.B., appointed Medical Officer for the Durrow Dispensary District of the Abbeyfeich Union, Queen's County.  
SWAN, R. Jocelyn, M.R.C.S.E., appointed Medical Officer and Public Vaccinator for the No. 2 District of the Northleach Union, Gloucestershire.  
SYMES, Edmund West, M.B. Edin., elected Senior Resident Medical Officer to the Leeds Public Dispensary, *vice* \*J. M. Fothergill, M.D., resigned.  
\*WORKMAN, Charles J., M.D., appointed Ophthalmic Surgeon to the Teignmouth, Dawlish, and Newton Infirmary.

LINCOLN MEDICAL SOCIETY.—This society held its ninth annual summer meeting at Drinsey Nook, near Lincoln, on July 11th. The President, Mr. F. D. Walsh, opened the meeting with an address on subjects of general interest to the profession, and concluded with a short paper on paralysis of the insane. New members were made; and Mr. D. J. Garnham of Lincoln was unanimously elected President for the next season. The meeting was brought to a close with a vote of thanks to the honorary secretary, Mr. Male, of the Lincoln County Hospital. The members afterwards dined *al fresco*, and a pleasant afternoon was spent.

## OPERATION DAYS AT THE HOSPITALS.

**MONDAY** ..... Metropolitan Free, 2 P.M.—St. Mark's, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.

**TUESDAY** ..... Guy's, 1.30 P.M.—Westminster, 2 P.M.—National Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.

**WEDNESDAY**..... St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.

## NOTICES TO CORRESPONDENTS.

**ALL Letters and Communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen Street, Lincoln's Inn Fields, W.C.**

**CORRESPONDENTS** not answered, are requested to look to the Notices to Correspondents of the following week.

**TO PURCHASERS.**—To insure attention, it is requested that all orders sent to the Office for extra copies of the JOURNAL, be accompanied with *halfpenny* stamps for the amount.

**WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.**

**CORRESPONDENTS**, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

**MR. STEELE (Bristol)** will find an answer to his communication in Dr. Sayre's letter this week.

**DR. GOODHART (London).**—The interesting case forwarded for our hospital reports, shall be inserted as early as possible. In consequence of the large amount of Association matter on hand at this time, its appearance may be delayed for a short time.

**GANGLION.**—The note arrived, and will appear probably next week.

**THE gentleman** who took a hat by mistake at the meeting of the Metropolitan Counties Branch at Windsor on Friday last is requested to return it to Mr. Coles, hatter, Strand, where his own has been since Saturday.

**A MEMBER OF THE BRITISH MEDICAL ASSOCIATION**, at the ensuing meeting to be held at Plymouth, could pay a visit to the Fowey Cottage Hospital. Dr. Arthur Davis will afford every information on the subject.

**MR. T. K. GRAY (Carlisle).**—In type, but delayed by pressure of matter.

## MARINE PHOSPHORESCENCE.

**DR. DALTON** of Bournemouth writes to us that, while on board the ship *Carlisle Castle*, on May 18th, 1871, in latitude 0.50 N., longitude 29.15 W., the sea was observed after sunset to become highly luminous. The appearance extended to the horizon in every direction, every little wave giving off the phosphoric lustre in a beautiful manner. On May 10th, during the day, the sea was again dark, and the sea water was found, by the aid of a microscope, to contain innumerable animalcules, as reported by the captain. At darkness, the same brilliant sight was again visible, the sea rolling gently with a fiery surface, and the horizon appeared as at twilight. At 3 P.M. the ship suddenly passed out of this luminous sea into a dark sea, the line of demarcation running east and west, so far as could be seen. The sky was clear, and the weather fine. On Saturday, May 20th, the water had assumed its usual blue colour. From January 1862, to January 1869, Dr. Dalton says he passed at sea as surgeon to a ship, with the exception of an interval of six months between his two voyages to the Pacific Ocean. Since his retirement from practising at Cheltenham, he has visited Australia and circumnavigated the globe. In all his experience at sea, he never before saw the sea so generally luminous; and this was the feeling of all on board with whom he conversed on this subject.

**DR. CHARLES BROWNE (Wakefield)**, **DR. TAYLOR (Penrith)**, and **MR. ROBERTS (London)**, shall have their wishes complied with if possible.

**MR. WORTHINGTON (Worthing).**—With pleasure, so soon as space allows.

**WE have to thank many correspondents** for their kind communications with reference to the subjects raised by Mr. Gamgee's correspondence. We suggest that the further consideration of the matter will best be had at the Annual Meeting, when the report of the Council on the general subject will be in the hands of the members, and all opinions can be expressed after a deliberate review of the facts.

**A MEMBER (Leicester).**—The diplomas mentioned are sufficient.

## CORRECTION IN THE PROGRESS MEDICAL SERVICE.

**SIR,**—In your JOURNAL of April 15th, you kindly inserted a letter of mine regarding a difference existing between the Board of Guardians and myself. In reply to their advertisement, it is to be regretted an applicant has been found duly qualified, with very good testimonials, late Assistant Medical Officer at a County Asylum, and Resident Medical Officer of an Infirmary, who is willing to undertake the duties at the miserable salary mentioned in my letter. I send these particulars for your perusal, and to make any comment upon them that you may feel disposed. The ungracious manner in which Boards of Guardians treat their medical officers is little to be wondered at. I am, etc., MAURICE G. EVANS. Narberth, June 24th, 1871.

**NOTICE TO ADVERTISERS.**—Advertisements should be forwarded direct to the Printing-Office, 37, Great Queen Street, W.C., addressed to Mr. F. H. HEATHCOTE, not later than *Thursday*, twelve o'clock.

## THE ANNUAL MUSEUM AND LIMB-SUSPENDERS.

**SIR,**—Allow me to draw attention to my letter in a contemporary of last Saturday, in reference to Mr. Gamgee's communication on a limb-suspender. I wrote that gentleman in April last, asking him to assist in the special exhibition at our Museum; and he has not troubled himself to reply. I also brought before his notice a photograph of my limb-suspender, and mentioned its advantages. I wonder whether he and the Birmingham builder would have brought out a suspender at this moment but for my communication? Mr. Gamgee speaks in a very disparaging tone of the suspenders made by the London makers. Plymouth, July 17th, 1871. I am, etc., H. GREENWAY.

**MIDWIFERY EXAMINATIONS.**—From our advertising columns, it will be seen that the next examination for the "L.M." of the Royal College of Surgeons will take place on Monday, the 31st instant. In all probability, this will be the last occasion of granting that license, owing to the conjoint examination of the two colleges.

**J. H.—MR. QUAIN** will move, at the next meeting of the Council, that a Committee be appointed to investigate the expenses of the College in all its departments, and report thereon, with a view to the diminution of expense where practicable.

**BIBLIOPOLY.**—The Libraries of the Royal Medical and Chirurgical Society, and of the College of Surgeons will be closed at the time mentioned; at the latter institution during the month of September.

**DR. CORNELIUS FOX (Scarborough).**—In publishing letters concerning vaccination we are influenced not by the partial considerations which Dr. Fox suggests, but by the limits of space and the original value of the communication. We have had in type for several weeks an extremely able communication by Dr. A. B. Steele, of Liverpool, on the other side of the question to that assumed by Dr. Fox, but have been compelled by pressure on space to postpone it week after week. The publication of the letters of Mr. Startin and Dr. Snow Beck has shown that we are not open to the charge which Dr. Fox improperly insinuates. We will, if possible, publish also Dr. Fox's letter.

## THE ADMINISTRATION OF CHLOROFORM.

**DR. THOMAS CATTALL** writes to us that he was the first to promulgate the principle in the administration of anesthetics, which was applied by Mr. Clover in devising his improved chloroform apparatus in 1862. He quotes a letter which he published in a contemporary in 1860, in which he expressed the opinion "that no anesthetic agent should be allowed ingress to the lungs of a higher specific gravity than the air we breathe." He said further in the letter, that, to carry the principle into operation, an arrangement was required "which will permit the specific gravity of the vapour to be lowered to the standard in question, and uniformly maintained during the process of inhalation, which will allow of each vapour being inhaled directly intermixed with a given proportion of free oxygen or in connection with another compartment containing it."

**WE are indebted to correspondents** for the following periodicals, containing news, reports, and other matters of medical interest:—The New York Medical Gazette, July 15th; The New York Medical Record, July 6th; The Boston Medical and Surgical Journal, July 6th; The Madras Mail, May 8th; The Shield, July 15th; The Philadelphia Medical Times, June 28th; The Philadelphia Medical Independent, July 1st; The Birmingham Morning News, July 17th; The Daily News, July 17th; The Surrey Comet, July 15th; The Western Daily Mercury, July 13th; etc.

## COMMUNICATIONS, LETTERS, ETC., have been received from:—

**DR. T. L. BRUNTON**, London; **THE REV. DR. HAUGHTON**, Dublin; **MR. T. WATKIN WILLIAMS**, Birmingham; **MR. W. H. SPENCER**, Preston; **DR. G. E. DAY**, Torquay; **DR. CRAWFORD**, Stafford; **DR. J. WILKIE BURMAN**, Wakefield; **DR. J. B. BRADbury**, Cambridge; **DR. HEATON**, Leeds; **DR. ADAM ROBERTS**, Coldstream; **MR. T. E. CLARK**, Clifton; **DR. A. MACKINTOSH**, Callington; **DR. G. H. KIDD**, Dublin; **OUR EDINBURGH CORRESPONDENT**; **MR. C. H. MAY**, London; **DR. W. WHITELAW**, Kirkintilloch; **MR. H. DUNCALFE**, West Bromwich; **A MEMBER**; **DR. SAYRE**, New York; **DR. ## CLINICAL LECTURES

ON

## MENTAL AND CEREBRAL DISEASES.

By J. CRICHTON BROWNE, M.D., F.R.S.E.,

Medical Director, West Riding Asylum; Lecturer on Mental Diseases to the Leeds School of Medicine; etc.

## II.—HYSTERICAL MANIA.

GENTLEMEN,—Your reading and observation must already have taught you something of the intimate correlations which subsist between the brain and the reproductive organs; and your experience in the wards of our asylum will frequently illustrate these correlations, and impress them upon you. Your study of mental phenomena in health and disease will speedily convince you that they are influenced in no slight degree by the sexual functions, and that they exercise a reciprocal control. Jenner and Hunter showed that the ovaria and testes in birds enlarge during the breeding season, when their highest instinctive efforts are achieved, and waste again at the end of that season, when they sink down to a lower level of life. The period of the rut in animals is accompanied by mental activity, which borders upon morbid excitement, while the gravid state of the uterus in females of our own species may lead not merely to change of temper, morbid appetites, and capricious eccentricity, but to chorea, somnambulism, amaurosis, convulsions, or mental derangement. On the other hand, a condition of mental agitation may derange the menstrual discharge, and ideas may modify the nutrition of the sexual apparatus. A very striking illustration of the power of a persistent delusion to induce changes in the vascularity of the uterus and ovaries was afforded lately by I. N., who is still an inmate of Ward 22. This woman, about whose exact age there seems to be some doubt, but who is certainly over fifty, was received here from Leeds on June 4th, 1870. She is the mother of five children, the youngest of whom is fifteen years old, and was stated by her relatives to have passed through the change of life some four years ago. When admitted here she announced that, notwithstanding her age and other seeming improbabilities, she was two months advanced in pregnancy; and arguments and assurances, after a careful examination, failed to shake her belief in this fact. She very cogently remarked that she knew what it was to be in the family-way better than the doctors; and for seven months, in spite of the absence of every recognised sign of her alleged condition, held firmly to her singular belief. At the end of that time—precisely nine months from the date of conception which she had fixed—she intimated that labour-pains had commenced. She went to bed, and insisted on observing all the formalities of the lying-in room. She had a dose of castor-oil and some gin; she had a sheet fastened to the top of her bed, and by that she held, at stated intervals, gradually diminishing in length, when she cried out as if in the pains of labour, manifested all the appearances of suffering, and broke out in profuse perspiration. Nothing could dislodge the idea that she was about to be delivered of a fine child. This went on for four days, when the abdomen became tympanitic, when she looked as if really exhausted by a protracted labour, and when—and this is the remarkable fact—menstruation recommenced after an interval of four years. The vivid belief had actually modified the circulation in the pelvic viscera, and caused them to resume a function which had been abolished in the order of nature.

Now, it is in the close and subtle relation between the brain and the pelvic viscera, which is so curiously exemplified in the case just described, that the source of hysterical mania, which we are to-day to consider, must be sought. The one constant element in all cases of this disorder is a disturbance of the balance of action and reaction which subsists between the nervous centres and the reproductive organs. In every instance of it the brain and the uterus have their functions conjointly deranged; for, whatever may be true of simple hysteria, as encountered in general practice, it would not hold good of hysterical mania, as seen in asylums, that it may accomplish its whole course in the cerebrum without involvement of the generative system. The morbid process may originate in the brain or in the uterus; but in either case it spreads from the one to the other, and upsets that harmony and just proportion of function in which health consists. The mental affection is the more prominent feature in the complaint; but the uterine factor is not wanting, and it is the latter that confers upon it its distinctive characters. All forms of ordinary hysteria have some mental commotion or enfeeblement associated with them; and, indeed, so constantly is this the case that hysteria might not improperly be regarded as a men-

tal disease. The incontinence of the emotions, the moral obliquity, the towering egotism, the positive delusions, which characterise it, are common to it and to some recognised forms of insanity, and a slight increase in their intensity and persistency would amount to recognised mental derangement. But the singular fact is, that this slight increase very rarely takes place. Hysterical mania does not, as a rule, occur in girls who have been most acutely hysterical. It much more frequently attacks those who have manifested only hysterical tendencies. True, it does occasionally happen that, at the close of an hysterical paroxysm, mania is developed. Much more commonly, however, the mental disorder which we are now discussing presents itself in those who have only exhibited very mild hysterical phenomena.

It is clear, therefore, that hysterical mania is not a mere exaggeration of the hysterical state. What additional element, then, is involved in its constitution? To this question I have little hesitation in answering that the insane temperament is that which, when combined with the hysterical temperament, determines the development of hysterical mania on the occurrence of an appropriate exciting cause. My observations have convinced me that a distinction requires to be drawn more accurately than has hitherto been done between the nervous temperament, the hysterical temperament, and the insane temperament; and that it is in the coexistence of the last two of these that the risk of hysterical mania resides. Where the hereditary taint of madness is present, and betrays itself in peculiarity of thought and feeling, and where at the same time the exalted sensibility and mobility of hysteria are also present to some extent, there is the appropriate soil for the growth of hysterical mania. If, under such circumstances, any irregularity of menstruation lower vital power and augment irritability, then almost inevitably we have hysterical mania. Or if, under such circumstances, intense annoyance, or distress, or disappointment, be encountered, then again almost inevitably we have hysterical mania.

Verification of these statements is easily obtained in the history of cases which have lately passed through this asylum. Some of you must remember S. H., who was an inmate of Ward 34, and who went home on February 17th. This girl was admitted on the 2d June, 1870, and was then seventeen years of age. She was a weaver from Bradford. Her mother had been once temporarily insane and confined in an asylum, and a brother had also been for a brief period out of his mind. She had always been a hard-working girl, and had latterly overtaxed her strength by undertaking many household duties in the evening after her return from the mill, in order to help her mother, who was an invalid. Although she had never before exhibited any signs of mental disease, she had always been excitable and susceptible, and prone to blended outbursts of laughter and tears, which had ended occasionally in choking and twitches. Fourteen days previously to her reception here, her youngest brother, to whom she was fondly attached, died after a short illness. The bereavement preyed upon her mind. She was very quiet in her manner, and desired to be left alone, until ten days after the event, when suddenly, on the 28th May, grave gave way to gay, the solemn to the ludicrous; she became hilarious and excited. In a few hours, the excitement had passed into mania. Dances, gesticulations, snatches of songs, and ribald jests, occupied the night, and, with few and short interruptions, the next three days, until she was removed to this hospital. When admitted here, her condition was typical of hysterical mania. She was of middle height, with brown hair, dark-blue eyes, and a pleasing and animated expression of countenance. There was none of the facies hysterica in her comely visage. She was exuberantly garrulous, chattering incoherently on a variety of topics, betraying no fixed delusions, but seizing upon whatever was said to her, and spinning it into the tangled and knotted thread of her discourse. She was quick to comprehend whatever was addressed to her, and her will had evidently not lost all dominion over her conduct, for, when spoken to in a sharp and authoritative manner, she could remain quiet for a few seconds, until the impulse to energeise through the vocal apparatus became too strong for her, and broke out once more in voluble utterances. Her emotions were tinged with eroticism. She attempted to embrace the medical officers, and referred perpetually to love and friendship in phraseology which was not after the manner of Plato. She laughed immoderately and sang vigorously from time to time. Her pupils were of average size and sensibility; her skin was moist, her muscles soft and flaccid, and her tongue clean. The heart and lungs were healthy, the mucous membranes were pale, and the body, though plump, gave general indications of anæmia. She was suffering from leucorrhœa. S. H. remained here for eight months, and twice suffered relapses, after having been apparently restored to health. For the first four months there was amenorrhœa, with leucorrhœa; and, indeed, permanent recovery did not take place until the menstrual function was re-established in a proper manner.

Now you will have noticed in this case of S. H. an inherited predis-

position to madness, an innate tendency to hysteric perturbations, a great grief, a weak state of health, and menstrual irregularity—in fact, all the conditions which I have enumerated as most important in the etiology of this disease. Lest, however, you should think the case of S. H. in any way exceptional, I shall direct your attention to that of A. H., only lately discharged from Ward 30. This girl, a domestic servant from Dewsbury, twenty-one years old, was admitted on March 2nd, 1871. She was reputed to have had an aunt insane, and to have been always of a peculiar and irritable temper, which led her to go into service in opposition to the wishes of her relatives, her father being a farmer in a comfortable position. When fourteen years of age, she had what is called “a fit”, probably a paroxysm of hysteria; and two years later she suffered from rheumatic fever, which left a loud systolic *bruit* at the base of the heart. During February of this year, a lover, who had been long devoted to her, withdrew his attentions, and thus wounded her pride and her affections. On the 26th of that month, after some days of brooding, she became odd in her manner, and made numerous statements which were known to be erroneous; and on the 28th an attack occurred which those around her at once pronounced hysterics, and in which there were laughter and sobbing, and muscular tremor and startings. From this attack she emerged in a state of mania, talking loudly, incessantly, and incoherently, and then crying out “William” for hours together. When admitted here on the 2nd of March, she presented the symptoms of hysterical mania in as characteristic a way as did S. H., to whom we previously referred. Now in this case also you must remark that the causes in operation were almost precisely those which existed in the case of S. H., and correspond closely with what I have laid down as the essential conditions for the production of hysterical mania. The one condition wanting was the menstrual irregularity; and this was absent only at the outset of the attack, for during its progress the menses were suppressed. As the result of a large experience of hysterical mania, I am satisfied that it is without exception preceded or accompanied by some derangement of the reproductive system, the existence of which is most frequently indicated by alteration or obstruction of the monthly discharge. Even where, however, neither amenorrhœa, leucorrhœa, nor menorrhagia can be discovered, other signs of disorder in the functions of the reproductive organs can be found, if carefully looked for. I well remember a girl named E. B., labouring under hysterical mania, in whom no disturbance of the sexual system could be detected until, towards the close of the attack, distinct irritability of one breast came on. While the excitement lasted, and even after it had subsided, the left mamma was swollen, turgid, and the seat of uneasy sensation, aggravated by pressure, and reaching sometimes to exquisite pain. The consensus existing between the mammae and the uterus, indicated by a variety of facts such as these—that a secretion of milk has been produced by irritation of the womb and the catamenia by poulticing the breasts—entitles us to conclude that there was in this case some uterine or ovarian condition corresponding to the irritability of the mamma, and that there may be in other cases of hysterical mania a disorder of the reproductive system without any very conspicuous outward manifestation. We must bear in mind that irritation or inflammation of an ovary, or ulceration of the cervix uteri, may proceed to some extent without interfering with menstrual regularity, or giving rise to any symptoms which would directly suggest their presence; and we must not, therefore, hastily infer that there is no involvement of the reproductive system in any case of hysterical mania because patent signs of such involvement are not at first discoverable. Masturbation and venereal disorders occasionally cause that irritation of the reproductive system from which hysterical mania results.

To complete your acquaintance with the causes of hysterical mania, I have only now to add that it occurs only in the female sex, and almost exclusively between the ages of fourteen and thirty, and is much more frequent among the single than the married, and in the upper than in the lower classes of society. I know of no form of mental disease thoroughly analogous to it occurring in males. Insanity due to masturbation and sexual excitement in them, although sometimes described as hysterical mania, admits of another classification, and does not conform to our knowledge of that well marked disease. During the last five years there have been only two cases of distinct hysterical mania in this asylum in which the age exceeded thirty. In eighteen cases of which I have drawn up reports, the average age was twenty-one years. This fact in some measure accounts for the larger proportion of single women attacked by hysterical mania, as it is clear that the invasion of the disease most often takes place before the age at which women commonly marry in this country. The hothouse education and artificial and luxurious modes of life prevalent amongst the upper and middle ranks are of course conducive to the evolution of hysterical tendencies. Even in a pauper asylum, the victims of hysterical mania

are seldom without some touch of refinement, some traces of sentiments rather superior to their social lot.

You will have gathered from what I have already said that hysterical mania is a much simpler and better defined disease than ordinary hysteria; and you will be correct in that inference. It is not a mimic nosology, an epitome of morbid action, nor a Protean affection assuming a hundred strange shapes for the very love of lying. It does not puzzle nor baffle diagnosis. It is a tolerably straightforward disorder, and as a rule may be readily recognised. The additional conditions superimposed upon hysteria, when hysterical mania occurs, materially restrict its wanderings, and facilitate its observation and treatment. They cut off innumerable divergencies, render impracticable many disguises, and make its true character much more apparent. But do not imagine therefore that the whole relations of hysteria to insanity are of a comparatively simple character, and that physicians who treat mental diseases are exempt from the worries and perplexities which in general practice hysteria begets. Hysterical mania is not the only form under which hysteria occurs in lunatic asylums. On the contrary, there are several other varieties of insanity which are occasionally complicated by hysterical symptoms, and which may partly originate in hysteria. At the present time, you may see in Ward 24 J. M., and in Ward 26 M. M., who are both labouring under dementia and indubitable epilepsy, and who both also suffer from unquestionable hysteria. In both of them, the hysteria preceded the epilepsy, and seemed to deepen into it. In one, it betrays itself in the simulation of paralysis and numerous other maladies; and in the other, in anomalous paroxysms, in which globus, grimaces, and panting respiration are mixed up with tonic and clonic spasms. You may also see, in Ward 21, R. D., in whom hysteria is mingled with profound melancholia. It is not our present purpose, however, to examine into the hysterical complications of insanity, but only into one well marked type of madness, to which the name of hysterical mania has been correctly assigned.

[To be continued.]

#### LATENT TYPHOID FEVER: ULCERATION: PERITONITIS: DEATH.

JOHN WITTON, aged 16, labourer, was quite well until from ten days to a fortnight before I saw him, when he was seized with slight shivering, headache, and pains about his body generally. He felt no desire for food, but “took what came”, and continued working until February 26th, but, finding he got no better, came home; and two days afterwards I was sent for to see him. He had not suffered from diarrhoea during this time. I saw him on the afternoon of March 1st, and found him lying on his back. His countenance was anxious and expressive of pain; the skin warm, not sweating or unusually hot; pulse 112, feeble; tongue moist, furred on the dorsum in the centre. The abdomen was not much distended, tympanitic, and very tender on pressure. The bowels had acted the day before. I ordered him calomel and opium, and turpentine stupes to be kept constantly applied. When I saw him on March 2nd, he was in a state of collapse; his extremities were cold and clammy; there was great distress of countenance; the abdomen was very much distended and tympanitic; pulse 120, small and feeble. There was no appearance of any spots. He died at 6 P.M.

NECROPSY, twenty hours after death, made by Dr. Batt and myself. —Quite recent lymph covered the peritoneal surface of the bowels. A perforated ulcer was found in the ileum. Peyer's patches generally were inflamed and congested; and ulcers in various stages were found upwards to the end of the jejunum and downwards as far as the ileo-cæcal valve. Several lumbrici were found in the intestines. The body otherwise was healthy.

I am quite at a loss in this case to account for the lad having typhoid fever at all, as the house in which he lived was situated on the side of a high hill, and quite apart from any other dwelling. The water-supply is from a clear stream rising in the hills at some distance from the house, and so situated that it could not possibly be contaminated with sewage in any way. The germs of fever are, however, present; for, about a fortnight after the death of this patient, another lad living in the same house came to me complaining of all the premonitory symptoms, since which he has gone through a severe attack of the disease. I have no doubt that the lad whose case I have given would have been (humanly speaking) alive now, had he laid up at the commencement of his illness. This case shows well the fact that there is no necessary connexion between the intensity of the general symptoms of the disease and the extent of the intestinal mischief going on or the absolute danger of the case.

WILLIAM G. KEMP, L.R.C.P.Lond.  
Wellington, New Zealand, May 8th, 1871.

## THE HASTINGS PRIZE ESSAY,

1870.

ON DIGITALIS: ITS MODE OF ACTION  
AND ITS USE.\*

By J. MILNER FOTHERGILL, M.D.,

Late Senior Resident Medical Officer to the Public Dispensary, Leeds.

**Shock.**—In temporary conditions of paralysis of the sympathetic, agents which act as stimulators to this nerve are of great importance. Thus in shock, which Romberg calls paralysis of the sympathetic, the use of these agents is beneficial. Whatever may be the mode of action of external impressions, physical or psychological, that produce shock, whether in altering the molecular condition of the nerve-cells, or some other subtle action, certain it is that we have a small feeble pulse, coldness of the skin, cold breath, diminished temperature, and other evidences of the organic system of nerves being acutely depressed. In this condition, the heart-walls contract ineffectively, and do not respond to the stimulus of their contents; there is failure of the heart's action—a species of paresis. In this condition, general stimulants act well; but the question of special stimulants to the sympathetic ganglia has scarcely ever been broached. In one case of shock following parturition with twins (a common cause of shock), where there was the utmost danger of the patient's sinking, and the pulse was feeble, fluttering, and almost imperceptible, the administration of digitalis was followed by the most satisfactory results. It may be perhaps better to give the experience of some one else on so intricate a subject. Thus, in a case under Dr. Wilks (reported in the *Medical Times and Gazette*, January 16th, 1864), the patient was literally restored to life under its use. She was apparently in *articulo mortis*, her limbs were cold, her body in a state of deathly clammy sweat; the face was livid, no pulse could be felt at the wrist, and a mere fluttering was heard when the ear was placed over the region of the heart. Brandy and ether had been given without any good effect; and, as dissolution was every moment expected, it was determined to try digitalis. Half-drachm doses of the tincture were given every hour; after four doses a reaction took place, and after seven doses complete recovery occurred. The lividity of the face showed that the blood was lying in the venous system, and that it was not absent altogether. In this condition of shock, there is every reason to believe that the condition is one of passing paralysis, and that the condition of the heart is one of distension. Were digitalis a cardiac sedative, death in the two above related cases should have inevitably occurred. From the question of cardiac inability and unquestioned asthenia, we pass on to the condition of palpitation.

**Palpitation.**—Palpitation is more nearly allied to asthenia than we are in the habit of commonly thinking. Taught to regard it as over-action, we have come to associate it with excess of power; yet nothing can be more fallacious. Palpitation is a laborious evident effort, and reveals that the heart is over-taxed. It is over-taxation, not over-action with which palpitation is associated. We know perfectly well how palpitation is evoked by exertion in persons with structurally altered hearts. Here we know well that it is an accompaniment of effort; but the so-called nervous palpitation has been a troublesome stumbling block. Violent action of the heart, with a small and reduced pulse, suggested a tumultuous contradictory action of the muscular fasciculi as the only explanation of the condition admissible in the then existing state of knowledge. A condition of augmented cardiac action with no effect upon the radial pulse, was an anomaly, until advancing knowledge let us into the secret of vaso-motor alteration of the calibre of arteries. Then we began to see light shining through the darkness. Direct experiment then showed how augmented action of the heart followed certain irritation of the medulla oblongata when all nerve-communication with the heart was severed. (See Carpenter's *Human Physiology*, 7th Edition, p. 269.) It was found that alteration in the calibre of the arteries, by offering opposition to the flow of blood, caused laborious action of the heart, *i.e.*, palpitation. This action of the heart was not apparent in the arteries, because occasioned by a condition of them, which neutralised the effect of the increased action of the heart; or, more

correctly speaking, the heart's action was called out to neutralise the condition of the arteries. Thus without muscular effort, which necessitates augmented action of the heart, perceptible in the radial pulse, an evident laborious stroke of the heart may be evoked by a spasmodically contracted condition of the arteries and arterioles. Thus we have palpitation very common among the sufferers from chronic Bright's disease, in whom structural changes in the heart are most common. The diseased condition, according to Dr. George Johnson, is a thickened muscular tunic of the arterioles. The arterioles, by contraction, oppose the entrance of the blood, altered by excessive quantity of the products of retrograde tissue-metamorphosis. This contracted condition, when long continued, generates hypertrophy of the muscular tunic, and chronic opposition to the flow of blood, and then leads to changes in the heart-walls. Thus a species of balance is struck between the arterioles and the heart; cardiac compensatory hypertrophy endowing the sufferer with power to move and act; dilatation admitting a crippled existence only. Any unusual accumulation of the products of histolysis then evokes palpitation. That is, excess of the irritant provokes contraction of the hypertrophous muscular tunic, and that in its turn affects the heart; accumulating demands on it evoke laborious effort or palpitation, and this, too, more in the dilated than in simply hypertrophied conditions of the heart. Palpitation occurs commonly in such people, along with other evidences of an uræmic condition of the blood. So, also, in the palpitation of jaundice, the arterioles, by contraction, oppose the entrance of the poisoned blood, and, by the obstruction thus offered, evoke palpitation. Further acquaintance with the finer processes of pathology are doing much to enlighten us as to cardiac (so-called) functional disorders. But it is the effort at compensation which is apparent, not the disordered condition, which is the real cause. Thus hypertrophy, the evidence of constant call on the heart, was at first thought the disease; now we know that it is a reparative proceeding. Palpitation, the evidence of over-taxation, will soon be relegated to its proper position as a symptom, not as a disease. A proper knowledge of palpitation can alone tell us what agents are likely to relieve it. It is evident, then, that the means of relieving palpitation will be found in the rank of agents, which increase the ventricular contraction. It is obvious that the obstruction of a constricted aortic orifice is analogous in its action to the contracted condition of the arteries. The agents which relieve one condition must act in the other. Thus the agents which have empirically been found to exercise the strongest influence over palpitation are found to be drugs—as digitalis, belladonna, caffeine, and others—which physiological experiment demonstrates to possess the power of increasing the ventricular contraction, and which clinical observation has shewn to be of service in other conditions of cardiac asthenia. Palpitation is intimately connected with ventricular engorgement, and the means of relief are only to be found in the list of agents which augment ventricular contraction. The strangling the heart's efforts by a direct sedative like prussic acid, or allaying them by a narcotic like morphia, does not militate against this view; the one is a lowering of all vitality till the heart is equal to its work, or the general lethargy produced by a narcotic; and so the most complete cessation of palpitation could be procurable by death. The means of relief of palpitation, which leave the general system unaffected, are those which enable the heart to act more efficiently; and of these, digitalis is the chief. The whole question of temporary failure of the heart's action is scarcely yet even *sub judice*. The subject is only a promising one, and one of the deepest interest and importance; but sufficient is known to be most encouraging, and only those, who have dived deepest into the recesses of therapeutics, can estimate the amount of good which may result from the prosecution of the inquiry. The conclusions given above are not supposed to be complete; but such as they are, they have appeared to me as the result of careful thought and investigation. Better results have certainly followed, and that, too, with a greater certainty since the foregoing conclusions have shaped themselves; and in venturing to recommend them to the notice of others, the writer must deprecate any idea of a wish to proselytise. The questions are questions of fact, not questions of opinion; and though to some readers the conclusions may appear somewhat startling, they are given in all good faith; and with a strong trust that trial will be favourable, and not unfavourable, and that therefore it is to be courted. The conclusions are laid open to the verdict of the profession with all humility. It would be vain, as it would be unprofitable, to hope that the conclusions will be wholly or universally accepted. But if personal success in treatment is to be a valid test, the writer could appeal triumphantly to his experience. But it is not to record the fortunate cases here that these conclusions are fairly stated, but in the hope that, by attracting attention to this wide but little explored field of therapeutics, future benefit to sufferers may accrue.

**Contraindications.**—It is necessary to review the circumstances which may modify our views as to the desirability of administering or with-

\* Continued from page 92 of last number.

holding digitalis. We have seen that it acts by producing contraction of the heart, and, to some extent, contraction of the capillaries (or arterioles and venules). It is obvious, then, that an increased arterial tension resulting therefrom will test the integrity of the structures intermediate—namely, the arteries. It is, then, of primary importance to ascertain and bear in mind the condition of the arterial system, and to conduct our treatment accordingly. Thus, atheroma or endoarteritis is commonly associated with cardiac complaints; and more especially with those manifestations of over-taxation for which the patient consults us. The primary consequence of atheroma is hypertrophy, which sooner or later yields to fatty degeneration, in the manner described in an early section. This exceedingly complicated condition is frequently presented to us, and increases the difficulty of adopting a treatment which secures the maximum of good, and the minimum of risk. Thus, whilst the increased action of the heart (the hypertrophy) supplements the inelastic condition of the arteries, and restores the balance of the circulation, it is in itself not without an alloy, for the atheroma is most marked at those points where there is the greatest pressure; and thus the increased action tests these weak points most severely. Thus in the thin-walled vessels at the base of the encephalon, we have often rupture. So in our treatment of cardiac debility with or without hypertrophy, we must be guarded and watch the effect of our remedies most narrowly. In the palpitation of hypertrophy, this is especially necessary. It is, however, possible with care to get at what is desired without any imminent risk, but small doses alone are admissible; and until the practitioner has familiarised himself with all the complex relations of this condition, and can wield his remedy with skill and confidence, it may be safer to resort to some other agent. It is within the limits of possibility to reach the honey and yet avoid the sting, but the attempt must only be made after careful calculations as to the force of the pulse, the state of the vessels, the amount of palpitation or irregularity, and a critical weighing of the different factors. The presence of atheroma to any extent is the contraindication *par excellence* against the use of digitalis. In considering the conditions which contraindicate the use of digitalis, it is necessary to investigate the importance of fatty degeneration of the heart itself. Brunton has, from a consideration of the increased capillary opposition, warned us against its use in fatty degeneration; his objection is, however, only a theoretical one, though unquestionably rational. Reith and Gull have also made a similar objection, but on other grounds. It may, then, not be out of place here to investigate the subject critically. Firstly, the increased action of the muscular walls resulting from its use has always more than counterbalanced any capillary opposition; and the possibility of death resulting from the enfeebled heart being unable to act against the opposition so offered, may be questioned; it is only where the coronary arteries alone are the subject of disease that this could occur. In the usual condition of general atheroma, the contractility of the arterioles would also be impaired, and not respond to the stimulus of the drug. But of more serious moment is the question of partial or localised degeneration—that is, where some portion of the ventricles are more degenerate than others. This is beyond our diagnostic powers, and is therefore a purely speculative consideration. There is no question about the existence of this condition, which apparently depends on the greater or lesser amount of disease in the walls of the small nutrient arteries. It is obvious, then, that if we act on the muscular fibre remaining at all strongly, we must increase the pressure on the non-contractile degenerate portions. If we increase the centripetal action of certain portions of a hollow globe on fluid contents, we must increase the centrifugal pressure on the non-contracting portions. Thus if we produce an increased opposition to the flow of blood, and stimulate only certain portions of the ventricle, we must endanger the degenerate portions, *i.e.*, we must increase the risk of rupture through the thinned and degenerate portions of the wall. Thus the treatment may become a nice calculation of probabilities, guided by the lessons of the deathhouse. We must remember that there are numerous cases of cardiac atheria for one of rupture through a degenerate portion of the ventricular wall; and that, as physicians, we have to obviate the tendency to death. It is being of no use to allow the patient to die of atheria, from a hypothetical risk of rupturing a rotten section of the heart-wall. The probabilities must guide us. The variation between the sounder and more diseased parts can rarely be so great as to make this a practical danger. The difficulty of acting on the walls at all reduces even the possibility of the risk. This condition, too, is usually associated with advanced disease of the arteries; and thus we have the practical danger of rupturing them to estimate, as well as the hypothetical one of increased centripetal action of one acting section of a hollow sphere increasing the centrifugal pressure of the fluid contents on the non-acting sections.

As well as these contraindications which present themselves as pathological conditions modifying our views as to the desirability of ad-

ministering digitalis, there are others which present themselves as connected with the diagnostic indications, as, for instance, intermittency. The occurrence of intermittency during the administration of this agent has hitherto been deemed a valid contraindication; and certainly if we feel assured that it is the consequence of the drug, it is an evidence of its physiological effects being reached. Thus, if along with it we find the pulse becoming thready, the heart's action becoming a steady thud, a diminution in the bulk of urine, showing a lessened pressure on the glomeruli of the kidney, then it may be necessary to withdraw the digitalis. It may, however, not only be no contraindication to its use, but even be the strongest evidence of the need for its administration in increased quantity. Thus, where any obstacle is presented at all suddenly to the circulation, and digitalis is given, intermittency may come on as the result of the heart's inability, in spite of the stimulus to contraction to struggle against it; and the administration of the agent in increased quantity may be clearly indicated. This is no imaginary condition. Some months ago, the writer attended an old gentleman of ninety, suffering from an acute affection of the aortic orifice, accompanied by dropsy, orthopnea, and feeble pulse. Digitalis was given by him as usual; and after a day or two the pulse commenced to intermit, and there was evident increasing circulatory debility. It was with great difficulty the scruples of the consulting surgeon could be overcome, and his permission gained to give the digitalis in double doses. After that, the pulse improved; the intermittency took its departure; the dropsy declined; the old gentleman could again lie down, after sitting in an arm-chair three weeks without intermission; the digitalis was continued, and the old gentleman was once more walking about in his garden. Thus we see that intermittency and the other evidences of cardiac debility coming on during the administration of digitalis may not only not be contraindications against its use, but may even be the strongest evidence in favour of the administration of it in increased quantities. The diagnosis as to whether the intermittency be due to the drug, or to the necessities of the patient being aggravated, would rest to a great extent on the conditions under which the drug was given. Thus, if it were given to allay the palpitation in hypertrophy, and in a healthy person, there would exist an *a priori* probability that it was due to the action of the drug; if digitalis were administered in great cardiac debility and growing obstruction, or obvious failure of the heart's action, the occurrence of intermittency may be the evidence of an imperative necessity for an increase in the dose. The occurrence of persistent vomiting, loss of appetite, noises in the head with flashes of light, or other symptoms of the system being fully under the action of the drug, or of some idiosyncrasy on the part of the patient, would suggest to us instinctively its withdrawal; and either the use of some similar agent, or its administration in some other form or combination. Thus patients who soon show an intolerance of digitalis if given on an empty stomach before food, tolerate it if given an hour or so after meals. The occurrence of attacks of syncope or other cardiac failure cannot be said to be any valid objection to its use; in fact, like intermittency, they may indicate the necessity for more of it. In some persons it is desirable certainly to give it along with diffusible stimulants. But failure of the heart under its use will be found to be the result of the affection, not the drug. Thus persons with fatty or otherwise degenerate hearts, where it is given, are subject to the attacks as the result of their ailments. "Such patients are liable to die suddenly, and will do so now and then whether digitalis be given or not." (Gull and Wilks, *Medical Times and Gazette*, July 1865.)

*Antidotes.*—Though digitalis-poisoning is no longer so common since a more accurate knowledge of its action has lent precision to its administration and its use, still cases might occur where, through misadventure or oversight, or perhaps some peculiar susceptibility in the patient, a condition of danger might arise from its administration. Such a condition must carefully be distinguished from attacks of cardiac syncope, the result of disease. If it were once ascertained that the danger was due to the drug, it would be necessary at once to stop its use; if it resulted from one huge dose producing acute poisoning, it might be advantageous to empty the stomach; in chronic poisoning, sickness is spontaneous. The use of agents must be resorted to which are known to paralyse the heart—for instance, aconite. In experiment on the frog, though aconite did act on the heart after the poisonous effects of digitalis had been induced, still its action was far from being so marked as when digitalis was given in aconite-poisoning. In digitalis-poisoning, aconite may be resorted to as an antidote. From the action of the Calabar bean, as described by Dr. T. R. Fraser, of Edinburgh, it is highly probable that it would act beneficially in the excessive action of digitalis. From the consideration of antidotes, it may not be out of place to consider the question of agents of similar action.

[To be continued.]

## CHLOROFORM ACCIDENTS.

By JOSEPH LISTER, F.R.S.,

Professor of Clinical Surgery in the University of Edinburgh.

MR. CLOVER, in an article in the *JOURNAL* of July 15th, opposes the views expressed in my essay on *Anæsthetics in Holmes' System of Surgery*. The esteem which all who know Mr. Clover must entertain for his personal character, and his large experience in the administration of chloroform, attach a weight to his observations which compels me, though with great reluctance, to trouble your readers with some remarks in reply.

The main difference between us may be shortly stated as follows. I recommend a folded towel as at once the simplest and safest means of administering chloroform, and I hold that when this is used the respiration becomes obstructed before the circulation fails, and that circumstances occasionally arise in which the patient's life will be placed in imminent jeopardy unless the obstruction be cleared away by firm traction upon the tongue; and further that, as this interference with the breathing may occur in a very insidious manner, it is wisest for the administrator to keep his attention riveted upon the respiration rather than have it distracted by simultaneous observation of the pulse. Mr. Clover, on the other hand, regards the folded towel as a dangerous means of administration in comparison with an apparatus of his own devising, which has proved so successful in his hands that, while he has given chloroform more than seven thousand times, he has never lost a single patient, nor has he ever seen it needful to draw forward the tongue except in so far as that is done by raising the chin. But he thinks it necessary to observe the pulse, and he believes that if he had neglected it, his practice would not have been free from fatal event.

These statements of his are undoubtedly very striking, and can hardly fail to produce an impression upon your readers; but while in some respects highly instructive, they are also, I believe, calculated to mislead. When Mr. Clover tells us that out of more than seven thousand cases he has not lost one, I can but rejoice, not only because this is in itself a great and glorious fact, but because it tends strongly to confirm the proposition which I have sought to enforce; viz., that, though cases of death under chloroform must now and then occur, with which the anæsthetic has nothing to do, and though I am not prepared to deny the possibility of an idiosyncrasy of excessive rarity, and of which I have never yet seen an instance, that may make death from chloroform inevitable, yet in the main, fatal results really due to the agency of this narcotic are preventable. But when Mr. Clover attributes his great success to a special apparatus, and when, by proclaiming his own example, he practically counsels medical men in general to disregard the drawing forward of the tongue, he makes, as I believe, a great mistake, and with the best intentions, promulgates most mischievous doctrine.

With regard to the safety of the folded towel, my personal experience affords sufficient evidence. I estimate the cases in which I have been concerned in the administration of chloroform as about 3,500, and though this number is only half Mr. Clover's, the practice to which it relates is really of much greater value than his with reference to the point under discussion. In his cases, the undivided attention of the most experienced special chloroformist in the country was bestowed upon the administration. In mine, the chloroform was, as a general rule, not given by myself at all, but by young men coming fresh to the duty every three months, and whose only instructions were to watch the breathing closely, and, in case of its obstruction, remove the cloth from the face, and at once adopt means to clear away the obstacle. That under such circumstances my practice should have hitherto remained free from fatal accident is far greater evidence of the safety of the cloth than Mr. Clover's can afford respecting his apparatus. It is idle to speak of the folded towel as dangerous when it has stood a test like this.

I now come to the drawing forward of the tongue. Here Mr. Clover leaves me to choose between two horns of a dilemma. The fact that I resort to traction upon the tongue while he does not, proves, he says, either that my method of administration is at fault, or else that I resort to a needless procedure. Neither of these alternatives, however, necessarily follows. Mr. Clover, in contrasting my practice with his own in this respect, compares two things not fairly comparable, for the reasons above given. If I devoted my exclusive attention to the administration of the chloroform, I should, for aught I know to the contrary, draw the tongue forward as seldom as he. The necessity for the procedure undoubtedly implies in the great majority of cases that rather more chloroform has been given than necessary, though happily, as experience shows, not more than is safe. Accordingly we commonly see it

resorted to especially at the beginning of a session when the junior officers to whom the duty of giving the anæsthetic is entrusted are fresh at the work; and Mr. Clover is wrong in supposing that traction upon the tongue is of very frequent occurrence in our practice. I am not sure that it has been done once during the last two months, although we have had about as many operations as days. But it is of the utmost importance that students should learn the art of chloroform administration, and we regard the opportunity which they have at our Scotch schools of being instructed in this art as one of their most valuable privileges. With such beginners and with the large number of practitioners throughout the country who, unless the benefits of chloroform are to be most needlessly and lamentably restricted, must be called upon to give it without much experience, the necessity for traction upon the tongue will from time to time occur. And I have seen enough to make me perfectly sure that lives will be needlessly sacrificed if it be not resorted to. When, therefore, Mr. Clover virtually recommends medical men generally to follow him in abstaining from this practice, he gives about as pernicious a piece of advice as can well be given with reference to the administration of chloroform.

Mr. Clover gives a new theory of the obstruction to respiration under chloroform. He regards it as an act of deglutition imperfectly performed. Swallowing, he tells us, is often excited by chloroform, and "there is reason to think that the co-ordination of the movements which constitute deglutition is interfered with," so that the act "lingers in the second stage." Surely this is a mistake from beginning to end. Is there any reason to think that the act of swallowing is thus disturbed by chloroform? On the contrary, it continues to be performed in patients deeply under the influence of the anæsthetic, so that not only are the saliva and buccal mucus prevented from accumulating in the pharynx, but blood flowing into the mouth, unless the hæmorrhage be free, is safely carried down into the stomach. Were it otherwise, we should have to refuse chloroform in many cases in which we now employ it. Nor is it true that chloroform "excites swallowing." So far, at least, as I am able to judge, what it does excite is a free flow of saliva, and the secretion is either got rid of by swallowing, or, if the patient be an adult male, accustomed to another sialogogue, tobacco, he causes inconvenience to the attendants by ejecting the liquid in the manner usual with smokers. It would be as rational to say that chloroform excites spitting, as that it excites swallowing. That the obstruction to the breathing has nothing whatever to do with deglutition is plain enough from other considerations. In my article on anæsthetics, the obstruction to the respiration under chloroform is shown to be of two totally distinct kinds, one of which is removed by drawing forward the chin or turning the head to one side; while the other refuses to yield to such treatment. The former obviously depends on relaxation of the lingual muscles. I lately had occasion to remove a tumour affecting the central part of the lower jaw, dividing, of course, the attachments of the muscles by which the tongue is protruded; and the condition of the patient during the first few days after the operation reminded me exactly of the state of a person with the tongue relaxed by chloroform. He was threatened with suffocation if he lay back with the occiput towards the pillow, but breathed freely when the face was turned well to one side, or when the tongue was drawn forward in the gentlest manner by a string attached to it. An experiment that may be made on any patient affected with this variety of obstruction from chloroform is of itself conclusive. Supposing the obstacle to have been removed by the gentle traction on the tongue, effected through the medium of its muscles by pulling forward the maxilla by the beard, it will at once return if the chin is allowed to recede, and the same thing will recur time after time as often as you please. To imagine that a fresh act of semi-deglutition takes place every time you relax your hold would be absurd.

The same argument applies to the other kind of obstruction to the breathing under chloroform. This requires firm traction upon the tongue to dispel it, and it recurs whenever the traction is suspended in a manner obviously unconnected with any act of deglutition. Mr. Clover, indeed, seems never to have witnessed this variety. But before expressing an opinion upon the nature of "the obstruction Mr. Lister dwells upon," he was surely bound to read the account I gave of it. If he will turn to either the article in the first edition of *Holmes's Surgery* or its present revised form, he will find it stated that "I have more than once seen a person holding the end of the organ considerably beyond the lips without any good effect, and, placing my hand on his, have given an additional pull that has re-established the respiration." It was this observation that first attracted my attention to the subject. It struck me as something very remarkable that when the tongue was already carried to the extreme degree of extension, additional traction, though it did not alter the position of the organ, should clear away the obstruction. This seemed quite irreconcilable with the prevalent idea that mere falling back of the tongue was the only thing at fault, and I

felt anxious to know more of the true nature of the phenomenon. I found that I could imitate in my own person the profound stertor which commonly precedes and passes into the obstruction in a patient under chloroform, and that I could still produce it when my tongue was protruded beyond the range of the teeth; but that if I seized its tip with a handkerchief and pulled it forward sufficiently strongly to cause a painful sensation in the frænum lingue, the snoring became impossible. The effects of drawing forward the tongue being thus exactly the same upon the artificial stertor as upon that under chloroform, I could not doubt that the two were identical, so that I had the opportunity for further investigation in my own throat. By digital examination I ascertained that the epiglottis was not folded back in this stertor as it is in swallowing, but that the seat of the vibrations was more deeply placed, somewhere about the orifice of the larynx. I next made an attempt to see its exact mechanism in an animal under chloroform. The experiment was performed upon a sheep in a slaughter-house in Glasgow; and though it was abruptly cut short by the advent of an official who threatened to haul me up before the Provost and magistrates if I persisted in such cruelty to animals, I saw enough to interest me greatly. The animal having been brought deeply under the influence of the anæsthetic, I made a free transverse incision in the throat so as to enable me to look fairly down upon the orifice of the larynx. But, to my surprise, instead of seeing the vocal cords, I saw only a pair of vascular valves flapping with great rapidity, and concealing entirely the true vocal apparatus. I then availed myself of the laryngoscope for further observation in my own person, and at once ascertained what the valves I had seen in the sheep really were, viz., the thick, pulpy, vascular folds of mucous membrane surmounting the apices of the arytenoid cartilages; and I saw that if I coughed, these folds were brought into contact in the middle line, and, at the same time, were carried forwards to the base of the epiglottis, so as to obstruct the exit of air till the expiratory effort had continued sufficiently long to produce a due outburst, when the obstruction was removed. Thus the strain in coughing is not allowed to fall upon the delicate mechanism of the vocal cords, but is borne by these valves of mucous membrane. When anything irritating is present in the air inhaled, these valves guard the inlet to the larynx and render it as small as possible, as I had seen in the sheep during the inhalation of chloroform; and they constitute the mechanism of what I have termed true laryngeal stertor. On producing this stertor while examining my throat with the laryngoscope, I saw these pulpy folds vibrating at the base of the epiglottis; and on increasing the stertor to complete obstruction, I observed them closely applied and motionless. Then, on drawing forward the tip of my tongue with one hand, while the other held the laryngoscopic mirror, as soon as the traction was carried so far as to become painful to the frænum lingue, while the epiglottis was not moved forward in the slightest degree, the arytenoid folds receded from its base in spite of the effort of my will to the contrary, rendering the obstruction and the stertor alike impossible. Thus the view to which I had been previously led became established, viz., that the firm traction on the tongue operates not mechanically, but in a reflex manner through the nervous system. And this conclusion has since received confirmation from a remarkable case (to which I have drawn attention in the revised article) where, the chest continuing to heave, the obstruction to the respiration remained in spite of firm traction on the tongue, but yielded at once to a dash of cold water, which could only operate through the nerves.

I cannot but regard these facts as of vital interest to the administrator of chloroform; and my apology for bringing them at such length before your readers must be that, though they are duly recorded in the article which Mr. Clover criticises, he does not appear to have noticed them, but confuses together the lingual and laryngeal obstruction in his very crude theory of imperfect deglutition.

Long as this communication already is, I must crave your indulgence while I add some remarks on Mr. Clover's statements regarding the influence of chloroform on the circulation. He is "convinced that the chief cause of danger is the effect of chloroform upon the heart;" and he alludes to fatal cases which have been reported by others where the pulse is said to have failed before the breathing; and he also mentions some experience of his own tending in the same direction. On Mr. Clover's own observations in this respect, I place implicit reliance; and to these I shall have occasion to refer again. But I confess to feeling little confidence, as a general rule, in the reports of deaths under chloroform. I know from experience how insidiously the laryngeal obstruction may supervene, and how readily the heaving of the chest under such circumstances may be mistaken for efficient respiration; and I have described in detail in my revised article, a case illustrating very strikingly how a fatal event commencing with asphyxia might be mistaken for a death from the heart. (See *Holmes's Surgery*, 2nd Edition, vol. 5, p. 497.) I know, also, how conflicting the evidence of bystanders com-

monly is with regard to the precise succession of the highly important events that are crowded together in the brief period of excitement immediately preceding the patient's dissolution; and we know, further, the strong tendency that exists in the mind of any one in whose hands such a case has occurred to twist the evidence unconsciously to himself in favour of inevitable syncope, rather than preventable asphyxia; and when we bear in mind how liable the attention of the administrator is to be distracted by the interesting circumstances of the operation, to suppose, as some appear to do who write upon this subject, that no such thing as death from chloroform through negligence ever occurs, and that all the whitewashings of coroners' inquests are strictly accurate, is to carry charity far beyond the bounds of probability. It must also be borne in mind that death must sometimes occur under chloroform as a pure coincidence; and, indeed, it is remarkable how many cases of this sort have been substantiated by indisputable evidence (*Vide op. cit.*, p. 484). In one or other of these ways, I believe the great majority of alleged instances of death from chloroform by syncope may be accounted for.

But to return to Mr. Clover. He remarks that, "supposing the larynx to be obstructed at a time when the heart is acting well, and when not more than four or five per cent. of chloroform-vapour is in the chest, the narcotism will diminish" through diffusion of the chloroform among the tissues. But he forgets that meanwhile the narcotism from asphyxia will be rapidly increasing and that asphyxia, together with a full dose of chloroform is an exceedingly formidable combination. That my dread of it is no groundless apprehension, is sufficiently proved by the case lately referred to, as detailed in my revised article. In that instance, the breathing being obstructed, but the chest still heaving, the face passed through the condition of asphyxial lividity into what was physiologically identical with *post mortem* pallor; and although the heart had not yet failed, it was obvious that death was imminent, when traction upon the tongue happily restored the patient to life. But I cannot believe it to be really needful to convince Mr. Clover that asphyxia under chloroform is dangerous. His own practice of raising the chin, which he has "never known to fail" in relieving the obstructed breathing, seems sufficient evidence that he is in reality quite alive to the risk.

Mr. Clover proceeds to contrast what is observed when a patient holds his breath while inhaling air containing only four per cent. of chloroform, with what would be likely to occur if the proportion of the narcotic vapour were as high as ten or twelve per cent. I am compelled to enter an earnest protest against the idea here conveyed, that anything approaching such high percentage is likely to occur when a folded towel is used. To suppose such a thing is not only to make a purely gratuitous assumption, but to ignore entirely a very careful set of experiments which I made several years ago and published in the article referred to (*vide op. cit.*, p. 486), in order to ascertain the amount of chloroform really given off by the towel. The circumstances which led me to enter upon those experiments were not very dissimilar from those which have now arisen. Dr. Snow had ascertained, by observations upon the lower animals, that in chloroform-poisoning, if more than about five per cent. of the vapour existed in the air, the creature died from primary failure of the heart; but, if the percentage were kept below that figure, the respiration failed before the circulation. And with respect to the latter fact I beg leave to refresh Mr. Clover's memory. Having come to this conclusion, Dr. Snow invented an inhaler, as Mr. Clover has done, to regulate the proportion of chloroform to the atmosphere; and, finding it answer well on a very extensive trial, and forgetting, like Mr. Clover, how largely his success might be dependent on care in the administration, he jumped to the conclusion that fatal events in the hands of others were due to primary failure of the heart, in consequence of too large a proportion of chloroform assumed to be present when the folded towel was employed. Meanwhile the folded towel had long been used in Edinburgh with a success even greater than that attained by Dr. Snow; and, when anything indicated an overdose, it was not failure of the heart, but an obstructed state of the respiration. How was this inconsistency to be explained? Were Dr. Snow's experiments fallacious? or was he wrong in assuming that the cloth involved a risk of too great percentage of chloroform? In the hope of clearing up this difficulty, I resorted to experiments; and, carefully avoiding all apparent sources of fallacy, I ascertained that, if a drachm and a half of chloroform were used, the whole amount given off by the under-surface of the cloth at the temperature of 70 deg. F. during the first half-minute after the liquid was poured upon it, was only such as to produce a percentage of 4.5 to the air inhaled by an average adult, supposing all to enter the lungs. But in reality a considerable quantity is not inhaled at all, part of the heavy vapour falling down beside the patient's face, and part being blown away by every act of expiration. It would be difficult to estimate the

precise amount of this loss; but that it must be very great is evident from another consideration to which I directed attention—viz., the safety with which chloroform is given to infants by means of the towel, without any precaution to adapt the quantity of liquid used to the small capacity of their lungs. If anything near the whole of the chloroform that comes off were inhaled by children, its proportion would be enormously high and necessarily deadly. Their immunity from danger proves, therefore, the greatness of the waste of the anæsthetic.

From these facts it seems probable that, even when the chloroform has just been poured upon the towel, the amount actually inhaled does not exceed that which Mr. Clover uses as a constant quantity throughout the administration. And, considering how rapidly the rate of evaporation from the cloth diminishes, it is manifest that the average quantity taken into the lungs when this method is employed is very greatly below that supplied by Mr. Clover's apparatus. Mr. Clover may perhaps reply that this is impossible, seeing that patients cough more with the towel than with his apparatus, implying that what they breathe is more pungent, and therefore stronger. But greater pungency of the inhaled air does not necessarily imply a larger proportion of the irritating material. Any one who has watched the clear blue Rhone flowing side by side with the milky Arve, far below their place of confluence near Geneva, will readily understand this. When the chloroform has just been poured on the middle of the cloth, its vapour falls in very large proportion from the moistened part upon the mouth and nose; but from the sides of the towel, and from beneath its edges, pure air rushes in simultaneously, and the two fluids pass imperfectly mixed into the fauces and trachea. On the other hand, the atmospheric gases and the chloroform are perfectly blended in Mr. Clover's balloon; and just as a glass of spirits and water well stirred tastes milder than the same ingredients unmingled, so the gases inhaled from Mr. Clover's apparatus appear more bland, though in truth more potent, than the unmixed gases beneath the towel.

I have been accustomed to regard Mr. Clover's apparatus as in his hands a harmless luxury; but when I find him at the outset of his article denying broadly that in deaths from chloroform the respiration is affected before the circulation, and when he relates in illustration a case "out of many which tend to show that the pulse must be watched", where during tranquil inhalation the pulse gradually failed and became imperceptible while the breathing continued free, though this also afterwards ceased, in spite of discontinuance of the inhalation, so that the patient seemed for a while really dead, I am led to doubt whether experience so entirely contrary to ours with the towel may not be due to the larger proportion of chloroform given. These statements of Mr. Clover make me more than ever satisfied that the cloth, though a rough and ready and somewhat wasteful means of administering chloroform, is the safest of any yet devised.

But even if Mr. Clover should reduce his percentage of chloroform, so as to ensure primary failure of the respiration rather than of the heart, it would not follow that his apparatus would be a desirable thing for general adoption. Its only advantage is the avoidance of irritation of the air-passages by the pungent vapour; and this, after all, is but a trifling inconvenience, and patients seldom complain of it. On the other hand, not only are Mr. Clover's bag and mouthpiece a cumbrous means of effecting the object, but, though perfectly safe in his hands, they might not always prove so in those of others. I lately heard of a case in which this apparatus being employed, and the patient showing no signs of being influenced by the anæsthetic, it was found on investigation that the introduction of chloroform into the balloon had been omitted. Now, it is certainly full as likely to happen that too large a supply might be introduced through ignorance or hurry, in which case a more efficient means of quietly destroying human life could hardly be devised. For an agent adapted, like chloroform, for universal employment by medical men, it is of the utmost importance that the means of administering it should be as simple and uncomplicated as possible.

Before concluding, it may not be deemed out of place for me to advert shortly to Mr. Syme's experience with chloroform, more especially as my practice is simply that which I learnt from him. Though I may hope that I have done something to elucidate its theory, I have added nothing to it. It remains as it was at the outset, except that, instead of the tongue being drawn forward on every occurrence of obstruction to the breathing, it has of late years been found that the slight puncture inflicted by the artery-forceps may often be avoided by the means before referred to. With Mr. Syme, from first to last, a cloth on which the chloroform was freely poured was the only means employed. The breathing was taken as the only guide, while no inquiries were made into the state of the heart; and the administration was conducted by junior officials of the hospital. Yet in a surgical career which has been estimated as involving the giving of chloroform

upwards of seven thousand five hundred times, he did not meet with a single death from the anæsthetic.

I venture to hope that this discussion, though I fear it has been on my side carried to a tedious length, may tend to increase the confidence of the profession in this safe and simple practice. Should this prove to be the case, I shall not have abused the patience of the reader.

## INTESTINAL OBSTRUCTION FROM A KNOT ON THE LOWER PART OF THE ILEUM.\*

By MICHAEL W. TAYLOR, M.D., Penrith.

MRS. S., aged 40, the wife of a small farmer, was a full-sized, finely made, robust woman; she had been the mother of several healthy children, the youngest of whom, aged fifteen months, she had suckled until quite recently. She had led an active and regular life, and possessed all the attributes, and indeed had been in the enjoyment, of perfect health, and had never been subject to more than the most trivial derangement of the bowels. On Thursday, November 17th, 1870, whilst engaged in baking, on lifting a heavy pan from the ground, she was sensible of having strained herself on the left side of the abdomen, but the pain passed off directly and she ceased to regard it. Another circumstance which ought to be mentioned in this place as a possible cause of the intestinal entanglement, the results of which were soon to be developed, was, that on this evening at supper, and also on the following morning, she feasted very freely on boiled cockles, which to her were a very unusual kind of regalement. I have no evidence to show whether the slight "overreach" or this indigestible meal was the cause of her illness; but on the evening of Friday she was seized with a cramp and twisting pain in the abdomen, recurring acutely for a time, and abating for intervals of twenty or thirty minutes. During the night she vomited frequently: what was rejected was not food that had been taken, but a yellow bitter fluid, having the colour and appearance of bile. A dose of castor-oil which was given to her was speedily vomited.

She was first visited in the forenoon of Saturday, November 19th. Her expression wore an anxious appearance, as of a person suffering from abdominal distress. The gripping pain was referred chiefly to the epigastrium; it was intermittent, and there were periods of tolerable ease; at other times she turned from side to side, as if suffering severely. There was but little tenderness or distension over any part of the abdomen—indeed, pressure somewhat relieved her. There was no increase of temperature, nor of rapidity of pulse beyond 80. The tongue was coated white. The last motion which passed from her bowels was on Wednesday. There was no abdominal protrusion, nor abdominal enlargement, nor thickening to be felt in any situation. On viewing the case at this period, the symptoms accorded with the presumption that the attack might turn out merely as one of colic, from the irritation of indigestible matter, and might pass off with the removal of the offending cause. To effect this, blue pill and colocynth were given, with alkaline and sedative draughts; and frequent hot linseed-meal poultices were ordered. These pills and a portion of the medicine were retained, and it seemed that during the remainder of the day she felt herself easier and thought herself better, although no evacuation from the bowels had been procured. The night, however, was one of great suffering, from the frequent and violent recurrences of the pain and vomiting, so that a summons came to visit her at five on the morning of Sunday, the 20th. The matter vomited was green bilious fluid; it was rejected from the stomach with considerable force. The pain was still referred to the epigastrium, over which she acknowledged a slight amount of tenderness, from which, however, the rest of the abdomen was free, although it was now becoming slightly rounded in contour and tympanitic on percussion. An enema of one pint of warm water and eight ounces of olive oil was injected, which had the effect of relieving the lower bowel of a considerable quantity of fecal matter in the form of scybala and pellets, but not of a loose nor fluid motion. Two pills, with a quarter of a grain of morphia in each, were left for administration every two hours. Shortly afterwards she obtained ease; she was able to take a little beef-tea; the paroxysms of pain and sickness ceased, and she obtained some sleep. On visiting her in the evening, the pain in the epigastrium, though not so severe, had become more constant, and more aggravated by pressure; there was more general distress and restlessness, and great thirst, dry skin, dry tongue; pulse 64, hard. She had vomited recently, from time to time, a quantity amounting to a washhand-basin full of brownish-yellow fluid, with a distinct fecal odour. There had been no further evacuation from

\* Read before the Cumberland and Westmorland Branch, May 3rd.

the bowels. It became certain now, that physical occlusion existed in the intestinal tract. The question of the first importance was to define the site and locality of the obstruction; and, in the second place, from among the multiform and diversified, and sometimes anomalous, pathological causes of ileus, to differentiate to which the present symptoms might be more precisely referred. The parietes of the abdomen seemed to contain a considerable thickness of muscle and fat, but not to such a degree as to depreciate the results of an exploratory examination by palpation and percussion. There were no coil-like markings over the abdomen; the bulging there was to a moderate extent only; the regions presenting the fulness were the epigastrium, the umbilical, and the hypogastrium: the percussion resonance over this superficies was drum-like and amphoric. There was no fulness nor distension of the sides above the *crista ili*, in the localities occupied by the ascending and descending colon, nor was there dulness over these spaces—the signs which generally supervene in strictures at the sigmoid flexure. Viewing these indications, and moreover the fact that this morning the injection had penetrated a portion of the colon and cleared it of its contents, there was already ground for the presumption that the obstruction was not in the large intestine, but at some point at or above the cæcum.

To consolidate the diagnosis thus far, and also as a remedial measure of the first importance, it was determined to use O'Beirne's long tube. A flexible tube was passed up carefully into the colon to the extent of twenty-two inches, and the presence of its extremity in the neighbourhood of the transverse arch was rendered unequivocal by auscultating the passage of the injection as it flowed at that spot. A pint of linseed-oil suspended in a quart of warm milk was thrown in. The injection flowed readily; it caused pain, and it was discharged in a few minutes without having contracted any fecal odour, or having any fecal admixture of any consequence.

When it became apparent that this aid, often so useful, but useful chiefly in cases of impaction in the larger bowel, had failed, I resolved to try a method which in two desperate cases of ileus I have used with immediate and unmistakable success; viz., the inflation of air charged with the vapour of chloroform.

The method by insufflation is as old as Hippocrates; for, after antiphlogistic and emollient measures and clysters had no effect, he then ordered "wind to be thrown into the belly by a pair of smith's bellows, that both the abdomen and cramped muscles might be distended, and then, withdrawing the bellows, a clyster to be injected—not prepared of things very warm or heating, but of such as dissolve or mollify the feces; then the patient was to sit on a perforated chair over a sponge of hot water charged with the ingredients of a clyster". Alexander of Tralles, or Trallian, as he came to be called, in treating of the cure of the present malady, gives us the following express caution and sound advice regarding inflation. "If it be a cold colic, or an iliac affection without any preceding inflammation, in that case it might be of use to practise the cure by inflation; but if the bowels are locked up by an inflammation antecedent, the method of cure by inflation will be not only useless but even prejudicial."

The method by which I cause the air to be charged with chloroform is by an apparatus fixed between the hand-bellows and the flexible rectum-tube, consisting of a circular wooden-box containing a sponge; the box is pierced with an aperture fitted with a plug or screw, through which the chloroform may be dropped when required. The air, on being forced through the sponge by the bellows, becomes highly charged with the chloroform-vapour. This method was used in the present case; air and chloroform-vapour were blown into the bowels for some minutes slowly and gradually, until great distension, apparently of the whole abdomen, was produced. It was attended, however, with no immediate benefit nor satisfactory result; no stool nor flatus were passed. As she seemed much exhausted and faint from the pain of the procedure, nothing further was then attempted. A pill with half a grain of opium and a quarter of a grain of belladonna was ordered every three hours, to be alternated with small doses of sulphate of magnesia and sulphuric acid and tincture of belladonna.

On the morning of the 23rd, it was found that she had passed a better night, and had slept for two or three hours at a time. There had been no vomiting, and but little tormina. She had not been sensible of the violence of the air injected on the previous day, nor of any movement or rumbling in the bowels. In the course of the day, however, the attacks of tension returned, and the urine discharged, with a jerky action of the stomach, several mouthfuls of greenish-yellow fluid without fecal colour; there were some hiccoughs and shivers; pulse 86. The long tube was again introduced, and an injection of six ounces of milk, in which ten minims of tritichinal were suspended, was thrown into the colon. This had the effect of setting up energetic peristaltic action of the bowels; in half-an-hour the injection was returned, but without fecal

admixture, though still with a fecal smell; a vast quantity of flatus also came away, but without characteristic odour. She stated that for the first time she now felt a stir and rumbling in her bowels, whereas hitherto all had been fast and torpid, noiseless and without movement. At this stage a hope was entertained, from the slightly more favourable indications presented by a return of peristaltic action, that some passage might be effected. So far there had been an absence of the general or local symptoms of inflammation either of the peritoneum or of the bowel itself. The case was judged to be one of simple ileus, with distension and paralysis of the muscular coat of the bowel, without inflammation, as described by Abercrombie; and it was certain from the results of the exploratory injections that the site of the mischief was above the cæcum.

Early on the morning of the 22nd, the retchings, which had abated after the enema, returned. There had been several attempts, but no evacuation. The abdomen was not altogether free from pain, and there was a very slight amount of tenderness; pulse quiet. An enema of warm water and a dose of two ounces of spirit of turpentine was administered; shortly afterwards the injection was returned, mixed with a small quantity of fecal matter. The whole surface of the abdomen was kneaded with oil, and emollient poultices were applied, and pills with compound tincture of colocynth and one minim of croton oil given.

In the evening it was found that the purgative pills had been speedily vomited; the nausea and retching were more aggravated; hiccough frequent; no stool. She stated that she recognised the taste of turpentine distinctly in the fluid rejected from the stomach to-day; and the discharges which had been preserved certainly gave out the smell of turpentine, showing apparently that some of the injection had ascended to and penetrated the constriction, and mingled with the retained intestinal contents above—a fact most noteworthy, as showing that the occlusion was not thorough nor complete. The abdomen was rubbed with equal parts of belladonna and glycerine. The pills of opium and belladonna, which had been taken up to this time, were stopped, as they were frequently rejected, and their physiological effects was not discerned.

November 23rd. The vomiting and hiccough continued, but with longer intervals; beef-tea and effervescing drinks having been sometimes retained for two or three hours. There had been great thirst; pulse 86. Half an ounce of spirit of turpentine was given by mouth, and an enema containing the same was administered, and stupes of turpentine were applied to the abdomen. The turpentine draught was retained for three or four hours, and she passed several times a quantity of flatus. Urine had all along been passed in large quantity, containing abundance of urates. She was ordered to continue the turpentine applications.

November 24th. She passed an uneasy night, with no sleep. She vomited twice during the night a quantity of yellowish green fluid; pulse 104. There was no increase of tension nor of pain in the abdomen. An ounce of castor-oil was given and retained. *Vespere*: There had been no more retching; she continued to pass wind in small quantity; pulse 98; tongue red and dry. A large injection of oil and soap and water was given; on its return it brought away a large quantity of wind, after which she expressed herself much relieved.

November 25th. About 3 A.M. an attack of vomiting occurred, which brought up the castor-oil which had been swallowed fourteen hours before. At 7 A.M., having felt a desire to go to stool, she rose up, unaided, and passed flatus with great force, and with a strong fecal odour, and also a small quantity of thin fluid of a fecal nature; she passed at the same time a quantity of urine. At 9 A.M., stercoraceous vomiting occurred, and again at 12 noon. She broke out in a profuse clammy perspiration, and expressed herself as being relieved afterwards. The pulse was more frequent, 104, weak and constricted.

November 26th. Occasional retchings occurred during the night, without fecal admixture. There was no passage from the bowels; the general condition was much the same. One-twelfth of a grain of strychnia and a quarter of a grain of belladonna was ordered to be given every three hours. The abdomen was rubbed and kneaded with camphorated oil.

November 27th. There was no material change; four pills had been taken. She stated that, after having swallowed any food or fluid, she felt an impulse downwards to the lower part of the bowels, where the action stopped and became inverted, and was by and bye followed by vomiting.

As is often the case in this malady, we had arrived at a point in the treatment at which we were brought completely to a stand, at which it was in vain to affect the repetition of measures which had failed, and when it was becoming evident that it was too late to cast about for fresh principles of treatment. It had so happened that this morning, on the persuasion of a friend, she had been induced to take a large quantity of

fresh brewer's yeast—the intention of which remedy I suppose to have been that it might evolve in the bowels a quantity of fixed air, and so extricate any unnatural twist or convulsion that might have been formed. She was desired to continue it along with treacle-beer.

November 28th. There had been no vomiting since yesterday. There had been sensations of movement and peristaltic action in the bowels, and offensive flatus had been passed repeatedly. She had felt more relieved and easier than for several days, and she was even hopeful. This result she attributed to the yeast which she had taken. It was a delusion, however, created probably by that mental perverseness, not unusual, which is apt to bias sense in favour of nostrums and advice derived from unorthodox or spurious sources, for in material respects no improvement could be substantiated—indeed, on the 29th, fecal vomiting had recommenced, with much hiccough and general anxiety and distress. The abdomen had become decidedly tympanitic and painful on pressure; pulse more frequent, very feeble and compressible. Enemata of beef-tea were ordered every three hours.

November 30th. Fæcal vomiting occurred; she had hiccough, eructations, great prostration; the exposed parts were cold and clammy; she was nearly pulseless; the tongue was red, and there were sordes about the gums; the mental condition was drowsy and semi-stupid. Diffusible stimuli were ordered.

December 1st. Death took place at 3 A.M. She had passed nothing from the bowels, and had vomited fecal matter to the last. The mind was conscious. The duration of the disease was fourteen days.

*Necropsy Eight Hours after Death.*—The body was plump, with a considerable layer of fat in the parietes of the abdomen, which was greatly distended, and had a drum-like resonance. The peritoneal covering was smooth and glistening, and disclosed no inflammatory appearances nor products. The small intestines were much distended, and concealed from view all other organs; their parietes were thin and transparent, without rupture, and not remarkably changed in colour, until approaching the right iliac region, where a livid mass of strangulated bowel indicated the site of the obstruction. The lower portion of ileum along with the cæcum was removed for examination; and the cast now exhibited was taken from the preparation. A portion of the ileum, about

a. Ileum. b. Cæcum. c. Distended loop of Ileum. d. Knot.

twenty-two inches in length, was found tied in a running knot about two inches above the cæcum. The entanglement must have taken place in this wise: about twelve or fifteen inches of the lowest part of the ileum must have become coiled in a circular loop; the portion of the intestine directly above must have twined round from behind to the front of this coil; a knuckle or rather elbow of this portion of the bowel must then have accidentally slipped through the loop, and, having become embraced by it, on the tightening of the noose, have been caught in a slip-knot, or the same knot as that by which sailors hang their neck-tie. This included portion formed a sort of *cul-de-sac*, being bulged out into a globose form, with a semilunar outline, like a bag or pouch, measuring five inches by three, and marked on the surface with the depressions of six or eight sacculi or folds. It was drawn into puckers at the neck, but the little finger could be passed freely under the point of constriction; it contained fluid, and was not immoderately distended, and the colour was heightened only and not livid. It was the cæcal or distal end of the ileum which constituted the knot, which was in one place of a dark brick-dust or brown colour, and in another coil of a livid purple, and in parts black, soft, and gangrenous. This was the point at which the constriction was greatest. Below the knot the distension and dark colour terminated abruptly. The cæcum and colon were white and collapsed. The stomach was empty; the gall-bladder full. No disease was found elsewhere.

REMARKS.—It is the disclosure of the pathological cause that attaches to this case of ileus an interest and importance; and the value of it depends on the circumstance, that it affords a perfect example of an exceeding rare form of intestinal lesion—viz., true knotting of the bowel. Amongst the various causes of intestinal obstruction seated in the bowel itself, as distinguished from those which proceed from constrictive agencies external to the intestine, we may arrange under the one head of volvulus, two subdivisions—viz., (a) twists or folds of the intestine on its own axis; and (b) twists around another piece of bowel, or knots. Volvulus, even strictly in its generic sense, as including both these two forms of entanglement, is a comparatively unfrequent cause of ileus; and species b, or knotting of the bowel, is a lesion of the extreme degree of rarity. Dr. Hilton Fagge (*Guy's Hospital Reports*, 1868) has given the records of all the cases of intestinal obstruction which have occurred at Guy's Hospital for fifteen years, from 1854 to 1868 inclusive. The necropsies were fifty-four in number; and only seven died from twists or folds of the intestine, or volvuli; and I do not find one case amongst them from knotting of the bowels. The most elaborate essay on intestinal obstruction is that of Duchaussoy, published in 1860 (*Mem. de l'Académie de Médecine*, 1860, xxiv). It is founded on the results of five hundred and eighteen observations, in which the anatomical changes are accurately described. Out of these five hundred and eighteen fatal cases of ileus, twenty-one were caused by "strangulation of the intestine by the intestine", and are tabulated by him under head No. 2, under which he includes various forms of displacement and compression, as well as twists and volvuli. On examination of the causes of the strangulation in these twenty-one cases, as set forth by Duchaussoy, I find that thirteen were caused by twisting of the bowel on its own axis in various ways; that four were from *enroulement*, or from a piece of bowel being wrapped or rolled around another; and amongst these only one case of the bowel being knotted. The case is reported from Parker, and the facts are given in a note. Like the case just related, the entanglement was formed on the lower ileum, near the cæcum, by two loops, one passing within the other, and drawn tight into a knot an inch and a half long. In one of the loops was a cherry-stone. The case was operated on by enterotomy. The knot could not be unravelled, but was cut off. The case recovered in four and a half months.

I have examined the volumes of our British medical periodicals for half a century. They furnish many reports of cases of ileus, the more numerous being cases of intussusception. Cases arising from twisting of the bowel, are related by Abercrombie, Oudney, and one or two others; but I have found no reference to any case of knotting of the bowel.

I have no remark to make about the diagnosis, as there are no means by which to distinguish this from some of the other forms of internal strangulation.

A consideration of the condition of the parts, as shown by the cast, will make it manifest that no medical remedies could have been of service; and that the only available chance, would have been enterotomy and untwisting and reducing the loop by the hand, which would have been feasible in this instance.

## EXCISION OF THE ELBOW-JOINT: PRESERVATION OF EXTENSION OF THE FOREARM.

By C. F. MAUNDER, Esq.,  
Surgeon to the London Hospital.

Of the major operations, probably no one is more successful in saving life and securing a useful limb than excision of the elbow-joint. The articulation is reached, and the ends of the bones are exposed and removed with comparative ease, by a posterior longitudinal incision, with or without the addition of a short transverse cut—the latter through the skin only. By complying with the general principles of surgery applicable to resections, few important structures are injured by the knife, and as a result we have a most useful limb—one, it is said, generally capable of performing to a large extent *all* the functions and movements of the healthy member.

It is from this latter statement that I venture to differ. Flexion shall be good, supination and pronation tolerably good; but *extension* of the forearm is generally impossible. For the latter defect, the mode of operating is responsible; but the remedy is easy, and our knowledge of anatomy will supply it. Although probably the majority of surgeons now employ the longitudinal incision, yet a certain structure to be alluded to is often severed to facilitate the operation, because its value is unknown. It is possible that the reader will be surprised when I say that the power of extension is rarely preserved; and when

it is, the means is probably not understood. On testing the movements retained by the forearm of a patient who has undergone excision of the elbow, extension appears perfect, while in reality it may be, and often is, altogether absent. A patient is desired to bend and then to straighten the forearm. He complies with the former request; but, when the limb becomes again straight, it is purely by the force of gravity: the hand and forearm fall, but are in no way extended by the triceps. The triceps muscle has no longer an attachment to the forearm. It will be remembered that the triceps muscle, while being firmly attached to the olecranon, also sends some of its tendinous fibres beyond that process to blend with the fascia of the forearm, especially with that portion of the fascia overlying the anconeus muscle; and by these fibres it is that extension may be *always* insured after excision. It is, however, probable that in exceptional instances the cut triceps acquires attachment to the end of the ulna, through the medium of fibrous tissue formed during repair. By this means, some amount of extension is secured; but it is accidental, and cannot be foretold in an individual case.

**Operation.**—In speaking of this operation, I must be understood to refer to that method by which the articular ends of the bones are cut away to the extent to which they are normally covered by cartilage—the one now generally adopted. I commence by a longitudinal incision at the back of the limb, in length three or four fingers' breadth both above and below and crossing the point of the olecranon. Then, if there be a wound in the adjacent integument, conveniently situated, I generally lay it open into the longitudinal incision, and am able to expose the bone-ends with greater facility. I next let the knife sink into the triceps muscle, and divide it also longitudinally into two portions, the inner one of which is the more firmly attached to the ulna, while the outer portion is continuous with the anconeus muscle, and sends some tendinous fibres to blend with the fascia of the forearm. It is these latter fibres that are to be scrupulously preserved. Thus, in conducting the early steps of the operation, two chief points have to be

remembered, instead of one (care for the ulnar nerve) as hitherto advised. The ulnar nerve, often unseen, must be lifted from its bed, and be carried over the internal condyle to a safe place; and then the outer portion of the triceps muscle, with its tendinous prolongation, the fascia of the forearm and the anconeus muscle, must be dissected up, as it were, in one piece, sufficiently to allow of its being temporarily carried out over the external condyle of the humerus. This done, the operator may proceed in the usual way; but it is not my intention to follow him further in this paper. I will add, that I have exhibited at meetings of the Humeral and Medical Society of London three patients, adult males, who had undergone excision of the elbow-joint; and all who saw them were surprised by the degree of active extension of the forearm by the triceps muscle which each possessed.

The drawing shows the state of parts after primary excision has been performed, by the usual longitudinal incision, upon a left extremity. The tenaculum sustains the band of fibres, which is to be preserved uncut.

## CLINICAL MEMORANDA.

### HERPES ZOSTER, GIVING RISE TO CONTAGIOUS (?) ERYSIPELAS.

AFTER reading Dr. Broadbent's interesting case of herpes frontalis giving rise to contagious erysipelas, which appeared in the *JOURNAL* of July 22nd, I am induced to refer to the following case, at present under my care.

A man aged 63, an out-patient in the Hulme Dispensary, suffered on June 27th from severe pain extending round the trunk on the right side. There were no abnormal physical signs, and no swelling nor redness of the skin. Temperature 98.4 deg. F. On July 4th, there was a well marked belt, composed of groups of herpetic vesicles, distributed over the whole of the right side of the thorax between the fifth and ninth ribs. These groups were perfectly defined, and appeared in several successive crops. On July 8th, erysipelatous inflammation of the affected side had appeared, which speedily spread so as to invade the left side also. At this stage, the swelling and redness were so marked and of such a diffuse character, that it would have been difficult for one seeing the patient for the first time to say what was the true nature of the case. By the 13th, these symptoms had nearly disappeared, leaving characteristic light brown scabs, some of which have now become detached, exposing small scars or pits, indicating that it was a true case of zoster, followed by erysipelas. The treatment consisted of saline purgatives, followed by thirty-minim doses of tincture of perchloride of iron, to which was afterwards added five minims of liquor arsenicalis, three times a day.

A son of my patient, who had been on a visit to his father, and had slept with him for some nights, was said to have returned home with a "red rash on his skin" exactly like his father's, which disappeared at the end of five days without medical aid. Viewed in the light of Dr. Broadbent's case, it is not improbable that it may have been an erysipelatous attack, communicated by the father to the son; but, be that as it may, it is interesting to note the occurrence of herpes zoster, a neurotic affection, with erysipelas, apparently in the relation of cause and effect.

C. CURRIE RITCHIE, M.D.,  
Physician to the Hulme Dispensary, Manchester.

### REMOVAL OF THE PITTING OF SMALL-POX BY ERYSIPELAS.

DURING the time that I held the post of Medical Inspector to the Privy Council, I saw at Chesterfield an elderly woman who told me that in her youth she had suffered severely from small-pox, and that for several years she had been disfigured by the pitting which resulted from it; but that, after a sharp attack of erysipelas, accompanied by much swelling of the face, the pitting had disappeared, with the exception of a few spots between the eyebrows. When one's attention was drawn to the woman's face, one could see that she had had small-pox by the few remaining marks just mentioned; but otherwise there was no indication of it, for her skin was smooth, and in an excellent condition for a person at her time of life. Have any similar cases been observed?

ALFRED WILTSHIRE, M.D., M.R.C.P.,  
Physician for Diseases of Women to the West London Hospital.

**ROYAL COLLEGE OF SURGEONS.**—At the examinations for the diploma of membership which were commenced on Friday last, and brought to a close this day (Friday), 114 candidates offered themselves. Of these, 43 had previously obtained a recognised medical diploma; 54 were examined in medicine by the College examiners; and the remainder preferred obtaining licenses in medicine elsewhere.

**TREATMENT OF DIVIDED TENDONS.**—In the case of a young man who had received a wound from a billhook on the back of his hand, dividing the extensor tendon of the middle finger, Dr. Bessières had two splints made, curved on the flat: one, the palmar splint, was large enough for the hand; while the dorsal one was two finger-breadths wide. The wound was united by a suture passing through the skin only; the concave surface of the palmar splint was then applied to the hand, and the convex surface of the dorsal splint to the middle finger which was kept thus (with the aid of diachylon plaster) in a state of extension. At the end of three weeks, a little stiffness in flexion remained; and six weeks after the injury the man had complete use of his finger.—*Annales de la Société Méd.-Chir. de Liège*; and *Journal de Méd. et de Chir. Pratiques*, Février 1871.

### MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS OF GREAT BRITAIN.

#### NOTES ON THE TREATMENT OF GANGLION IN THE DUBLIN HOSPITALS.

##### RICHMOND HOSPITAL.

The following is a *résumé* of Dr. R. ADAMS' treatment.

The most simple form of ganglion, and that which is most frequently met with, appears in the shape of a small fluctuating tumour on the back of the wrist and carpus. This he always treats by passing through and through the tumour a curved surgical needle, at the same time pressing forcibly with both thumbs the swelling, so as to expel completely the glairy contents of the tumour through the two orifices made by the traversing needle. Thus the opposed surfaces of the interior of the ganglion are made perfectly to confront each other: but this is not enough; a small compress must be immediately placed over the space which had been occupied by the ganglion, and the hand and fore-arm of the patient is to be placed on a support, such as that which Burton's American hand-splint forms, and should be retained there for at least fourteen days. There is a fluctuating bursal swelling (classed by some under the head of ganglion) formed sometimes in the bursæ of the tendons of the flexor muscles of the fingers, and which is remarkable for presenting a prominence not only in the palm of the hand below the annular ligament of the wrist, but also an oblong prominence above the narrowing of the wrist in the site of the annular ligament. This species of bursal swelling (denominated by the French *en bissac*) appears to Dr. Adams to be, on the one hand, very amenable to antiphlogistic treatment and rest; on the other hand, he has known active surgical treatment, consisting in punctures and incisions made into such bursal tumours, productive of very sad results. He has, for example, a distinct recollection of three cases of this form of bursal tumour, which to his knowledge had been treated by incisions into the bursal swellings, and in these three cases it became necessary to amputate the fore-arm above the elbow-joint. Dr. Adams informs us that, in the forthcoming second edition of his treatise on *Chronic Rheumatic Arthritis*, he will find it necessary to produce an engraving of the hand and fore-arm of a patient (see woodcut) in whom an oblong swelling

had formed in the bursæ of the tendons of the flexor muscles of the fingers; and in this case the bursal swelling was treated actively by an incision made above the annular ligament. Acute inflammation, attended with what Baron Dupuytren denominated "internal strangulation" and gangrene, supervened, and amputation became necessary.

Mr. JOHN HAMILTON believes that, when the ganglion on the back of the wrist is of medium size, with thin walls, it is best treated by the common proceeding of breaking it with a smart blow with the flat of a book, while the wrist is kept at the utmost degree of flexion, making the parts tense. The neglect of the latter proceeding often causes failure. When the sac is ruptured and the contents effused into the surrounding cellular tissue, the application of a compress, formed of a piece of money or sheet-lead, wrapt in lint, and kept on for a few days, usually ensures a perfect cure. If it fail, or that it cannot be broken, he has succeeded in this way: he draws the skin aside, and passes a narrow tenotomy-knife into the sac, endeavouring to make the wound in the sac irregular and lacerated by knocking with the edge of knife in different directions, to prevent its union. A compress, as in the previous method, is then applied. He thinks the ganglion is more liable to a

return after this plan of treatment than after breaking it. Another, and Mr. Hamilton believes a preferable plan, is shown in the following case. Miss B., aged 12, had a ganglion of the size of a chestnut on the back of the right hand near the wrist, over the carpal end of the metacarpal bone of the index finger, freely fluctuating, and the integument moving over it readily. But, though it could be moved from side to side, it evidently was connected with the extensor tendons. It had been blistered; pressure had been perseveringly applied; and an attempt made to break it with a book. This last he tried, but unsuccessfully. He therefore punctured it with Weiss's grooved needle, and a perfectly limpid fluid, of the consistence of white of egg, but purer-looking, came out, till about one-third of the contents had escaped, when, from the smallness of the opening, it ceased to flow. The integuments, which had been pulled aside, were then let fall back into their place, and covered the opening. The hand was put on a splint, and a compress of sheet-lead and lint firmly applied. This was kept on, with occasional removals, for a month. It was then removed, after which, though at first there was a little fulness at the part, it entirely disappeared, and never returned. Mr. Hamilton does not like the seton; it is very hard to limit the amount of inflammation caused by it. He prefers to open the ganglion freely, and insert a piece of lint into the cavity. This excites inflammation and suppuration, and effects a radical cure. The suppuration gets free vent; and on this account the irritation is less than where matter is formed in the sac from the irritation of a seton. When there are foreign bodies in the ganglion, either like melon-seeds or irregular-shaped bodies of cartilaginous texture, pain, absent in the ordinary ganglion, is usually felt. He makes a free valvular opening, through which the foreign bodies are extracted. This proceeding has always been followed by inflammation of a troublesome character. Mr. Hamilton thinks that we should not forget that ganglions cannot always be opened without some apprehension, and that the general health should be carefully considered before anything of the kind should be done. Monro and Sir B. Brodie both relate cases of death from this cause. Sir Philip Crampton had mentioned to him a similar case. Mr. Hamilton had seen an instance where such violent inflammation and suppuration followed opening the ganglion in the front of the wrist beneath the annular ligament, that finally amputation above the elbow had to be performed.

##### JERVIS STREET HOSPITAL.

Dr. AUSTIN MELDON finds ganglion one of the most common affections in the dispensary of Jervis Street Hospital. The following mode of treatment he seldom finds to fail. If the cyst do not yield to firm pressure, a tenotomy-knife is introduced subcutaneously. This is made to travel through to the opposite wall of the cyst. This latter is scarified freely, and the knife withdrawn. A small piece of thick paste-board or the like, about the size of a halfpenny, is next placed over the ganglion and fixed by means of several pieces of sticking-plaster, arranged as in cases of anthrax. This is left on for twenty-four hours and then restraped, and generally in the course of a short time all sign of the affection has disappeared.

##### STEEVENS'S HOSPITAL.

Mr. W. COLLES and Dr. R. McDONNELL think that the treatment of ganglion varies considerably with the exact nature of the case; but their experience has led them to form a favourable opinion of evacuating the contents and injecting tincture of iodine. This they find on the whole a satisfactory mode of treatment.

The treatment which Dr. HAMILTON usually adopts for ganglion consists in rupturing the cyst either by the steady pressure of both thumbs or by sudden percussion, so as to discharge the contents into the surrounding areolar tissue, and to promote by firm pressure the adhesion of the walls, so as to obliterate the sac; this may be effected by a compress of cork, hemispherical in shape, and adapted in size to each case. It should be covered with chamois leather and firmly secured by a bandage, so as to bring the walls of the cyst into as close and accurate contact as possible. In cases where the cyst is too thick and strong to resist this mode of evacuation, it would also more than probably resist the after-treatment by simple pressure. Dr. Hamilton then adopts the following method of dealing with the disease. A hypodermic syringe, charged with tincture of iodine, is introduced into the cyst and intrusted to the care of an assistant at the opposite side; a grooved needle is inserted, and the contents evacuated along the groove. The needle is now withdrawn, and pressure made for a few seconds on the puncture; the tincture of iodine is then discharged from the syringe into the sac; moderate pressure is made with a compress and bandage. He had not seen inflammation reach a troublesome degree, although the pain is in some cases severe.

##### ADELAIDE HOSPITAL.

Dr. BARTON's experience is that, when a ganglion is situated upon

the back of the wrist, and when it is small and circumscribed, the old treatment of rupturing the sac by a smart blow, and then putting on pad and bandages, does very well; but when it is situated on the anterior aspect of the limb—particularly when occurring, as it generally does, in weakly young persons, then this treatment is not satisfactory. A case occurred to Dr. Barton some years ago, in which the ganglion was on the back of the wrist, rather large, and not distinctly circumscribed. It had been ineffectually struck before he saw it. He was obliged in this case to pass a silver wire through the sac, and in a few days sufficient inflammation was set up to obliterate it. Another case he treated a few months ago—a weakly girl of fourteen. It was on the front of the wrist. He struck it first without hurting it; and, seeing he would have to use too much force in this way of treating it, Dr. Barton punctured it with a grooved needle. He cleared out the contents and put on pad and bandage; but it gathered again, and he was obliged to pass a silk thread through the sac. When the contents became turbid and the tumour swollen and tender, he withdrew the ligature, and it was permanently cured.

Mr. B. WILLS RICHARDSON, when the cyst is tough, and when practicable, opens it subcutaneously with a fine tenotomy-knife, so as to discharge the contents into the surrounding areolar tissue; he then scratches or scores the inside of the cyst-wall, and, having withdrawn the knife, applies a firm pad (such as a penny-piece covered with chamois leather) over the collapsed cyst, and secures it in position with a roller. Some ganglion-walls are so thin, that they may be ruptured by firm pressure made with the thumbs. When ganglia have been in situations to render the knife unadvisable, Mr. Richardson has treated them successfully by bursting them with a book. A few years ago he saw a tolerably large ganglion under the ball of the thumb and greater part of the palm of the hand. It was ruptured with a book. Firm pressure was made over the broken sac for some time, and it did not refill. Should the surgeon be inclined to inject the ganglion, say with tincture of iodine, he must first endeavour to ascertain if it communicate with a joint. A ganglion that opened into a joint has been injected before now, and the joint destroyed. If, before operating, it be necessary to discover whether an ordinary ganglion communicates with a joint, this is much more imperative as regards some of the synovial cysts near large joints. This, however, cannot be always ascertained; for in some cases the contents of the cyst are so thick, and the communication between the cyst and the joint so narrow, that it is impossible to squeeze the semifluid contents from the sac into the joint.

### ROYAL INFIRMARY, ABERDEEN.

#### DEATH OF A PATIENT WHILE UNDER THE INFLUENCE OF CHLOROFORM.

(Under the care of Dr. PIRRIE.)

Dr. PIRRIE has kindly forwarded the notes of this interesting case for publication.

Peter Urquhart, aged 37, a moderately stout man, but said to have been of intemperate habits, was brought into the theatre of the Aberdeen Royal Infirmary, at twelve o'clock on Wednesday, the 19th of July, for the purpose of having Wood's operation for the radical cure of hernia performed on him. Chloroform having been administered by one of the clinical clerks, in the presence of Dr. Kerr, Dr. Fiddes, and myself, the means employed being a single fold of a towel held over the face, I had just made the preliminary incision, and was in the act of performing denudation of a small portion of skin from the sub-jacent parts, when my attention was called, by one of my colleagues, to the alarming appearance of the patient, whose pulse and breathing had suddenly ceased. His trunk, head, and neck were immediately rendered straight; his tongue drawn out; artificial respiration, by Sybister's method, commenced and vigorously carried on; ammonia was applied to his nostrils; galvanism energetically used; water dashed on his face and chest; and a vein at the bend of the arm and the external jugular vein opened: from the latter a small quantity of blood flowed. The treatment was continued for half-an-hour, but without any return of the signs of life. It may be mentioned that, though the patient was exceedingly anxious for an operation, he was greatly alarmed at the prospect of it, and expressed a decided wish that chloroform should be administered.

**Post Mortem Appearance.**—The examination took place on Friday, July 21st, and was conducted by Dr. Beveridge in the presence of Dr. Gibson, Professor of Medical Jurisprudence, Dr. Kerr, Dr. Fiddes, and myself, when the following appearances were observed.

Externally, there were diffuse lividities of the surface over the sides of the face and neck, fronts of both shoulders, outside of the arms, inside of the thighs, and the dependent parts of the head, trunk, and lower limbs. The joints of the upper extremities were flaccid, those of

the lower rigid; the pupils were pretty widely dilated; the features placid. The scalp was bloody on removal; the vessels of the pericranium minutely injected; the dura mater, at a point corresponding with the upper edge of the frontal bone over a space of about an inch in breadth, had lost its usual smooth glittering appearance, and its vessels there and generally were congested. Bloody points were perceptible here and there in the grey matter of the convolutions of the brain. The cerebral ventricles were filled with clear fluid, the right lateral one to distension. The choroid plexus was loaded with fluid blood; the cortical part of the cerebellum throughout was darker than usual, and of a marked purplish hue; the blood within the head was fluid and dark, in rather greater quantity than usual, the excess of blood chiefly confined to the sinuses. The brain weighed fifty ounces. The walls of the heart were slightly flaccid; there were three ounces of fluid blood in the right cavities of the heart, four and a half drachms in the left; blood thinner than natural and frothy. The walls of the left ventricle and the septum cordis were in an advanced state of fatty degeneration; the walls of the right ventricle appeared, to two of the examiners, to be thinner than usual. The lungs, particularly at their dependent parts, were deeply loaded with dark fluid blood, but otherwise healthy. There was partial fatty degeneration of the kidneys. The blood throughout the cavities of the body, on exposure to the air, became brighter than usual. The blood and a large portion of the liver were examined on the following day in the laboratory of the university by Professors Brazier and Ogston; but the usual process of passing the vapour from those substances through a red-hot tube did not yield any of the usual indications of the presence of chloroform.

My colleagues and myself are of opinion that death was the result of mixed causes, viz.: chloroform inhalation, dread of operation, and diseased condition of heart, the last being the most influential.

### TAUNTON AND SOMERSET HOSPITAL.\*

#### LOOSE CARTILAGES IN THE KNEE-JOINT.

(Under the care of Mr. H. J. ALFORD, M.B.)

THE following case is reported by Mr. G. W. RIGDEN, house-surgeon.

S. W., aged 39, a labourer of Somerton, was admitted into the Taunton and Somerset Hospital on April 22nd, 1871. He had noticed for some months that he could not bend his right knee so easily as his left; but, as he was able to walk about and do his work, he took but little notice of it. About three months before his admission, he first found a lump on the outer side of his right knee-joint, and had noticed that it was not always there.

On admission, it was found that there was no pain in the joint, and no effusion. Two loose cartilages were most distinctly felt at the outer and upper edge of the patella. His knee could be flexed or straightened without pain. He could bear pressure on any part of the joint, and the cartilages could be easily manipulated without causing pain. A pad of lint was fixed between the patella and the cartilages by means of a figure-of-eight bandage, in order to prevent them from slipping back into the joint; and the limb placed in a McIntyre splint.

On May 1st, Mr. Alford entered a tenotomy-knife about two inches above the cartilages, while an assistant was pressing them upwards; and, after a few sweeps of the knife, the cartilages were pushed up out of the joint into a bed prepared for them under the skin of the thigh. A strip of strapping was then firmly fixed between them and the joint, and the bandage and splint were reapplied. The patient was ordered to lie perfectly still, and to be kept on low diet for a week. No inflammation followed the operation.

On May 20th, Mr. Alford removed the cartilage by means of a simple incision. The wound was dressed with carbolic acid dressing, and the figure-of-eight bandage was firmly applied, as also the McIntyre splint.

It was not until June 8th, when the wound was quite healed, that the strapping above the joint was removed, together with the splint. A figure-of-eight bandage was applied, and the patient advised, for safety, to remain in bed a few days longer. This he did not do, and on June 10th he left the hospital.

The cartilages were found to present the appearance of ossifying cartilage. They were flattened and oval in shape. One weighed 106 grains, and the other 90 grains.

The case is interesting, not only as showing how two such large bodies can exist in the knee joint without much inconvenience, and can be removed from it, but because the disease is rare. The last case seen in the Taunton Hospital was in 1862, and was reported by my predecessor, the late Dr. Gibson, in the BRITISH MEDICAL JOURNAL for that year. In that case there was but one cartilage, weighing 160 grains; and it was removed by Mr. Alford in the same way.

\* Read before the West Somerset Branch.

## THE ANNUAL MEETING, 1871.

TICKETS OF ADMISSION are being issued to members, the presentation of which will be necessary in order to obtain the privileges granted by the Railway Companies with whom arrangements for the journey to and from Plymouth have been made. (See page 132.) Gentlemen intending to be present at the meeting, should at once send their names to Dr. Littleton, 1, Lansdowne Place, Plymouth.

## BRITISH MEDICAL JOURNAL.

SATURDAY, JULY 22ND, 1871.

## DYNAMICS OF NERVE AND MUSCLE.

## I.

AN interesting book on the *Dynamics of Nerve and Muscle*, by Dr. C. B. Radcliffe (Macmillan and Co., 1871), tempts us to make some observations on the subject, not only because the theme is one of surpassing interest, but also because Dr. Radcliffe—one of the busiest practitioners in this distracting metropolis—has for years been able to find time to labour at a subject which is one of the most recondite in the whole range of physiology. We cannot agree with all that Dr. Radcliffe says on this subject; but, although we dissent from some of his views, we would none the less cordially congratulate him on this effort, and we trust that he will continue his researches with the unflagging zeal which characterises him.

We cannot here follow Dr. Radcliffe in the discussion of all the points on which he dwells in his treatise, but we shall take up a few of the more salient. As the starting point of his doctrines regarding nerve and muscle action is to be found in his views regarding the electrical phenomena of these tissues, we shall refer first of all to this subject.

There is scarcely any portion of scientific history which has more fascination for the physicist or for the physiologist than that concerning animal electricity. A century all but a year has elapsed since Walsh, by his discovery that the shock of the torpedo is due to electricity, laid the foundation-stone regarding animal electricity. Fourteen years later (1786), Galvani made the celebrated observation which ushered in a new era in the history of electricity, and stamped his name with immortality. Most fortunate is it for us that in Galvani's household were to be found those whose delicate palates enabled them to appreciate the exquisite flavour of frog-flesh. But for this, the rancid legs, all ready for the cook, might never have lain in Galvani's kitchen, and would, therefore, in all probability have escaped the convulsions into which they were thrown when brought under the influence of an electric machine. When Galvani found out that frogs' limbs were so easily thrown into convulsions by electricity, he employed them as electroscopes. He found that, during a thunder-storm, they were convulsed when it lightened; but, greatly to his surprise, he, by experimenting further, observed that even in a stormless state of the sky the legs, under certain conditions, became convulsed just as if they had been affected by lightning. This discovery was made by Galvani in this manner. Having decapitated and denuded a frog, he thrust a copper hook through the spine, and suspended it to the iron trellis work on a terrace in his garden. It was a fine September evening; the sky was stormless; but, notwithstanding this, when the evening breeze caused the frog's legs to dangle against the iron bars, the legs, greatly to Galvani's astonishment, were thrown into contractions the moment they touched the iron. Dismissing the idea that the electricity which thus convulsed them could be in the atmosphere, he, after finding that the legs were convulsed whenever he connected the muscles to their nerves by an arc of copper and iron, concluded that the electricity which caused the twitchings was produced in the tissues themselves. The excitement that Galvani's discovery produced was intense. Our invaluable friends the frogs were nearly exterminated by the terrible massacre which was made in

order to satisfy the scientific world of the truth of Galvani's discovery. The vulgar fancied, as indeed it is to be feared the quacks get them to fancy nowadays, that "Electricity is Life", and so they believed that all ailments might be cured by simply putting electricity into the body. Volta, however, soon put a spoke in the wheel of the Galvanists. He was professor of physics in Bologna at the time when his colleague Galvani was dazzling the world. He found that he failed to get Galvani's contractions unless he connected the muscles with heterogeneous metals such as copper and iron, and he in consequence considered these to be the source of the electricity. But Galvani found that the twitchings ensued when the nerves and muscles were connected by only one metal—*e.g.*, copper or mercury. To this Volta replied that, as it is scarcely possible to get any two parts of the same metal in precisely the same condition, there is always more or less heterogeneity, and that in consequence of this two parts of the same metal might give rise to currents just as if they had been dissimilar metals. Galvani was for a time silenced by this; but at length he found that he could get these contractions without any metals at all, by simply letting the sciatic nerve fall upon the gastrocnemius. Volta was irrepressible: he had caught the idea that heterogeneity of substance was the cause of the electricity; and so now he silenced Galvani by saying that, although he had got rid of heterogeneous metals, he had still to get rid of heterogeneous tissues. The contact of the sciatic nerve with the surface of the gastrocnemius was, after all, just the contact of heterogeneous tissues, and this contact was the source of the electricity. To crown all, Volta, proceeding from this idea of heterogeneous metals, constructed the battery which has ever since been called the Voltaic pile, and thereby gave such force to all that he had said that Galvani's views fell into total disrepute. In 1827, Nobili, by means of the galvanometer, demonstrated the existence of electricity in the frog, and thus showed that Galvani, although he was wrong in disregarding the contact of heterogeneous metals as a source of electricity, was nevertheless right in maintaining the existence of electricity in the muscles of this animal. Since Nobili's time our knowledge of the subject has been vastly extended by many workers, but more especially by Matteucci and Du Bois Reymond. According to Du Bois Reymond, *living* nerve and muscle are *continually* generating electrical currents. The longitudinal surface of the fibres is positive, while the ends of the fibres are negative. The electricity generated in the nerve or muscle is generally supposed to be of low tension—in short, it is believed to be that kind of electricity termed galvanic, voltaic, or dynamical. When muscle and nerve are thrown into action, the electrical current obtainable from them is greatly diminished. This diminution is generally regarded as indicative that less electricity passes towards the surfaces of the muscle or nerve fibres. Du Bois Reymond endeavours to explain the electrical phenomena of muscle and nerve by supposing that these tissues contain a number of minute moveable particles, each one of which has two negative poles and a positive equator. While the tissue is at rest, the negative poles point to the ends of the fibres and the positive equator to the longitudinal surfaces. During action he supposed that a partial rotation of particles takes place, whereby the positive equator of one particle is brought against the negative pole of a neighbouring particle. The electrical currents, instead of then passing towards the surfaces of the fibres, are, as it were, short circuited, and kept almost entirely within the substance of the fibre. A model constructed by Du Bois Reymond on this hypothesis serves, as we have often convinced ourselves, to demonstrate experimentally the chief electrical phenomena of muscle and nerve. Some, indeed, have smiled at Du Bois Reymond's hypothesis of these mobile peripolar particles; but the greatest living physicist—Helmholtz—regards it as one of the most valuable ideas which we owe to the distinguished Berlin physiologist.

In the opinion of Radcliffe, however, there are no *currents* in muscle or nerve, unless the longitudinal surfaces of the fibres be artificially connected with their ends. He believes that the electricity is *static*, and that, as Galvani long ago imagined, the fibres resemble Leyden jars. These living "jars" are, according to our author, charged with elec-

tricity when they are living and at rest, and when they pass into action they discharge their electricity. As the statical nature of the electricity, the state of *charge* during the inaction of the muscle and nerve, and the *discharge* of electricity during action, are fundamental points with Radcliffe, it becomes us to examine them somewhat closely. He supposes that by oxidation or some other cause positive electricity is evolved outside the sarcolemma—to speak of muscle only, for convenience—and that this by induction causes the substance within the sarcolemma to become negative. In this way the fibre resembles a Leyden jar, the glass or dielectric of which is represented by the sarcolemma. Radcliffe has constructed a model of muscle on this hypothesis, and, according to him, this model suffices to illustrate all the facts. If this be true, then, we have two schemes constructed on two very different ideas which illustrate the facts that may be observed. Were Radcliffe's view the correct one—we may say in passing—that we fail to see why it is that he will have the electric state of the sarcous substance determined by the evolution of electricity outside the sarcolemma—the converse might be just as probable, perhaps rather more so. But there are difficulties which hinder the acceptance of Radcliffe's Leyden jar hypothesis. It involves the existence of a bad conductor—a dielectric—such as the sarcolemma is supposed to be, around the substance of the fibre, which shall answer the purpose of the glass in the Leyden jar. True, in voluntary striped muscle we may say that we have this. In nerve, the white substance of Schwann, or the nerve-sheath, might be made to do service in support of the view; but in the striped muscle of the heart, and in unstriped muscle generally, where is the dielectric membrane to come from? It would, we think, be simple imagination to put a membrane round these fibres. If Radcliffe cannot show the existence of such a membrane, or of a structure that will serve instead of it, his Leyden jar view seems to us untenable. But Du Bois Reymond's view needs no such membrane. It harmonises with, so far as we know, all the facts of our case, and therefore we cannot as yet consent to lay it aside.

As is well known, when a torpedo or other electrical fish is irritated, a discharge of electricity ensues. According to Matteucci and Radcliffe, a similar discharge takes place when a muscle or a nerve is irritated: this is termed by them the "torpedo-like discharge". The existence of this discharge is absolutely essential to support Radcliffe's views regarding muscle and nerve action—indeed, he seems to us to base every thing upon it. Where is the evidence of the discharge? Two facts are adduced. 1. If we place a muscle or a nerve on the electrodes of a galvanometer, wait until the needle deflected by the current from the tissue comes to rest (at say 30 or 40 deg. from zero, in the case of a muscle), and then throw the tissue into action, we find that the needle returns towards zero, and that if the active state of the tissue be kept up the needle rests near zero, or even at it. In the case of nerve, indeed, it sometimes happens that the needle goes to the other side of zero, indicating a reversal of the poles of the nerve. This, says Du Bois Reymond, is due to a partial rotation of the peripolar particles of the tissue leading to a diminution of the electric tension at the free surfaces of the tissue, and, it may be, to a positive reversal of the poles of the tissue. On the other hand, Radcliffe maintains that the return of the needle to zero is evidence of discharge or escape of the electricity from the tissue. Unless we can in some way catch the going guest we decline to believe in his departure. 2. It was thought by Matteucci—and Radcliffe is of the same opinion—that the following experiment is evidence of the departure of the electricity in the case under discussion. If we take the legs of two frogs having the sciatic nerves dissected out, and left in connection with the gastrocnemii; let us call the one leg A and the other B. Lay the nerve of the leg A upon the gastrocnemius of the leg B, and then irritate the nerve of the leg B. Most curious it is to see that when the gastrocnemius of B contracts the gastrocnemius of A contracts too. The nerve of A is irritated by something which takes place when the muscle B contracts. What is that something? The torpedo-like discharge of electricity, say Matteucci and Radcliffe; the mere diminution of electricity at the surface of the muscle B as it passes into

the state of action, says Du Bois Reymond. According to Du Bois Reymond, when the nerve is laid on the surface of the muscle, the electricity at the surface of the latter necessarily passes into the nerve. The contraction of the muscle causes a diminution of this electricity, and in consequence of the partial or complete disappearance of the electricity, the nerve is irritated just as when a continuous current of electricity passing through the nerve causes irritation by its sudden arrest. Which view is correct? Du Bois Reymond's view explains the fact just as well as Matteucci's; and, seeing that it harmonises with the view that the electricity in question is dynamical, we prefer it, because, as we have seen, the theory that the electricity is statical is defective, inasmuch as the conditions necessary for the truth of the idea have not been shown to exist, while we see no reason for refusing to believe in the dynamical or current nature of the electricity. We therefore hold that the statical nature of the electricity in muscle and nerve, and the "torpedo-like" discharge of electricity from these tissues when they are thrown into action, have not been proven; nay, more, we are unable to find sufficient evidence to show that Radcliffe's views regarding these two points are even probable.

#### POOR-LAW MEDICAL OFFICERS' ASSOCIATION OF ENGLAND.

THE annual meeting was not very numerously attended. Dr. J. Rogers, the President, stated that the financial position of the Association was good, and so were the prospects of legislation next year. Dr. Rogers expressed an opinion that it would be well that a member of the House of Commons, such as Mr. Corrance, should be elected President for the ensuing year. On the motion of Mr. Milward of Cardiff, seconded by Dr. Dudfield, Dr. Rogers was unanimously re-elected. Dr. Dudfield, Dr. E. Jones, Dr. J. Dixon, Dr. C. Welch, Dr. Brett (Watford), Dr. Clarke (Leicester), Mr. Mathews (Horsham), and Dr. Sheen (Cardiff), were elected Vice-Presidents. The officers were re-elected.

Dr. Rogers delivered an address. He was unable to say why Dr. Brady had not carried out his announced intention, unless from ill-health. Mr. W. H. Smith had gallantly striven for a Royal Commission on Metropolitan Pauperism, but before a house which might at any time have been counted out. He referred to the formation of the Poor-law Committee of the British Medical Association, and their joint deputations to Mr. Goschen on the subject of the reorganisation of the Poor-law medical service, and the institution of sickness-returns, and to the medical officer of the Privy Council on the vaccination laws and regulations. He regretted that the Sanitary Commission had not recommended the employment of Poor-law medical officers in a sanitary capacity in London as well as the country. Poor-law inquiries should be conducted by medical men, not by "barristers who owed their favours exclusively to court favouritism or intrigue." The highest offices in the Poor-law medical service should be given to district officers, and thus a path of promotion would be open, as in the church and at the bar. He summed up the arguments against the present consolidation of vaccination offices. His address to the Central Chamber of Agriculture had converted to his views a number of influential noblemen and gentlemen, whose attitude was at first one of hostility, but subsequently of adhesion. He referred at length to Mr. Corrance's intended motion.

A discussion followed, in which Mr. Lord, Mr. Benson Baker, Dr. Stallard, and Mr. Wickham Barnes expressed their concurrence in the views of the President.

THE annual dinner of the Middlesex Hospital Club took place at Willis's Rooms on Friday; G. A. Makins, Esq., in the chair. There was a considerable attendance of old Middlesex men. The meeting passed off successfully.

THE Edinburgh University Club quarterly dinner will be held at St. James's Hall on August 1st; Dr. Lyon Playfair, M.P., in the chair.

ACCORDING to the *Impartial de l'Est*, the celebrated Zouave Jacob, whose supposed cures of paralysis excited much attention in Paris at one time, has come to a miserable end. This journal alleges that he belonged to the 20th Corps in the Army of the Loire, and was shot as a traitor and spy. He kept the Prussians daily informed of the position of the French Army during three months' time.

#### THE WESTMINSTER HOSPITAL.

MR. THOMAS COOKE and Mr. C. Roberts are candidates for the vacant appointment of assistant-surgeon to the hospital. Mr. Cooke is the author of an excellent work on *Operative Anatomy*, and has lengthened and responsible hospital experience. Mr. Roberts, who has had also considerable public experience, is favourably known to the profession by his contributions to its literature. Mr. Pearse, the senior assistant-surgeon, will be promoted to the office of full surgeon.

#### VACCINATION OF FACTORY-WORKERS.

WE have received a copy of a circular letter, drawn up, we believe, by Mr. Robert Baker, Medical Inspector of Factories, addressed to the certifying surgeons under the Factory Act. These gentlemen have, and deserve to have, a very powerful influence over the numerous workpeople who look up to them as advisers and friends, as well as protectors; and it was a wise and kind thought of Mr. Baker to employ this influence to ensure the adoption of vaccination wherever it had been neglected amongst the great number brought under observation. We are assured, and readily believe, that the certifying surgeons have cordially and zealously exerted themselves to discover instances of neglected vaccination, and to get the precaution adopted without delay. Members of our profession are always ready to do any good service in their power, without waiting to secure remuneration for its performance; and as yet no remuneration for this particular service is forthcoming. This is, however, unfair. Some mode of rewarding the extra work asked for and given should be discovered, and we trust that it will be. A grateful acknowledgment of the certifying surgeons' aid is their due; but they deserve substantial recompense as well, and it is alike just and politic to give it.

#### A DESCENDANT OF JENNER.

MR. STEPHEN JENNER, grandnephew of the illustrious author of vaccination, and stated to be almost the only living relative bearing that honoured name, is living, at the age of seventy-five, in bad health, in a poor cottage at Heathfield, in the parish of Berkeley. As a lad, he lived much with Dr. Jenner, and was in course of education for the medical profession, when Dr. Jenner was struck with apoplexy at the breakfast-table (he being the only person present), and died. The loss of his protector arrested his medical training. He has lived a blameless life, eking out slender allowances from parish work by natural and acquired artistic gifts. He has brought up a large family, and is now, in his old age, suffering uncomplainingly from infirmities and necessity. The first claim of such a man is on the gratitude of his country to that splendid benefactor of humanity of whom he is the collateral descendant. We trust that the Civil List may be available for his modest wants; and that whatever that provision may lack in rapidity or generosity of allowance, will, we trust, be forthwith anticipated by the gifts of individuals. There are few in this nation who are not under an immediate and personal obligation to Jenner for the preservation of themselves and their families from a loathsome pestilence, or, at the worst, for its mitigation. Those who do not owe this debt are the few who prefer small-pox to vaccination, who are regardless of their chances of life, or heedless of the personal disfigurement and constitutional deterioration which follow an attack of small-pox unmodified by vaccination. The saving of life from the practice of vaccination—imperfectly as it is still adopted—amounts in this country alone to above fifty-five thousand annually; those rescued from loathsome disease, to between

two and three hundred thousand. If the living population of Great Britain were to show common gratitude, how magnificently would the wants of this descendant of Jenner be supplied, and how few hours would pass before he would be lifted out of want! We do not recognise any particular obligation as incumbent upon our own profession in this matter: it is the great people of these kingdoms who owe a debt to Jenner in their individual and national capacities. We believe, however, that members of the medical profession will sympathise with the nephew of their illustrious colleague; and we shall with much pleasure take care that any sums which may be forwarded to this office shall be made available for the purpose indicated.

#### A NICE COUNTRY VILLAGE.

DR. HENRY STEVENS, one of the Medical Inspectors attached to the Medical Department of the Privy Council Office, has just been making a sanitary inspection of the village or township of Malpas in Cheshire, "It may be stated shortly that, in every conceivable variety of sanitary defect, Malpas village emulates the most neglected inhabited spot that has ever been reported on." The village has the usual amount of bad arrangements for dealing with the disposal of excrement and filth of other descriptions; and in this it is perhaps not so very different from many other places; but in one matter—that of a portion of the water-supply—the arrangement is so novel that it is worth calling attention to. "The scheme," says Dr. Stevens, "for raising the water to the reservoir for distribution is original. An over-shot water-wheel is attached to the pump, with the view that water from the neighbouring sewage-pool would afford sufficient power to raise the purer water to the height and the following is his brief account of it in a sanitary point of view. required." This water-wheel is within two feet of the open tank out of which the water for the village supply is pumped; the result being, as he afterwards says, self-evident, "that the splashing of the wheel throws the sewage to a not inconsiderable extent into the tank that collects the spring-water." The consequence of all these arrangements, ingenious and otherwise, is, that in about five months *one-tenth of the whole population has been stricken down with enteric disease.* Surely something practical should be done to awaken the authority of such a place to a sense of its duties.

#### MEDICAL EXPERTS IN COURTS OF LAW.

MR. LAWSON TAIT writes to us as follows.

The growing evils of expert evidence verily need such reproofs as you reprinted from the *Standard* in your last issue. In a trial for murder, it is perhaps allowable for the defence to make use of any scheme which may be likely to be successful; so that there really may be some excuse for Mrs. Newington's medical witnesses "speaking less with reference to the ascertained circumstances of the case than to frame a theory of their own which might justify a verdict of acquittal." In the matter of actions for damages, however, I differ from the writer in the *Standard*, believing, as I do, that there is no such excuse, and that the conduct of experts in many instances is a scandal to science, and more especially to medicine. A short time ago, I was engaged at Guildhall in a trial for malap Praxis on the part of a dentist, the brief narration of the facts of which may prove of interest to your readers. The plaintiff came to me many months ago, sent by a physician, with a fracture of the alveolar process of the left upper jaw at a spot where the second molar tooth was missing. The alveolar process had necrosed as far as the central incisor; and I removed the sequestrum, along with the corresponding teeth. The patient had no other ailment, and never had had, except an attack of fever and ague. I swore to a most careful investigation for syphilis at the time I first saw him, and to the utter absence of any indication of it. He was under my care for many months, and was seen daily; and yet no indication of syphilis ever presented itself to me. The plaintiff swore he had never contracted any venereal disease; and though he was a sailor—a point on which great stress was laid by the defence—the fact that at twenty-nine he had worked himself from before the mast to be first mate of a first-class trader, and the high character he held from his superiors, were enough to show good grounds for believing him. He also swore to extremely violent measures on behalf of the dentist. Though pressed by the judge, I declined to give any opinion as to the sequence of injury and the disease. I merely swore to the facts of the case as they came before me: that I had never seen any disease produce such

results; that, if produced by violence, it must have been excessive; and that the plaintiff had certainly not had syphilis. My surprise was not, then, small when I heard two well known London hospital surgeons, who followed me in the box, declare that such results were frequently the result of syphilis, without any violence; that disease of the alveolar processes, without any other supporting condition in the palate or elsewhere, was frequently caused by tertiary syphilis; and that, although they had only seen the plaintiff on the morning of the trial for a few seconds, and had no knowledge whatever of his history or his case save what fell from me, they believed that syphilis was the cause of all the mischief. I think I need scarcely say that the jury, almost without consultation, found most substantial damages for the plaintiff, discarding altogether this unfair attempt by the defence not only to damage the cause of a poor man, but to damage his character; for what could be meaner than to throw the stigma of syphilis on a man because he was only a sailor?

#### THE SMALL-POX EPIDEMIC IN ST. PETERSBURG.

FROM June 14th to 25th, both days inclusive, there occurred 440 new cases and 210 deaths. The total numbers since the commencement of the epidemic (Aug. 17th, 1870) to June 26th, 1871, are as follows.

	Cases.	Recoveries.	Deaths.
Male .....	5,566 .....	1,823 .....	1,515
Female .....	1,764 .....	972 .....	663
Total .....	5,330 .....	2,795 .....	2,178

#### HOSPITAL FINANCE.

THERE is, we believe, a general conviction among those who have devoted their attention to the statistics of hospitals, that the reconciliation of the discrepancies in the rates of income, and especially of expenditure, of these institutions, is among the most perplexing problems the solution of which could be offered to the ingenuity of any one. Our readers will call to mind that, in the JOURNAL of October 17th, 1868, there was published a tabulated statement, which presented the great variations which existed in the cost of maintenance of patients in the different hospitals. The subject has been ably investigated by Mr. Charles Kemble, President of the Bath Royal United Hospital; and he has just published the result of his examination. The way of escape from the difficulty lies, he suggests, not only in an uniform system of account-keeping, but in "an accurate classification of the several items of hospital expenditure". "The simple, natural, and common-sense aspect of the statement", he says, "almost forbids its enunciation; and he only ventures to commit it to print, because as yet it seems to have been practically overlooked." We place Mr. Kemble's suggestions before our readers; remarking merely that we have no doubt, if carried out, they would remove much of the perplexity in which hospital finance has been hitherto involved.

"There are obviously two general heads under which hospital expenditure should be distributed: I. The collection of its income; II. The application of that income. Take these in order, and causes for variation of cost of beds or patients will multiply as we advance.

"I. The collection of income makes the first claim upon income; and this will vary with the sources from whence income is derived. 1. An income drawn from funded property will entail no cost beyond a power enabling the banker or treasurer to receive the dividends. 2. An income derived from voluntary contributions and subscriptions will involve an outlay of from five to ten per cent. for collecting. 3. An income derived from lands and houses will involve a much higher charge. Professional assistance has to be obtained, and charges for the management as well as repairs of estates form a considerable item of expenditure in such cases. It is obviously unfair and delusive to compare the cost of hospitals supported by these different methods, unless in the first instance the cost of collection is deducted from income in each case.

"II. The second general head of expenditure is the application of income to the purposes of the hospital. Here a triple division is necessary. 1. The first liability incurred is for the building. This may be (a) freehold, involving no annual outlay for rent; or (b) held on condition of a yearly payment. To make a comparison between two hospitals differently placed in this respect, we must either add in the one case interest for the value of site and cost of the building, or subtract the rent from the yearly outlay of the other. 2. The second head will

comprise establishment charges, permanent and unvarying; i.e., such expenditure as must be entailed upon a hospital before any patient can be received. These will be—*a.* Rates and taxes; *b.* Officers' salaries and board; *c.* Nurses' wages and board; *d.* Servants' wages and board; *e.* Fuel and lights. These expenses must be incurred upon an estimate of the probable number of patients to be expected. Experience alone can show if the preparations are on a suitable scale, or are too large or too small. 3. The third head will be the personal expenses of the patients, who should be divided into two groups.

"A. *In-Patients.* These consist of—*a.* Male medical; *b.* Male surgical; *c.* Female medical; *d.* Female surgical; *e.* Children medical; *f.* Children surgical; *g.* Special cases admitted to some hospitals, excluded from others. The personal expenses of patients in these several groups are—*a.* Medicine and surgical appliances; *b.* Food; *c.* Washing; *d.* Printing; *e.* Wear and tear of furniture; *f.* Repair and cleansing of premises. The age and character of the buildings of necessity very considerably affect the charges under this last head.

"B. *Out-Patients.* *a.* Visited at home; *b.* Relieved at hospital.

"The cost of out-patients arises not only from the medicine dispensed, but medical attendance, dispenser, porters, printing, and wear of furniture, so that the out-patient department absorbs a much larger proportion of revenue than is frequently attributed to it.

"The cost of out-patients is more affected by numbers than at first sight may appear. If the number be small, the staff required to attend to the in-patients can without difficulty undertake the additional duty, and the charge upon the hospital is little more than the medicine given away. But when the numbers become such as to demand more time than the in-patient staff can afford, the out-patient department becomes at once chargeable with salaries for dispenser, porter, and assistants.

"There are also other expenses incurred in some hospitals, which should be set out separately. These are, a medical school; a museum and library; an incurable department; special funds; e.g., Samaritan Fund, Nurses' Pension Fund, Flannel Charity, and the like. These heads of expenditure should be kept distinct, and shown in the balance-sheet. In some cases it may not be practicable to keep a minute account of every particular here suggested; but the general outline may be usefully adopted, and the more fully it can be filled up the more useful will the account be found."

#### AN IMPERIAL SAVANT.

AT the visit of the Emperor of Brazil to the Museum of the Royal College of Surgeons of England, on the 21st instant, His Majesty displayed a remarkable familiarity with the principal subjects illustrated in the museum, and considerable acquaintance with recent English scientific literature; showing by his remarks, and the thoughtful interest which he took in various specimens in the collection, that comparative anatomy and zoology are included among the numerous branches of knowledge in which he is versed. He particularly wished to see the skeleton of the *Ornithorynchus* and the allied monotreme the *Echidna*, and placed them side by side to observe their distinguishing characteristics. He was also much interested in the young hippopotamus. In the pathological department, Professor Wilson's dermatological collection and the extensive series of calculi particularly attracted His Majesty's attention. On leaving, he expressed himself highly gratified with the arrangement of the collection and the facilities which it afforded for study. On the same morning he paid an early visit to Dr. Hooker, F.R.S., at Kew, to Professor Owen, F.R.S., at Sheen Lodge, and to Earl Russell in Richmond Park. In the afternoon, accompanied by the Empress, he met a select party of men eminent in various branches of science at the house of Mr. W. Spottiswoode, treasurer of the Royal Society, the following being among those present: Lord Houghton, the Dean of Westminster, Professor Huxley, Sir Philip de M. Grey Egerton, Dr. Hooker, Dr. Sharpey, Dr. Sibson, Mr. Bowman, Professor Ramsay, Dr. Carpenter, Dr. A. Farre, Professor Flower, Dr. Gull, Mr. Lassell, Sir Charles Wheatstone, Mr. Sylvester, Dr. Gueneau de Mussy, Captain Galton, etc. His Majesty appeared much pleased with the opportunity of becoming personally acquainted with men, with many of whose names he had long been familiar, and said that he should, on his return to Brazil, follow the course of English scientific investigation with still greater interest than before. On the following day the Emperor visited Oxford, and is now engaged making a tour of the provinces.

## SMALL-POX IN SOUTH AMERICA.

THE small-pox, which was so terribly epidemic in Buenos Ayres, has, it appears, broken out in Monte Video in an epidemic form. For some months, it is reported, the mortality has been greatly raised by small-pox deaths; and now a very bad type of it is raging. The deaths are stated to be as many as fifteen daily; and the epidemic appears, from latest advices, to be increasing.

## THE SANITARY STATE OF LEEDS.

THE Lords of Her Majesty's Council have just issued a report on the sanitary state of Leeds. It relates to a matter of very great importance (the town authorities of Leeds having an injunction against them for turning their sewage into the river Aire), and is an examination of the health-status of a very large manufacturing town exceptionally circumstanced. The report is by Mr. J. Netten Radcliffe, and consists of thirty-five pages of closely printed foolscap, besides an appendix of tables.

## THE CONTAGIOUS DISEASES ACTS.

A VERY excited deputation waited last week upon the Home Secretary, urged the immediate repeal of the Acts, and threatened a renewal of the repulsive flood of literature which has already been let loose by the Society in only too broad and frequent rivulets, into decent homes and amongst unpolluted Englishwomen. Energetic protests have been made on behalf of public decency and morality against the forced publicity which it is proposed to give to a class of literature open to most of the objections which insured the suppression of the *Confessional Unmasked*. But there is reason to fear that the moderate, sensible, and deliberate report of the Royal Commission has tended rather to increase than to abate the *furia francese* of the feminine opponents of the Acts and their allies.

## THE ROYAL INSTITUTION OF CORNWALL.

WE have received the programme of the annual excursion of the Royal Institution of Cornwall. It will take place on the 14th and 15th of August; in the week, therefore, following that in which the meeting of the British Medical Association will be held in Plymouth. The district visited will be that lying west of Penzance—one rich in objects of antiquarian, geological, mining, and picturesque interest; and those of our Associates who may be able to remain after the annual meeting and join the excursion will, we doubt not, meet with a cordial reception, and find much mental gratification. The price of a ticket for the ten days—not including railway fare or hotel accommodation—is sixteen shillings. Dr. C. Barham of Truro has kindly consented to act as the medium for receiving applications, which should be made not later than August 5th, and be accompanied with the price of the ticket. The presentation of the excursion-ticket at any station on the Cornwall or West Cornwall Railways will entitle the holder to a return ticket at single fare, available for August 12th to 15th, inclusive.

## SANITARY LEGISLATION.

IN the House of Commons, on Tuesday last, Sir C. Adderley obtained leave to bring in a Bill to consolidate and amend the laws relating to public health and local governments. He explained that the measure was simply the report of the Sanitary Commission in the form of a Bill. Having pointed out the necessity for the consolidation of the sanitary laws and sanitary authorities, and of removing the anomaly that the carrying out of the sanitary laws was entirely optional, he said that the first part of his Bill proposed to repeal all sanitary acts; and, though the Bill consisted of 450 clauses, nine-tenths of them would be inserted merely for the purpose of re-enactment. The second part of the Bill divided the whole of the kingdom into sanitary districts, so that each should have its sanitary authority; and there would be no place without its sanitary authority, and only one such authority in every place. The next thing which the Bill professed to do was to simplify the area

of jurisdiction; in fact, to follow the example which had been set in Hampshire by Lord Eversley. The next part of the Bill gave powers for water companies, sewerage, street, highways, guardians, and all kinds of local improvements, among which would be included markets, burial bills, and other things in the same category. The rest of the Bill would provide for the purpose of audit. If the house would allow him to introduce the Bill he did not wish to carry it any further at present; but it could be circulated throughout the country during the recess, and he hoped to be able to carry it into law during the next session.

## THE GERMAN LOSSES BY SICKNESS IN THE WAR.

THE *Pall Mall Gazette* states, on German authority, that there is an unwillingness in influential circles to allow the full extent of the German losses in the late war to transpire. The list of killed and wounded was made public as it could not be avoided, although in a very inaccurate and incomplete manner. On the other hand, there has been a determined objection to giving statements of figures with regard to the devastation brought about by sickness. Vague forms of speech were reckoned satisfactory, and it was boldly asserted on several occasions that the health of the army was excellent, "better than in times of peace," although the endless convoys of sick, as well as thousands of soldiers' letters, gave the lie to such statements. A semi-official corroboration now suddenly appears of the worst rumours which were circulated in process of time. The Central Bureau of Information in Berlin, under the inspection of the highest military authorities, has published a report of its work, with interesting statistical figures. It appears from this report that the institution has within the space of twelve months authenticated 633,000 sick and wounded cases, and that of these only 78,000 belonged to the French, the remaining 555,000 to the German army. The circumstance that only 46,000 of these were South Germans, and that nearly 508,000 were north Germans, shows by the disproportion of the numbers, that the bureau had really been occupied with the North German army. The frightful figures, which besides make no claim to completeness, are, according to this, far below the truth. And if we reckon the wounded at a hundred thousand in round numbers, we shall certainly still be within the truth if we estimate the number of the unwounded sick at half a million. How many of these have died or drag about an incurable sickly body is more than we can say, failing the necessary information. The figure must, however, be a terrible one.

## ASIATIC CHOLERA.

THE Registrar-General points out that Asiatic cholera, as it was a painful duty to announce early last June, is entering Western Europe through Russia, where, Dr. Zuelzer says, it is fast advancing on the German frontiers. In the second week of this month it broke out in Wilkowszki (a town of Poland, on the road to Königsberg, west of the Niemen), where thirty-four deaths occurred in a few days. The epidemic has prevailed in Wilna for four weeks, and from ten to fifteen deaths are reported daily. At its present rate of progress it may reach Germany in two or three weeks. The *Journal de St. Petersburg* of the 21st instant says:—The *Police Gazette* of St. Petersburg published on the 18th instant the following return of cholera cases—patients, 518; new cases, 67; cured, 33; dead, 27. The same newspaper stated that on the 19th instant there were still under medical treatment 525 persons. Since the appearance of cholera on the 29th of August, 1870, to the 19th of July, 1871, there have been 6,072 cases, 3,040 cures, 2,485 deaths. The *Caucasus* newspaper says it is known from reliable sources that the cholera which has this year broken out in Persia originated at Arbil, on the route from Taurida to Sirab and Zandrak. Surgeon-Major Atchison, in the sonorous sentences which have before secured for him the public ear on similar topics, points out the immediate connexion of epidemic cholera with water-poisoning and defective sanitation of air and soil. Many other correspondents follow him, and an anticipatory cholera-panic is setting in, which will probably

have beneficial sanitary results in quickening the long-delayed legislation. There is still, however, room to anticipate that the fears entertained may not be realised. We have for some months kept our readers provided with the materials of forecast.

#### ALLEGED OUTBREAK OF PLAGUE IN PERSIA.

It is reported that a disease supposed to be plague has broken out in a Persian town close to the Turkish frontier, and that the Ottoman authorities are taking stringent measures to prevent communication between their own country and the affected place.

#### VACCINATION AT THE CAPE OF GOOD HOPE.

VACCINATION and revaccination have recently been receiving attention on the part of the colonial authorities at the Cape of Good Hope; for the Government has been urging the public there to avail themselves of the protection which the operation affords against the sad results of small-pox. We hear that many thousands of persons have profited by the advice, though there appear to be some who are of the same mind with the opposers of vaccination here.

#### QUARANTINE IN PERSIA.

SOME alteration has recently been made in the quarantine regulations in Turkey, so far as they regard the passage of vessels through the Dardanelles. Ships with foul bills of health are in future to be allowed to pass through on condition that, when they enter the Bosphorus, they take on board health-officers, and are towed right through, without stopping, into the Sea of Marmora. By this course there will be a saving of the time (we think ten days) during which, under the old regulations, the vessels would have to wait in quarantine before passing through the Straits.

### SCOTLAND.

#### DEATH WHILE UNDER THE INFLUENCE OF CHLOROFORM.

IN our Hospital Reports we publish the details of another death from chloroform. The unfortunate occurrence took place at the Royal Infirmary, Aberdeen. Death appears to have resulted, as Dr. Pirrie and his colleagues believe, from mixed causes, the advanced conditions of muscular disease of the heart being most influential. The presence of so large a quantity of blood in the right side of the heart compared with that in the left does not, according to the best authorities, lend probability to the view that death resulted from gradual asphyxia.

### IRELAND.

THE Irish Poor-law Officers' Association has issued an admirable report and statement of its objects. This Society is conducted with great vigour and judgment; and a continually larger number of dispensary physicians manifest their approval of its vigorous and patriotic efforts, which are solely directed to improvements in the administration of medical relief and the status of medical officers.

#### OUR IRISH COLLEAGUES.

WE are glad to hear that the Rev. Dr. Haughton, Dr. Beatty, and Mr. Macnamara (President of the College of Surgeons of Ireland), will be among the associates of Ireland who will join in the annual meeting of the Association at Plymouth on August 7th. The direct route from Dublin to Plymouth is by sea; and this route will have many attractions for those who possess the *robur et as triplex* which will enable them to brave with impunity the dangers, and enjoy with keenness the pleasures, of a short sea-trip. We can promise them a warm welcome at the end of their journey.

#### THE LIMERICK UNION AND ITS MEDICAL OFFICERS.

At a meeting of the Board of Guardians of the Limerick Union on the 19th instant, it was proposed to raise the salaries of the dispensary medical officers. This proposal was, however, met by an amendment,

which its proposer, Mr. Enright, supported by remarking that, "wherever those young gentlemen (the dispensary doctors) may have been manufactured, their appointments under the Poor-law Board tended more to the advancement and the remunerative results of the profession than anything else, in procuring employment, and in bringing them into contact with the people of the neighbourhood in which they are located; and, further, he could assure the Board that, if the situations of the medical doctors were put up for competition, they would find many candidates." He proposed an amendment, that the salaries of the medical officers remain as they are. Mr. Frennd seconded the amendment, which was carried by a large majority, and the resolution declared lost. After the disposal of some routine business, the Board adjourned.

#### THE CASE OF CONSTABLE TALBOT.

THE investigation into the death of Constable Talbot, which is at present going on in Dublin, has some special interest in a medico-legal point of view. The man was shot through the head, the bullet fracturing the atlas. He died four or five days after the receipt of the injury; and, at the necropsy, as described by Mr. Vesey and Mr. William Stokes, there was found inflammation of the spinal cord and its membranes at the seat of fracture. A sharp discussion arose at the inquest as to the possibility of death having been the result of hæmorrhage from a wound of the occipital artery inflicted in an attempt to remove the bullet. The injury at the base of the skull was, however, of an inevitably fatal character; and there seemed to be nothing to justify the hypothesis to which we have referred above. It is not surprising that Mr. Stokes warmly resented its suggestion.

#### LECTURES ON UTERINE DISPLACEMENTS.

DR. PROTHEROE SMITH has delivered a course of lectures at the Hospital for Women on "Flexions, Torsions, and Displacements of the Uterus"; in the course of which he reviewed the literature of twenty-five years on uterine dislocations. After giving the opinions, diagnosis, modes and means of treatment, advocated by various writers on the subject, he stated the grounds for his disapproving of intravaginal and intrauterine instruments as a rule. He accounted for the frequency of such displacements not as being only consequent upon the ordinary causes assigned for such abnormal conditions, but, after some novel views of the physiology of menstruation, he affirmed his belief that both proximate and exciting cause might be legitimately looked for in the incessant and excessive efforts of menstruation of the unmarried and of the sterile, contrary to the primeval law given to women to "increase and multiply," which provided for an interruption of the catamenia by utero-gestation and lactation. Thus injurious results ensue as in other organs of the body when used beyond the limits imposed by Nature, as much as in other instances from dystocia and non-lactation. Dr. Protheroe Smith observed also that flexions and other uterine derangements were not unfrequently caused by loss of the angle of  $140^\circ$ , which in a normal state exists between the spinal axis and that of the pelvis. This he proposed to remedy, after the removal of any organic or inflammatory disease of the uterus and its adjuncts, by the restoration of the natural lumbopelvic angle of  $140^\circ$ , by means of his pelvic band. In a word, he had experienced the greatest success in the treatment of uterine deflexions since he had adopted this mechanical aid *externally*, and had relinquished, as far as possible, the vaginal and uterine appliances which formerly he, as well as others, had used more generally. Dr. Protheroe Smith terminated his course of lectures by offering as "*ultima* of belief" fifteen practical conclusions, from which we quote "that spino-pelvic deformity is a frequent cause of derangement of the contained viscera; that their frequency is in keeping with the advance of civilisation, and that they are, with few exceptions, *menstrual* as to the period of their occurrence; that the primary condition of the uterus itself, forming a predisposing, and, at times, the exciting cause of flexions, is hyperæmia or inflammatory engorgement, the frequent result of excessive irritation and uninterrupted menstrual efforts, etc.; that in cases requiring intravaginal or intrauterine treatment, all inflammatory and other organic affections of the uterus and neighbouring viscera should *first* be removed, and *extreme* care and gentleness observed, and *all* pain avoided; that instrumental aid, by means of the 'pelvic band', should be employed externally whenever indicated by spino-pelvic deformity; and, *as a rule*, all intravaginal and intrauterine instruments, especially when metallic, should, as far as possible, be avoided in treatment."

## ASSOCIATION INTELLIGENCE.

BRITISH MEDICAL ASSOCIATION:  
ANNUAL MEETING.

THE Thirty-ninth Annual Meeting of the British Medical Association will be held in Plymouth, on Tuesday, Wednesday, Thursday, and Friday, the 8th, 9th, 10th, and 11th of August next.

*President*—E. CHARLTON, M.D., D.C.L., Physician to the New-castle-upon-Tyne Infirmary.

*President-elect*—JOHN WHIPPLE, Esq., F.R.C.S., Consulting Surgeon to the South Devon and East Cornwall Hospital.

An *Address in Medicine* will be delivered by GEORGE JOHNSON, M.D., F.R.C.P., Professor of Medicine in King's College, London.

An *Address in Surgery* will be delivered by JOSEPH LISTER, Esq., F.R.S., Professor of Clinical Surgery in the University of Edinburgh.

The business of the meeting will be conducted under four Sections.

**SECTION A. MEDICINE.**—*President*, Dr. Barham, Truro. *Vice-Presidents*—Dr. Quain, F.R.S., London; Inspector-General Smart, M.D., C.B., R.N., Penge, Surrey. *Secretaries*—Dr. Clay, Windsor Villas, Plymouth; Dr. Wade, Temple Row, Birmingham.

**SECTION B. SURGERY.**—*President*—Joseph May, Esq., Stoke, Devonport. *Vice-Presidents*—P. C. De la Garde, Esq., Exeter; Deputy-Inspector-General Longmore, C.B., Netley. *Secretaries*—W. P. Swain, Esq., Ker Street, Devonport; C. Steele, Esq., Meridian Place, Clifton, Bristol.

**SECTION C. MIDWIFERY.**—*President*—Dr. Beatty, Dublin. *Vice-Presidents*—Dr. Swayne, Clifton, Bristol; Dr. Alfred Meadows, London. *Secretaries*—Dr. John Rolston, Stoke, Devonport; Dr. Phillips, 26, Finsbury Square, London, E.C.

**SECTION D. PUBLIC MEDICINE.**—*President*—Dr. A. P. Stewart, London. *Vice-Presidents*—P. W. Swain, Esq., Stoke, Devonport; Dr. Beddoe, Clifton, Bristol. *Secretaries*—Dr. Row, Ker Street, Devonport; David Davies, Esq., 2, Queen Square, Bristol.

## TUESDAY, August 8th.

The meetings this day will be held at the Royal Hotel, PLYMOUTH.

1 P.M.—MEETING OF COMMITTEE OF COUNCIL.

3 P.M.—MEETING OF GENERAL COUNCIL.

8 P.M.—FIRST GENERAL MEETING. *Business*: a. Reception of Congratulatory Address from Plymouth Corporation; b. President's Address; c. Vote of thanks to the President; d. Report of Council, and Discussion thereon; e. Election of General Secretary; f. Election of Auditors; g. Report of Medical Benevolent Fund; h. Presentation of Hastings Medal.

## WEDNESDAY, August 9th.

8.30 A.M.—PUBLIC BREAKFAST—Royal Hotel, DEVONPORT.

9.30 A.M.—MEETING OF NEW COUNCIL—Royal Hotel, DEVONPORT.

11 A.M.—SECOND GENERAL MEETING—Town Hall, DEVONPORT. *Business*: a. Reception of Congratulatory Address from Devonport Corporation; b. To appoint place of meeting for 1872, and President-elect; c. Address in Medicine by Dr. GEORGE JOHNSON.

1 P.M.—Adjourn.

2 P.M.—MEETINGS OF SECTIONS—Royal Hotel, PLYMOUTH.

9 P.M.—PRESIDENT'S SOIRÉE—Assembly Rooms, Royal Hotel, PLYMOUTH.

## THURSDAY, August 10th.

9.30 A.M.—MEETING OF COMMITTEE ON REGISTRATION OF DISEASE—Public Dispensary, Catherine Street, PLYMOUTH.

10 A.M.—THIRD GENERAL MEETING. *Business*: Reports of Committees—Royal Hotel, PLYMOUTH.

11 A.M.—ADDRESS IN SURGERY, by Professor LISTER, F.R.S.—Royal Hotel, PLYMOUTH.

2 P.M.—MEETINGS OF SECTIONS—Royal Hotel, PLYMOUTH.

6.30 P.M.—PUBLIC DINNER—St. George's Hall, STONEHOUSE. For Dinner Tickets, an early application (enclosing One Guinea) should be made to P. W. Swain, Esq., F.R.C.S., Stoke, Devonport. The services of the far-famed Band of the Royal Marines have been engaged for this occasion.

## FRIDAY, August 11th.

10 A.M.—MEETINGS OF SECTIONS—Royal Hotel, PLYMOUTH.

2 P.M.—CONCLUDING GENERAL MEETING—Royal Hotel, PLYMOUTH.

A RECEPTION ROOM will be opened at the Royal Eye Infirmary,

close by the Plymouth Railway Station. Members and others who require information with respect to the meeting are requested to make application in this room. Information as to Lodgings will be furnished there.

Members are requested to proceed to the Reception-Room immediately on their arrival, to enter their names and addresses, and to obtain the tickets necessary to secure admission to all the proceedings.

**HOTELS.**—The principal hotels are, at PLYMOUTH, the Royal Hotel, the Duke of Cornwall, the Globe, the Albion, Chubb's Hotel, Farley's Hotel, Harvey's Hotel; at DEVONPORT, the Royal Hotel, Thomas's Hotel, and the Crown Hotel.

The GUIDE-BOOKS FOR DEVON AND CORNWALL are: Murray's *Handbook of Devon and Cornwall*; Black's *Guide to Devon and Cornwall*; Blight's *Week at the Land's End*; Rev. — John's *Week at the Lizard*; and, for Plymouth and the neighbourhood, Brendon's and Luke's Guide-books—both by Ll. Jewitt, F.S.A.

\*.\* GENTLEMEN INTENDING TO VISIT PLYMOUTH during the meeting are requested to send their names to Dr. Littleton, the Local Secretary, 1, Lansdowne Place, Plymouth.

**NOTICES OF MOTION.**—The following notices have been given.

The PRESIDENT OF THE COUNCIL: Rule 4. To insert "President-elect", and to omit "Secretary".—Rule 6. To expunge this rule, and to substitute the following: "Each retiring President of the Association and President of Council shall be appointed a Vice-President for life by a vote of the members at the Annual Meeting."—Rule 7. To add "the Vice-Presidents" after President-elect; to insert the word "and" between President of the Council and Treasurer, and to erase "and the Secretary".—Rule 8. In this and every rule where "District" is prefixed to Branch, to erase the word "District", and to erase the words "the Secretary of the Association".—Rule 9. To omit the words between "The President of the Council" and "shall be elected".—Rule 10. To omit the words between "The Treasurer" and "shall be elected".—Rule 11. To erase the words after "There shall be one paid Secretary" in first section, and to substitute "who shall reside in London, and devote his whole time to the business management of the Association and of the JOURNAL office". To erase the words "otherwise" in seventh line and "an annual or special" in eighth line, and to insert "each Annual Meeting".—Rule 13. To erase the words "Secretary shall call", and to substitute "President of Council shall direct to be called".—Rule 14. Between "shall" and "be recommended", to insert "express his desire in writing, and shall be".—Rule 15. To add "Members may be admitted on and after July 1st in each year, and the subscription for such part of a year shall be half a guinea". To erase the words after "such member" in eighth line, and to substitute "as long as his subscriptions remain unpaid, provided due notice shall have been given of such withholding".—Rule 16. To erase the words after "from his" in fourth line, and to substitute "liabilities to the Association".—Rule 24. In tenth line, to insert "a copy of the laws" between "Association" and "and".

Dr. STEELE (Liverpool): Election of Committee of Council. Every associate, who is a member of the Council, and desirous of a seat on the Committee of Council, shall send to the General Secretary, not later than months prior to the Annual Meeting of the Association, a declaration signed by himself, and in the following terms: "I, A. B., of C., member of the British Medical Association, hereby declare that I am a candidate for a seat on the Committee of Council of the said Association. (Signed) ———." Together with a nomination-paper signed by six members of the Association, in the following terms: "We, the undersigned, members of the British Medical Association, certify that A. B., of C., is a fit and proper person to be a member of the Committee of Council of the said Association." The names of the eligible candidates, with the names of the six associates by whom they shall have been respectively nominated, shall be published in the BRITISH MEDICAL JOURNAL not later than months prior to the Annual Meeting of the Association.

Mr. NICHOLSON (Hull): To alter Law 16, line 2. For "three", insert "two".

Dr. WADE (Birmingham): In Law 8, Paragraph No. 3, of the duties of Council, to alter "ten" into "twenty-five"; and to omit the words "and one Secretary from each Branch".

INVITATION TO TORQUAY.—The members of the medical profession at Torquay request the pleasure of the company at luncheon, on Saturday, August 12th, at 3 o'clock, of any member of the British Medical Association residing beyond fifty miles from the place. Their object in this limitation as to distance is that of furnishing an opportunity to strangers unfamiliar with Devonshire to become acquainted with Torquay and its immediate neighbourhood. Any member who may wish to favour them with his presence, will oblige by notifying the same at

his early convenience—and not later than on the Wednesday of the Plymouth meeting—to the Honorary Secretary, Dr. Powell, Infirmary, Torquay.

**SPECIAL RAILWAY ARRANGEMENTS.**—First and second class ordinary and express return tickets issued at any Station on the Bristol and Exeter Railway, or on the South Devon, Cornwall, or West Cornwall Railways, on August 7th and following days, will be available for the return journey to and from Plymouth any day up to and including Monday, Aug. 21st. First and second class return tickets, at single fare for the double journey, available as above, may be issued from any Station on these lines to Plymouth, or from Plymouth to any South Devon, Cornwall, or West Cornwall station, on August 7th and following days to August 21st inclusive, to the members of the *British Medical Association* producing a certificate or the Association card of membership. Unless such documents be produced, return tickets at ordinary or express fares must be issued. When tickets at single fare for the double journey are issued, the booking clerks must write "return" upon them, and place their initials below the word "return". Ordinary tickets endorsed "return" will be available by express trains without payment of the difference of fare. The South Devon, Cornwall, and West Cornwall Railways have also promised to convey any instruments, medical and surgical appliances, etc., for the Annual Museum, at *half the usual fares*, at the owner's risk.

**EXCURSIONS, ETC.**—The Local Committee appointed by "The Three Towns", Plymouth, Devonport, and Stonehouse, to prepare for the annual meeting of the British Medical Association in 1871, have much pleasure in acquainting the members that they have succeeded in obtaining the cordial cooperation and assistance of the civil and military authorities; so that every facility will be furnished them for inspecting this naval and military arsenal; Her Majesty's ships of war in the Hamoaze and Plymouth Sound; Her Majesty's dockyards at Devonport and Keyham; the Royal William Victualling Yard and the naval and military hospitals in Stonehouse; the Breakwater and its lighthouse; the Eddystone Lighthouse; the Plymouth Citadel, the Hoe, and the forts recently erected within a radius of five miles.

By the kind permission of His Grace the Duke of Bedford, the Right Honourables the Earl of Mount Edgcumbe, the Earl of St. Germans, and the Earl of Morley, and other gentlemen, opportunities will be offered to the members of surveying the grounds and the extensive views commanded in the parks attached to their mansions on the banks of the Tamar and Plym; whereby they will be enabled to pass in review the objects before-named, as well as the magazines at Bull Point; Antony House, the seat of W. H. Pole-Carew, Esq., whereat is preserved Holbein's portrait of Dr. Butts, Physician to Henry VIII; Ince Castle, the residence (*temp.* Charles II.) of the Wit of Cornwall, Killebrew; St. German's Church, the site of Cornwall's ancient Cathedral, and Port Eliot (the ancient Priory); Trematon Castle, the residence of the Norman Earls of Cornwall; the late Brunel's master-piece, the Royal Albert Bridge at Saltash; Landulph Church; Buckland Abbey, the seat of Drake, the great circumnavigator; Maristowe; Cothele House; Pentillic Castle; Morwell Rocks; Harewood, the scene of the fair Elfreda's treachery; and other objects of interest in a trip of twenty miles by steamboat.

A steamer will be engaged to make short trips daily, and at stated hours, during the visit of the Association, thus enabling those members who may not be desirous of hearing the delivery of certain papers, to spend their time agreeably in viewing the rich scenery of the port of Plymouth.

Other excursions will be arranged, with the sanction of the Directors, etc., of the Railways—to Launceston Castle, the Ancient Cornish stronghold; to the Saxon Abbey at Tavistock; to Endsleigh Cottage; and to the wild and romantic scenery of Dartmoor.

**ANNUAL MUSEUM.**—The "Annual Museum" of this Association will be open during the four days of the meeting, for the exhibition of:

1. The latest inventions in medical and surgical instruments and appliances of every kind. Also, for the special exhibition of ancient and modern fracture apparatus, or diagrams of such, thus setting forth the history of the treatment of fractures from the earliest records down to the present day.

2. New drugs and their preparations.

3. New articles of diet for invalids.

4. Pathological Specimens; also photographs, casts, etc., illustrating disease.

5. New works on medicine, surgery, etc.

6. Models or drawings of any object of professional interest not included in the above list.

*Notice to Exhibitors.*—Application should be made as soon as possible; at the same time giving a list of the objects to be exhibited, and mentioning the space required. All objects sent must have a de-

scription attached. Parcels for the Museum should be addressed—"British Medical Association, the Assembly Rooms, Royal Hotel, Plymouth; care of H. Greenway, Esq." They must be delivered on or before July 31st, and be removed within three days after the termination of the meeting. Expenses of carriage and all risk must be borne by the exhibitors. All instruments and other articles intended for the Local Museum will be conveyed at owners' risks for *half the usual fares* on the Bristol and Exeter, South Devon, and Cornwall lines of railway. A card, bearing the name and address of the exhibitor, must be enclosed in each package, ready to be fixed on the outside. All communications respecting the Museum to be addressed to "Henry Greenway, Esq., Surgeon, Plymouth", the Secretary for that department.

**PAPERS.**—The following papers have been promised.

C. Barham, M.D. 1. Diseases of Plymouth during the Second Quarter of last Century (1725-1750). 2. Diseases of Cornish Miners. Tilbury Fox, M.D. 1. Hydroa. 2. A Note on Phtheiriasis, erroneously styled Prurigo.

J. Crichton Browne, M.D. Syphilis and Insanity.

J. Althaus, M.D. Paralysis of the Bladder, and its Treatment by the constant Galvanic Current.

T. J. Austin, M.R.C.S. Medical Electrification.

Thomas Littleton, M.B. The Effects of Submarine Descent on Man, and the Limits of his Capability.

William Roberts, M.D. Intemperance as a Cause of Chronic Bright's Disease.

W. H. O. Sankey, M.D. The Relation and Diagnosis between General Paresis and Locomotor Ataxy.

D. De Berdt Hovell, F.R.C.S. 1. The different Therapeutic Indications of Rheumatism and Neuralgia: with Remarks on Rheumatism as a Sequela of Diphtheria. 2. Uterine Truss or Support for Post Partum Hæmorrhage.

George Southam, F.R.C.S. Excision of the Tongue.

T. H. Bartleet, M.B., F.R.C.S. Splint for Excision.

Edward Lund, F.R.C.S. Antisepticity in Surgery.

Furneaux Jordan, F.R.C.S. The Extension of Inflammation from the Epididymis to the Urethra: with Cases.

Thomas Beatty, M.D. 1. Fibro-cystic Disease of the Uterus. 2. The Radical Cure of Retroflexion of the Uterus.

Robert Barnes, M.D. Hypertrophic Elongation of the Cervix Uteri.

J. Braxton Hicks, M.D., F.R.S. 1. A Rare Form of Post Partum Hæmorrhage. 2. The Reduction of Inversion of the Uterus: illustrated by six Cases.

E. J. Tilt, M.D. Hysteria, and the various ways in which it has been viewed by Pathologists.

A. Meadows, M.D. The Treatment of Fibrous Tumours of the Uterus.

J. G. Swayne, M.D. Treatment of Hæmorrhage arising from Retention of the Secundines after Abortion.

Thomas Underhill, M.D. The Treatment of certain Cases of Placenta Prævia and of Post Partum Hæmorrhage.

Lawson Tait, F.R.C.S. Obscure Effects of Tertiary Syphilis.

J. G. Davey, M.D. Jenner and his Teachings.

Dr. Merrifield, Ph.D. The Meteorology of Plymouth for the last six years.

Cornelius Fox, M.D. The Estimation of Atmospheric Ozone by means of Aspirators and Acids.

J. W. Eastwood, M.D. Alcohol in Health and Disease.

R. Elliot, M.D. Life-Insurance Offices and Medical Fees.

William Ogle, M.D. Medical Reform personal, not parliamentary.

V. Jagielski, M.D. Koumiss: a Dietetic Remedy.

T. Clifford Allbutt, M.D. The Lesions of Enteric Fever as the Occasional Cause of a Permanent Injury to Nutrition.

C. B. Nankivell, M.D. The Provision of Medical Attendance on Independent Poor by Provident Dispensaries.

Arthur Ransome, M.D. The Respiratory Movements in Health and Disease.

D. T. T. Maunsell, M.B. Poor-law Medical Relief.

Gentlemen desirous of reading papers, cases, or other communications, are requested to forward the titles to the General Secretary, or to one of the Secretaries of the Sections in which the paper is to be read. All papers should be forwarded to one of the above named officers on or before the 1st of August.

No paper must exceed twenty minutes in reading; and all subsequent speakers must not exceed ten minutes.

All speeches at the General Meeting must not exceed ten minutes each.

T. WATKIN WILLIAMS, F.R.C.S., General Secretary.

13, Newhall Street, Birmingham, July 15th, 1871.

## THE PROPOSED ALTERATIONS IN THE LAWS.

In order that the members of the Association may be enabled to perceive the bearings of the alterations in the laws proposed by the Committee of Council, we subjoin in parallel two columns the laws as they now exist, and as they will appear if altered in the way proposed.

## PRESENT LAWS.

## LAWS WITH THE PROPOSED ALTERATIONS.

4. *Council and Officers.*—The Association shall be governed by a Council. The officers of the Association shall be: 1. A President; 2. Vice-Presidents; 3. President of the Council; 4. Treasurer; 5. Secretary.

6. *Vice-Presidents.*—The Vice-Presidents of the Association, who have been appointed after fulfilling the office of President, shall continue to enjoy the office for life; and the office of Vice-President shall be hereafter conferred, as an honorary distinction for life, on the retiring President, by a vote of the Members at the Annual Meeting.

7. *Council.*—The Council shall consist of the President, the President-elect, the President of Council, the Treasurer, and the Secretary of the Association, together with those members who shall be elected annually, according to Law 8. Its meetings shall be held at the time and place of the Annual Meeting, and at other times and places, if summoned by the President of the Council, or by the Committee of Council, or by a requisition signed by twenty members of Council.

8. *Election and Duties of Council.*—Each District Branch shall, in such manner as they think fit, before the General Annual Meeting, elect members who shall represent the Branch in the Council for the ensuing year, according to the following scheme: In a Branch consisting of not less than twenty members, one member shall be elected as representative, in addition to the Honorary Secretary. If the members amount to more than twenty, for every number of twenty additional members, each Branch shall be entitled to choose one additional representative. A complete list of the Members thus chosen shall be sent to the Secretary at least a fortnight before the Annual Meeting, and they shall continue in office till the close of the official year, when they may be either re-appointed or superseded. The duties of the Council shall be: 1. To agree upon a Report to be presented to the Annual General Meeting of the Association; 2. To nominate a President, to be submitted for election to the Annual Meeting; 3. To elect by voting papers ten members of the Council, who, together with the President of the Association for the year, the Vice-Presidents, the President-elect, the President of Council, the Treasurer, the Secretary of the Association, and one Secretary from

4. *Council and Officers.*—The Association shall be governed by a Council. The officers of the Association shall be: 1. A President; 2. A President-elect; 3. Vice-Presidents; 4. President of the Council; 5. Treasurer.

6. *Vice-Presidents.*—Each retiring President of the Association and President of Council shall be appointed a Vice-President for life, by a vote of the Members at the Annual Meeting.

7. *Council.*—The Council shall consist of the President, the President-elect, the Vice-Presidents, the President of the Council, and the Treasurer, together with those members who shall be elected annually, according to Law 8. Its meetings shall be held at the time and place of the Annual Meeting, and at other times and places, if summoned by the President of the Council, or by the Committee of Council, or by a requisition signed by twenty members of Council.

8. *Election and Duties of Council.*—Each Branch shall, in such manner as they think fit, before the General Annual Meeting, elect members who shall represent the Branch in the Council for the ensuing year, according to the following scheme: In a Branch consisting of not less than twenty members, one member shall be elected as representative, in addition to the Honorary Secretary. If the members amount to more than twenty, for every number of twenty additional members, each Branch shall be entitled to choose one additional representative. A complete list of the Members thus chosen shall be sent to the Secretary at least a fortnight before the Annual meeting, and they shall continue in office till the close of the official year, when they may be either re-appointed or superseded. The duties of the Council shall be: 1. To agree upon a Report to be presented to the Annual General Meeting of the Association; 2. To nominate a President, to be submitted for election to the Annual Meeting; 3. To elect by voting papers ten members of the Council, who, together with the President of the Association for the year, Vice-Presidents, the President-elect, the President of Council, the Treasurer, and one Secretary from each Branch, shall constitute the

Committee of Council for the ensuing year; 4. To propose the place of meeting of the Association for the ensuing year; 5. To nominate gentlemen to read such addresses as may be deemed expedient at the Annual Meeting of the ensuing year; 6. To determine the order of business of the General Meeting, so far as that is not determined by the laws relating to General Meetings.

9. *President of the Council.*—The President of the Council shall be, in the first instance, Sir C. Hastings, permanently; and on any vacancy occurring, the President shall be elected by the Council, at the Annual Meeting, for a term of three years.

10. *Treasurer.*—The Treasurer shall be, in the first instance, Sir Charles Hastings, permanently; and on any vacancy occurring, the Treasurer shall be elected at a General Meeting of the Association, and shall hold his office during pleasure.

11. *Secretary.*—There shall be one paid Secretary, resident in some convenient locality, so as to communicate readily with the President of the Council and the Committee of Council. His duties shall be to be present at the meetings of the Association, of the Council, and of the Committee of Council; to record their minutes; to conduct the correspondence of the Association; to superintend the collection of subscriptions, and the enforcement of the laws as regards those in arrear; and otherwise to obey the directions of the Council and Committee of Council. The Secretary shall be elected at an Annual or Special Meeting of the Association. The offices of Secretary and Editor of the JOURNAL shall not be held by the same person.

13. *Committee of Council.*—The Committee of Council shall manage the affairs of the Association in the intervals between the General Meetings; they shall meet not less than twice in the year, and shall be presided over by the President of the Council; or, in his absence, by a Chairman appointed by the Meeting. The Committee of Council shall appoint the Editor of the JOURNAL, who shall be responsible to them for its management: they shall direct any other publications of the Association, and shall take cognisance of any matter which may require immediate decision. Five members to be a quorum. The Secretary shall call a meeting of the Committee at any time on receiving a requisition from five of its members, the object for which the meeting is called being specified.

stitute the Committee of Council for the ensuing year;\* 4. To propose the place of meeting of the Association for the ensuing year; 5. To nominate gentlemen to read such addresses as may be deemed expedient at the Annual Meeting of the ensuing year; 6. To determine the order of business of the General Meeting, so far as that is not determined by the laws relating to General Meetings.

9. *President of the Council.*—The President of the Council shall be elected by the Council, at the Annual Meeting, for a term of three years.

10. *Treasurer.*—The Treasurer shall be elected at a General Meeting of the Association, and shall hold his office during pleasure.

11. *Secretary.*—There shall be one paid Secretary, who shall reside in London and devote his whole time to the business management of the Association and the JOURNAL Office. His duties shall be to be present at the meetings of the Association, of the Council, and of the Committee of Council; to record their minutes; to conduct the correspondence of the Association; to superintend the collection of subscriptions, and the enforcement of the laws as regards those in arrear; and to obey the directions of the Council and Committee of Council. The Secretary shall be elected at each Annual Meeting of the Association. The offices of Secretary and Editor of the JOURNAL shall not be held by the same person.

13. *Committee of Council.*—The Committee of Council shall manage the affairs of the Association in the intervals between the General Meetings; they shall meet not less than twice in the year, and shall be presided over by the President of the Council; or, in his absence, by a Chairman appointed by the Meeting. The Committee of Council shall appoint the Editor of the JOURNAL, who shall be responsible to them for its management: they shall direct any other publications of the Association, and shall take cognisance of any matter which may require immediate decision. Five members to be a quorum. The President of Council shall direct a meeting of the Committee to be called at any time on receiving a requisition from five of its members, the object for which the meeting is called being specified.

\* In this section, Dr. Wade proposes to alter "ten members" to "twenty-five" members, and to omit the Secretaries of Branches. Dr. Steele's notice of motion (see p. 132) must also be read in connection with this section.

14. *Admission of Members.*—Any qualified medical practitioner, not disqualified by any bye-law, who shall be recommended as eligible by any *three* members, shall be admitted a member at any time by the Committee of Council, or by the Council of any Branch; provided he shall have the Votes of three-fourths of those present.

15. *Subscription.*—The Subscription to the Association shall be One Guinea annually; and each member on paying his subscription shall be entitled to receive the publications of the Association for the current year. The subscription shall date from the 1st January in each year, and shall be considered as due unless notice of withdrawal be given in writing to the Secretary, on or before the 1st of December previous. If any member's subscription remain unpaid twelve months after it shall have become due, the publications of the Society shall be withheld from such member until his arrears be paid.

16. The name of no member shall remain on the books of the Association, whose arrears extend over three years; but the omission of the name from the list of members shall not be deemed, either in honour or equity, to relieve any member from his liability for the subscriptions due for the period during which he has availed himself of the privileges of membership.

24. *Publications.*—The Journal under the title of the "BRITISH MEDICAL JOURNAL: BEING THE JOURNAL OF THE BRITISH MEDICAL ASSOCIATION", shall be published weekly in London, and shall be conducted by a paid Editor, who shall be responsible for all that appears in its pages, except such matter as may be printed by direction of the Council or Committee of Council. The JOURNAL shall contain papers on medical science; and shall be considered the medium of communication between the members of the Association. In it shall be inserted all intimations of places and times of meetings, whether of the Association or the Branches; notices of motions, etc.; at least once in each year a list of the members of the Association; and any other Association business that the Council or Committee of Council may direct. *Transactions* shall be published occasionally, if the funds of the Association permit.

14. *Admission of Members.*—Any qualified medical practitioner, not disqualified by any bye-law, who shall express his desire in writing and shall be recommended as eligible by any *three* members, shall be admitted a member at any time by the Committee of Council, or by the Council of any Branch; provided he shall have the Votes of three-fourths of those present.

15. *Subscription.*—The Subscription to the Association shall be One Guinea annually; and each member on paying his subscription shall be entitled to receive the publications of the Association for the current year. The subscription shall date from the 1st January in each year, and shall be considered as due unless notice of withdrawal be given in writing to the Secretary, on or before the 1st of December previous. If any member's subscription remain unpaid twelve months after it shall have become due, the publications of the Society shall be withheld from such member so long as his subscription remains unpaid, provided due notice shall have been given of such withholding. Members may be admitted on and after July 1st in each year; and the subscription for such part of a year shall be half a guinea.

16. The name of no member shall remain on the books of the Association whose arrears extend over three years;\* but the omission of the name from the list of members shall not be deemed, either in honour or equity, to relieve any member from his liabilities to the Association.

24. *Publications.*—The Journal under the title of the "BRITISH MEDICAL JOURNAL: BEING THE JOURNAL OF THE BRITISH MEDICAL ASSOCIATION", shall be published weekly in London, and shall be conducted by a paid Editor, who shall be responsible for all that appears in its pages, except such matter as may be printed by direction of the Council or Committee of Council. The JOURNAL shall contain papers on medical science; and shall be considered the medium of communication between the members of the Association. In it shall be inserted all intimations of places and times of meetings, whether of the Association or the Branches; notices of motions, etc.; at least once in each year a list of the members of the Association and a copy of the Laws; and any other Association business that the Council or Committee of Council may direct. *Transactions* shall be published occasionally, if the funds of the Association permit.

25. *District Branches.*—For the purposes of self-government, and for the wider diffusion of the benefits of the Association, the members shall be united into District Branches. Any number of members meeting together may form themselves into a Branch of the Association; but no Branch consisting of less than *twenty* members shall have the privilege of sending a representative to the Council.

26. The District Branches shall be free to govern themselves as their respective members shall think fit; but no Branch Law shall be valid which in the opinion of the Committee of Council shall contravene any fundamental law of the Association.

27. The District Branches shall each pay their own expenses.

25. *Branches.*—For the purposes of self-government, and for wider diffusion of the benefits of the Association, the members shall be united into Branches. Any number of members meeting together may form themselves into a Branch of the Association; but no Branch consisting of less than *twenty* members shall have the privilege of sending a representative to the Council.

26. The Branches shall be free to govern themselves as their respective members shall think fit; but no Branch Law shall be valid which in the opinion of the Committee of Council shall contravene any fundamental law of the Association.

27. The Branches shall each pay their own expenses.

#### COMMITTEE ON PARLIAMENTARY BILLS.

At a meeting of the Parliamentary Bills Committee of the British Medical Association held on Wednesday, July 19th, at 37, Soho Square, Mr. Corrance, M.P., attended and explained the scope and purpose of his motion on Poor-law Reform; and the following resolutions were unanimously passed.

It was moved by Dr. STEWART, and seconded by Mr. CURGENVEN—"That this Committee, having heard Mr. Corrance's statement on the subject of medical relief to the poor through the dispensary system, similar to that carried out in Ireland, provided the distribution of tickets for medical attendance be restricted to the relieving officers, subject to confirmation by the guardians at their next meeting, are of opinion that his proposed measure will be beneficial to the poor, the ratepayers, and the public."

Proposed by Mr. CURGENVEN, and seconded by Dr. STEWART—"That the Parliamentary Committee, having considered the Local Government Bill, are of opinion that the measure is calculated to add greatly to the facilities for carrying out the various Acts relating to public health; and that they most cordially approve of the Bill."

Moved by Mr. ERNEST HART, seconded by Mr. CURGENVEN—"That this Committee, having considered the Lunacy Regulation Bill for Ireland introduced by Sir Dominic Corrigan, fully approve of the terms of the Bill; and that the Secretary be instructed to communicate with Sir Dominic Corrigan, in order to take steps to aid in passing this measure."

A Subcommittee was appointed to consider the amendments of the Pharmacy Bill, and also to draw up certain regulations which it was considered desirable to introduce into the Bill.

#### WEST SOMERSET BRANCH: ANNUAL MEETING.

The annual meeting of this Branch was held at the Royal Clarence Hotel, Bridgwater, on Tuesday, July 4th, 1871; W. H. AXFORD, Esq., M.B., in the Chair. There were present ten members and one visitor.

Mr. CORNWALL, the retiring President, after some remarks on his past year of office, introduced the President-elect, Mr. W. H. Axford.

Mr. AXFORD proposed a vote of thanks to Mr. Cornwall for the efficient and hearty manner in which he had performed his duties. The vote was carried by acclamation.

The Secretary laid before the meeting the replies he had received to his circular notice of the meeting, and remarked that twenty members had not answered it. The Minutes of the last annual meeting and of the special meeting held on April 29th last, were read and confirmed.

*Report of Council.*—The following report was read by the Secretary.

1. The Council are pleased in reporting that the Branch is in a very satisfactory condition, and that, as regards the number of members, it compares favourably with former years. There are now fifty names on the list; but it is hoped that a number of our medical brethren in the district, who are not yet members, may be induced to join the Association.

2. The accounts which will be presented show that a balance of £6:12:6 is in the hands of the Treasurer, to the credit of the Branch, after paying all expenses.

\* Mr. Nicholson proposes to substitute the word "two" for "three".

3. Two very interesting meetings have been held—one in October at Bridgwater, the other in March at Taunton—besides the annual meeting at Weston-super-Mare. At the latter the members were invited by Dr. Horace Swete and Mr. Charles Pooley to the Sanatorium, where they were most hospitably received and entertained. After inspecting that establishment and the Infirmary, they visited other places of interest, thus spending a very pleasant day.

4. A special meeting of the Branch was held on April 29th, to take into consideration the sending a member to represent the Branch in the Parliamentary Bills Committee of the British Medical Association. The number of members who attended being only five, and divided in opinion, no election took place.

5. A movement has been made at Bridgwater and other places for the purpose of instituting "Provident Dispensaries" which your Council thinks deserving of encouragement and support, as being calculated to make the lower orders more independent, and also to prove remunerative to the profession.

6. At a meeting of the Council on June 10th, held at Taunton, it was proposed by Dr. Cordwent, and seconded by Mr. Gillett, and resolved—"That the Council suggests, at the next general meeting, the desirability of the following mode of obtaining from each member of the Branch his opinion, and, to this extent, authority, on special points of interest; and that Dr. Kelly, the Honorary Secretary, be asked to kindly enclose with each announcement of a general meeting of the Branch a question on a medical or allied subject proposed by the Council, on which each member will be expected to express his opinion; but, having regard to the number of opinions sought to elicit, no argument in supporting an opinion shall exceed three minutes in delivering, whether read by the writer, or deputed, or spoken extemporaneously. Should the opinion on a question appear not to require support by argument, an affirmative or negative answer will, of course, be sufficient."

A discussion on the last (No. 6) paragraph having taken place, it was moved by Mr. W. H. AXFORD, seconded by Mr. WINTERBOTHAM, and resolved—"That the following words be added before 'enclose with each announcement,' etc.; viz., 'Send at least one month before, and enclose with each announcement,' etc.; and that the words 'five minutes,' etc., be substituted for 'three minutes,' etc."

The Report, as amended, was then received and adopted.

It was moved by Mr. RIGDEN, seconded by Dr. BENT, and resolved—"That the best thanks of the meeting be given to the Council for their Report, and for their services during the past year."

*The Treasurer's Report and Accounts*, audited by Mr. Robinson, were laid before the meeting; and on the motion of Mr. W. H. AXFORD, seconded by Mr. CORNWALL, thanks were voted to him for the same.

*Council*.—It was proposed by Mr. LIDDON, seconded by Dr. KELLY, and carried unanimously—"That Mr. Alford, Mr. S. Farrant, and Dr. Farmer be members of Council in the places of Mr. Randolph, Mr. Liddon, and Dr. Cordwent, who go out by rotation."

It was proposed by Mr. ROBINSON, seconded by Mr. CORNWALL, and resolved—"That the representatives of the Branch in the General Council for the ensuing year be Mr. W. H. Axford and Mr. Winterbotham."

Dr. Kelly was re-elected Secretary and Treasurer.

*Next Annual Meeting: President-elect*.—A letter from Mr. Garland, of Yeovil, dated July 3rd, 1871, was read; and a discussion on the suggestion made in his letter of holding some of the meetings nearer Yeovil having taken place, it was proposed by Mr. CORNWALL, seconded by Mr. ROBINSON, and resolved—"That the next annual meeting of the Branch be held at Langport, and that Mr. E. C. Garland be President-elect."

*Intermediate Meetings*.—It was proposed by Dr. BENT, seconded by Mr. WINTERBOTHAM, and resolved—"That intermediate autumnal and spring meetings be held as usual under the direction of the Council."

*Papers, etc.*—The PRESIDENT (Mr. W. H. Axford) read a carefully prepared paper on Vaccination. After referring to the prevalence of small-pox at the present time, as a reason for choosing vaccination as the subject of his address, the author referred to the probability that vaccination was known in very ancient times. He gave a quotation from an old Indian physician, which in his opinion referred to the operation. After briefly touching on Jenner's labours, he passed on to consider whether vaccinia and variola were one and the same disease. Various extracts and experiments were quoted to show that vaccinia is really identical with variola, but deprived of the "accidents" which, as Jenner held, have in the lapse of time become connected with it in the human subject, and which alone render it dangerous. In speaking of vaccination, the author strongly recommended the mixing of glycerine with the vaccine lymph in cases where there is a short supply, and also

where points on which lymph has been allowed to dry, have to be used. Lymph diluted with seven or eight parts of glycerine, he said, is perfectly efficacious. He also spoke of vaccinating with the scab which has fallen off an old vesicle, recommending it on the ground of the ease with which the active principle can thus be preserved unimpaired for years. In connection with the subject of the dilution of the lymph, it was shown that the leucocytes and the liquid portion of the lymph were inert, but that the granules which, with the leucocytes, are visible under the microscope, contain the active principle. The constitutional effects of vaccination were discussed, and the author then passed on to the good which it has effected, dwelling on the fact that it is not from the failure of vaccination, but from the inefficient performance of vaccination and of revaccination that small-pox has not entirely disappeared. He expressed his belief that, although a primary vaccination was most effectual, if not in all cases entirely to protect from the contagion, yet considerably to modify the disease; yet, from the changes which occur in the system at puberty, revaccination should after this period be always performed. No Vaccination Act could be perfect which did not render such revaccination compulsory. The wearing out of the effects of vaccination, from lapse of time, he considered not to be proved, believing the necessity for revaccination to be due entirely to the disturbing influence of puberty. The circumstances which influence the protective power of vaccination were considered under the four heads of Quality of the Vaccination; Age of the Person; Personal, hereditary, or family susceptibility; and Change of Climate. Under the first head the production of at least four perfect vesicles was insisted on; statistics shewing that, whilst the deaths in persons with only one cicatrix were 7.73 per cent., of those with four cicatrices only 0.55 per cent. of those attacked died. The author then went over the various objections which had been urged against the operation; and, in conclusion, briefly referred to the various Vaccination Acts. He disapproved of the present arrangements by which only one public vaccinator is appointed to a district, and warmly advocated that all registered medical practitioners should be able to obtain payment from the State for all successful vaccinations and revaccinations, and that such vaccinations and revaccinations should be compulsory.

Mr. RIGDEN read a short paper on two cases of Loose Cartilages in the Knee-joint operated on at the Taunton and Somerset Hospital by Mr. H. J. Alford, and exhibited the cartilages.

Several microscopes and interesting prints, photographs, and Mr. Haviland's Map of Heart-Disease, etc., were arranged by the President for inspection.

*Dinner*.—Nine members of the Branch and two visitors sat down to an excellent dinner at half-past five o'clock, and afterwards spent a very pleasant evening together.

## SOUTH WALES AND MONMOUTHSHIRE BRANCH.

The first anniversary meeting of this Branch was held at the Swansea Hospital on the 5th instant; GEORGE PADLEY, Esq., President, in the Chair. Between thirty-five and forty members were present.

The PRESIDENT opened the proceedings by bidding all present—on behalf of the profession—a hearty welcome to Swansea. He was happy to see them assembled in such numbers at the first annual meeting, and thought it augured well for the success of the Society.

*Report*.—Mr. ANDREW DAVIES, one of the secretaries, read the Report of Council, which dwelt upon the success of the Branch so far, there being ninety members, and ten fresh nominations.

Mr. J. G. HALL moved, and Mr. T. D. GRIFFITHS seconded, the adoption of the report, and of the recommendation of the Council as to the following modification of the second rule. "Any gentleman wishing to join the Branch shall be nominated by three members—such nomination to be forwarded to one of the honorary secretaries. The circular announcing the meeting next ensuing, provided it does not occur within twenty-one days of the receipt of such communication, shall contain the names and addresses of such candidate and his nominators, and shall be distributed not less than fourteen days before the date of such meeting. If no notice, etc."

*Officers, etc.*—It was resolved, on the motion of Mr. WATHEN, seconded by Mr. PROBERT, that the President, Council, and Secretaries elected at the inaugural meeting in January last be re-elected for the current year.

Mr. RUSSELL proposed as President-elect, T. J. Dyke, Esq., of Merthyr Tydfil. Mr. Dyke was a gentleman holding a very high professional position in the county, whose scientific attainments were well known, and who, he felt sure, would fulfil the duties of his office most ably.

Dr. YELLOWLEES seconded the motion, and it was carried unanimously.

Mr. DYKE briefly returned thanks.

*Representatives in the General Council.*—The following were elected:—T. J. Dyke, Esq., Merthyr; J. G. Hall, Esq., Swansea; W. Taylor, M.D., Cardiff; Dr. Yellowlees, M.D., Bridgend; Andrew Davies, Esq., Honorary Secretary, *ex officio*.

*Address.*—The President gave an address on Habitual Drunkenness, and the means to be taken to remedy it.

On the motion of Mr. RUSSELL, a cordial vote of thanks was passed to the President for his excellent address.

*Papers, &c.*—Some interesting papers were then read.

1. Mr. T. D. GRIFFITHS described a case of Wounded Intestines. The action of the longitudinal and circular muscular fibres was explained, and the conclusion was arrived at that it was unnecessary to apply sutures in cases of wounded intestines where the wound was small, unless the wound were in such a direction as to divide both sets of fibres.

2. Dr. WILLIAMS of Swansea showed specimens of a Vegetable Parasite attacking the Whiskers, and giving each hair the resemblance of having small nits upon it at equal distances. It was first described by Dr. Tilbury Fox about two years ago.

3. Dr. WILLIAMS showed a specimen of Aneurism of the Aorta. The third and fourth ribs were absorbed. In the process of dissection a valve was detected in the external carotid artery.

4. A case was shown by Mr. HALL (Swansea) of extraordinary Hypertrophy of the Skin of the Thigh and Leg as far as the ankle. It was said to disappear entirely after three or four months' rest in bed.

5. Mr. T. D. GRIFFITHS showed a case of Rodent Ulcer of the Lower Eyelid, to remedy which, after removing the diseased parts, he had removed the healthy eye, and closed the space by bringing down the upper eyelid and uniting it to the cheek.

6. Mr. HALL showed a case of Skin-grafting; and a case of Popliteal Aneurism cured by pressure.

7. Mr. GRIFFITHS showed a case of Rickets in a boy aged 15, first showing itself at the age of 13. The boy was a collier.

8. Mr. WATHEN read notes of a case of Puncture of the Colon to relieve Tympanitis. He also showed a new Starched Bandage Scissors, and a convenient method of fastening leather splints.

9. A paper by Mr. BROWN (Haverfordwest), on Death from Chloroform, was read by Mr. A. DAVIES.

10. Dr. YELLOWLEES read some practical notes on the Treatment of Insanity in Private Houses.

11. Mr. LLOYD read notes of a case of Ruptured Bladder, and showed the specimen.

*Dinner.*—In the evening, the members dined together at the Mackworth Hotel. The President occupied the Chair, and Mr. A. Davies, Secretary, the Vice-chair.

## REPORTS OF SOCIETIES.

### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, JUNE 27TH, 1871.

T. B. COELING, Esq., F.R.S., PRESIDENT, IN THE CHAIR.

THE Report from the Committee appointed to examine Mr. Hutchinson's cases of Vaccino-Syphilis was read.

ON DEXTAL PRE-EMINENCE. BY WILLIAM OGLE, M.D.

After a brief account of the chief explanations which have been given of right-handedness, the author advanced numerous arguments against the most generally accepted doctrine that it is based solely on conventional agreement, enforced by educational influence, and not on a natural foundation. Among these arguments were the following. The preferential use of one side is not limited to the arm, but extends to the leg, which is not subjected to education as the arm. The tendency to use one side preferentially manifests itself before education begins, and often persists in spite of the efforts made to overcome it. Left-handedness resembles many physical malformations in being hereditary, in running in families, and in attaching itself rather to the male sex than to the female. Men are not the only animals with a tendency to use one side preferentially; the author had observed the same tendency in monkeys and in parrots. There must hence be some structural foundation for right-handedness. In right-handed persons the left hemisphere is pre-eminent over the right; and in left-handed persons the left hemisphere has a similar superiority. This latter statement, the probability of which was suggested by Dr. OGLE several years ago

(*St. George's Hospital Reports*, vol. ii, 1867), was supported by three cases of aphasia in left-handed persons, accompanied by left hemiplegia, which the author had himself seen, and a fourth recorded by Dr. Jackson. Hence right and left-handedness would seem to depend on a natural predominance of the left and of the right hemispheres respectively. The author stated that, while the left hemisphere is the more complex in right-handed persons, and the right in left-handed individuals. This latter statement was based on the examination of the brain in two left-handed subjects. The specimens and also tracings of them by Dr. Broadbent were exhibited. The greater development, as a rule, of the left hemisphere depended probably, it was argued, on the left hemisphere receiving a freer supply of blood than the right one. The results of the author's observations as to the relative sizes of the arteries on the two sides of the neck were given; from which it appeared that the left arteries are, as a rule, slightly larger than the right ones; and that, independently of the size of the vessels, the stream of blood is less hindered on the left side than on the right. Lastly, it was stated that this explanation was consistent with, and corroborated by, the peculiarities of the cerebral blood-supply in those other animals which, like man, manifest a tendency to use one side preferentially to the other.

ON THE INDICATIONS FOR OPERATIVE TREATMENT, AND ON A NEW OPERATION, "KERATECTOMY," AFTER SEVERE INJURIES OF THE EYEBALL; WITH CASES. BY W. SPENCER WATSON, F.R.C.S.

In the case of penetrating wounds, the occurrence of glaucomatous symptoms was stated to be the most urgent indication for operative treatment—viz., either linear extraction, or iridectomy. At a later stage, after the subsidence of the acute symptoms, iridectomy might be required, or the removal of the cataract indicated; and these operations were most likely to be successful after the disappearance of all signs of active congestion. Cases in illustration were given. The prospect of the complication of sympathetic ophthalmia was always possible when the stage of congestion, with pain and photophobia, was much prolonged, and whenever a foreign body was left in the injured eye. In these circumstances, the removal of the injured eye was sometimes necessary; but if constitutional treatment could be properly carried out, the removal of the injured eye might be postponed or altogether averted. A case in illustration was given. In traumatic and idiopathic cases of suppurative ophthalmitis the operation of keratectomy was proposed; in one case it had been performed successfully by Mr. Watson. Its object was to establish a fistulous opening in the cornea, through which the morbid products of the inflammation might escape. It was suggested that in some cases of threatened suppurative ophthalmitis, keratectomy might prevent the anticipated mischief.

MODIFICATIONS PRODUCED ON THE TEMPERATURE OF THE BODY BY THE LOCAL APPLICATION OF COLD AND HEAT.

BY FREDERICK BARHAM NUNNELEY, M.D.

Experiments detailed in the paper had yielded the following results. 1. Immersion of one extremity in iced water did not cause any alteration in the temperature of the other extremities or the body generally, unless the subject of experiment were in a state of more or less nervous exhaustion or there were decided coolness of the surrounding air, when a fall of temperature occurred. 2. A slight rise of temperature in the body generally, and a more considerable one in the extremities, followed immersion of a hand or foot in water hotter than the blood, amounting under the tongue to about one deg. Fahr., and in the extremities from one to three deg. Fahr., above the normal standard. 3. If at this time any one of the extremities were put into cold water, a fall of temperature below the normal, slightly marked in the body generally, and much more so in the extremities, very shortly commenced. If the hand or foot were now withdrawn from the water, reaction became established, and the natural temperature was slowly attained. Such results would appear to show that, for cold to act locally, a disturbance of the conditions which maintain the normal balance of temperature was necessary first of all—such as might be caused by undue heat; and they suggested the idea that these variations of temperature be regarded, in many respects, as parallel to those attending a slight rigor, and that they were not always the result of reflex agency.

A SIMPLE METHOD OF REMOVING SILVER WIRE WHEN EMPLOYED IN CASES OF UNUNITED FRACTURE. BY FRANCIS MASON, F.R.C.S.

The object of the paper was to describe a plan of fastening the broken fragments with a needle and a loop of wire so arranged that in withdrawing the needle the loop of wire was released, and thus might be removed without pain to the patient and without injuring the bone or soft parts.

At the conclusion of the meeting, the President drew the attention of the Fellows to the change in the times of assembling which had been

adopted, and which would commence with the next session—namely, that the first meeting of the Society would be on the second Tuesday in October instead of in November. He further mentioned that, to allow the alterations connected with the Society's meeting-room to be previously carried out, the library would be closed during the months of August and September.

## CORRESPONDENCE.

### BRITISH MEDICAL ASSOCIATION.

SIR,—The very great importance of some of the proposed changes in the laws of the Association which are to be submitted to the members assembled at the Annual Meeting at Plymouth next month, more especially of those relating to the General Secretary, makes me feel that it may be well for the Association, or, at the least, may much conduce to the dispatch of business on that occasion, if the members generally can be made acquainted *beforehand* with the circumstances which have led to these proposals being made; and with that view, I venture to send for publication the following observations on the subject, which (it is right I should not omit to say) I have not submitted to any other member of the Committee of Council, but merely offer for what they may be worth as the result of my individual acquaintance with the subject.

In my capacity as the local secretary of a large Branch, a knowledge of facts connected with the working of the Association gradually accumulated with me during the last two or three years, of a kind, and to such an extent, as to convince me that either reform or financial disaster must soon ensue. A representation of some of these to the Committee of Council last Autumn, induced them to appoint a Subcommittee on "the financial condition and organisation of the Association." That Subcommittee had two lengthened meetings, and matters of such gravity were there revealed, that the Committee of Council itself afterwards bodily took up the subject, and investigated it in all its bearings. Altogether, nearly the whole of five days were occupied thereby; and the following were some of the facts and conclusions arrived at.

1. That the General Secretary did not keep any minutes of the annual meetings.

2. That a number of important business-resolutions passed at the last Annual Meeting (at Newcastle) had not been acted upon at all by him; and that still more important business-resolutions of the Journal Committee had been either altogether omitted from the minute-book, or had been imperfectly and incorrectly acted upon.

3. That the General Secretary had not considered it his business to perform such duties (notwithstanding Law 11 of the Association).\*

4. That he had not acted on a resolution of the Journal Committee ordering that the "Clerk and Collector" at the office should find security; and that such officer having defaulted to the amount of several hundred pounds, and absconded, the loss would fall upon the Association.

5. That the General Secretary did not admit himself to be responsible for the business-management of the office (where a very large part of the financial business of the Association is being continually carried on); and that there was no one else who was so responsible. Consequently, that in the period intervening between March 1868 and October 1870, it had fallen into great confusion, which led to the subsequent loss, and to great annoyance to members.

6. That, owing to the Secretary being resident in the country, and the JOURNAL published in the metropolis, lists of the members had to be kept and corrected incessantly, according to changes, in two places at once; viz., Birmingham and London. That this entailed delay at all times, and often great delay, which multiplied correspondence, expense, errors, trouble, and annoyance to all persons concerned, including the Branch Secretaries and the members, and consequently injury to the Association generally. A mass of letters from members, full of complaints, was laid before the Committee, proving the above.

7. It transpired clearly at one of the first meetings, that the great mass of the large arrears of subscriptions existing at the beginning of this year lay amongst those members of the Association from whom it

was the special province of the General Secretary to collect them; and a subsequent examination and careful analysis of his books by Mr. Clayton of Birmingham, not only confirmed this to an astonishing extent, but also showed some very puzzling discrepancies to exist in some of his returns.

So great has the loss been from this source that, whereas among the members of large branches from whom the Honorary Local Secretaries collected, there were only from 3 to 8 per cent. of arrears for the year; amongst those (not members of Branches) from whom the paid General Secretary should collect, the arrears amounted to 30 and even 50 per cent.

Finally, the Committee, which I may state consisted, with one exception, of provincial members, came to the conclusion that it is essential for the well-being and doing of the Association that its business should be simplified and consolidated, and that the General Secretary should be formally and responsibly charged with the management of it; and to this end, they resolved (at a large meeting, and *nem. con.*) to recommend the members, at the Annual Meeting at Plymouth, to alter the laws so as to require the General Secretary to be a gentleman who shall reside in London, and who can devote his whole time to the duties. And this resolution, I have good reason to believe, the Committee of Council are extremely anxious, in the best interests of the Association and with the approval of the members, to carry out.

A notion expressed by some that this course will "unprovincialise" the Association, I have not the least apprehension of beyond what already is the case; for now it is neither *provincial* nor *metropolitan*, but *both*, or, rather, it is *national*; and national it must continue to be, if it continue at all.

I believe, sir, that once placed on a sound financial basis, and its business conducted properly, the Association will prosper rapidly, and soon so pervade the country that it will be exceptional for any respectable medical man not to be a member of it. The change of name from Provincial to British was, I believe, suggested by a provincial member—Mr. Trustram, of Tunbridge Wells; and, so far as I know, the metropolitan members have never manifested any desire to centralise the Association in London.

To conclude, I may express a conviction that, instead of the fact of the two officers (Editor and Secretary) both resident in London being likely to lead to difficulties, as has been suggested, it is likely to prove quite the reverse, as their positions and their duties will be perfectly distinct and independent of each other.

Apologising for the length of this communication, which duty and not pleasure has led me to make, I am, etc.,

Brighton, July 25th, 1871.

G. F. HODGSON,  
Honorary Secretary of the South Eastern Branch.

### FLEXIBLE PROBE.

SIR,—In drawing the attention of the profession to a flexible probe which I have lately devised, I do not for a moment dispute the question of priority with Dr. Sayre. His has been made many months before mine; but it is gratifying to feel that the necessity for such an instrument has been felt on both sides of the Atlantic at about the same time, and that instruments have been planned with the same object.

About two months ago I designed a very simple flexible probe, and requested Messrs. Maw, Son, and Thompson, of Aldersgate Street, to make it. About three weeks ago I received one fully carrying out my wishes, and was carefully testing its merits when my attention was drawn to a notice of Dr. Sayre's instrument. The requirements I perceived to be, an ordinary probe end connected to an ordinary probe handle by a perfectly pliable yet elastic metal stem. With this view I suggested the two extremities of an ordinary eyed probe to be connected together by silver suture-wire, coated with gum-elastic. The simple instrument so made I find to be thoroughly efficacious, very sensitive, and remarkably painless. It has not the advantage which Dr. Sayre's possesses, of being rendered stiff; but this in practice I do not find necessary, while it has the advantage of being cleaned as simply and quickly as any other probe. For examining bullets, a porcelain end may be affixed instead of the silver. I have one of the ordinary probe length, another about twice as long, but they may be made longer if needful: in fact, I have been wishing for a case of psoas abscess to try if I could not feel the carious lumbar vertebrae. The makers have applied a handle of small size on the plan of the handle of Sir H. Thompson's hollow sound, which may intensify sensibility.

I am, etc.,

CHARLES STEELE, F.R.C.S.

Clifton, July 22nd, 1871.

\* 11. There shall be one paid Secretary, resident in some convenient locality, so as to communicate readily with the President of the Council and the Committee of Council. His duties shall be to be present at the meetings of the Association, of the Council, and of the Committee of Council; to record their minutes; to conduct the correspondence of the Association; to superintend the collection of subscriptions, and the enforcement of the laws as regards those in arrear; and otherwise to obey the directions of the Council and Committee of Council. The Secretary shall be elected at an Annual or Special Meeting of the Association. The offices of Secretary and Editor of the JOURNAL shall not be held by the same person.

## OBITUARY.

JOSEPH G. LANSDOWN, F.R.C.S., BRISTOL.

JOSEPH GOODALE LANSDOWN was born at Bristol in 1804. He was educated at the Tiverton Grammar School, and was afterwards apprenticed to the late Mr. H. Daniel, Surgeon to the Bristol Royal Infirmary, at which institution he commenced his professional career. He then studied at St. Bartholomew's Hospital and the Aldersgate Street School; and obtained his diplomas in 1827 and 1828. After visiting the continental hospitals, he settled in Bristol, and was elected one of the first Surgeons to the Bristol General Hospital in 1832. This office he held until 1861, when he was appointed Honorary and Consulting Surgeon. He was a skilful operator, and one of the first to use anæsthetics in surgery, and in midwifery he used chloroform extensively. He was devoted to his profession, and worked unceasingly at a large practice, rarely taking a holiday. He made some short commentaries on anæsthesia in its early days to some of the journals; but his time was so fully occupied that he seldom put his thoughts on paper. He was obliged to retire from practice at the end of 1870, owing to the encroachments of a large thyroid tumour, which so compressed his trachea as ultimately, on July 6th, to cause his death. He was a man of genial disposition, beloved by a large circle of patients and friends.

## MEDICAL NEWS.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At an extraordinary meeting of the College, on Monday, July 24th, the following gentleman was duly admitted a member of the College.

Van, J. Burney, M.B. Lond., St. James's Street

The following gentlemen, having conformed to the by-laws and regulations, and passed the required examinations, were granted Licences to practise Physic, including therein the practice of Medicine, Surgery, and Midwifery.

Bayley, Robert L., M.D., 86, High Street, Stourbridge  
Cottle, Ernest W., B.A. Oxon., M.R.C.S., Southampton  
Curling, William, Guilford Street, Russell Square  
Dunlop, George Davidson, Castle Terrace, Newark  
Ellis, William Hodgson, M.B. Toronto, Toronto  
Evans, John Henry, M.R.C.S., Gipsy Hill  
Goldie, Eugene, M.R.C.S., Pentonville Road  
Lowe, Lewis, M.R.C.S., Argyll Square  
Lowe, John Allan, M.R.C.S., Middlesex Hospital  
Maize, Edward W., M.R.C.S., Grove Park, Chiswick  
Nodder, Samuel S., M.R.C.S., Charing Cross Hospital  
Parrott, Edward John, M.R.C.S., Buckland, near Tring  
Preston, Thomas, Stepney Green  
Russon, Frederick P. F., King's College Hospital  
Stoddard, Thomas, M.R.C.S., Ripley, Derby  
Waller, Walter A. E., M.R.C.S., Guy's Hospital  
Wentworth, Frederick, M.R.C.S., Putneybridge  
Yarrow, George E., M.D. Hotel, M.R.C.S., Old Street

The following candidates, having passed in Medicine and Midwifery, will receive the College Licence on their obtaining qualifications in Surgery recognised by the College.

Leitch, William W., St. George's Hospital  
Duke, Douglas W., Belvedere Place, Upper Norwood

At the ordinary quarterly meeting on July 27th, the following gentlemen, having passed the required examinations, were duly admitted as members.

Carter, William, M.B. Lond., Broadbent Street, Liverpool  
Cox, John, Assistant Lecturer, M.D. St. Andrew's, Warwick Street  
Fleming, Joseph William, M.D. Edin., Leamside Park, Darlington  
Foster, George, Henry, M.D. Camb., The Prince's Hospital  
May, Samuel, Bedford Place, Russell Square

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at a meeting of the Court of Examiners, on July 25th.

Barnes, Frank Edward, Westminster Central (Guy's)  
Barnes, Thomas Hughes, Chancery Lane (Guy's)  
Bryant, Francis Thomas, Northampton (St. Mary's)  
Caldwell, Francis, Great Marlborough Street (St. George's)  
Clarke, Frederick Henry, Devonport (Guy's)  
Coomes, Frederick, Kew, North Wales (Charing Cross)  
Coomes, William, Kensington (Guy's)  
Dunlop, Edward James, Exeter (Guy's)  
Edwards, William, F. Street, Gloucester (Guy's College)  
Evans, Robert William, Surgeon to the West Birmingham Railway  
Finn, John Robert, Pinner, Middlesex  
Fitz-James, William, Tring, Herts (Guy's College)  
Graham, F. Street, London (St. John's Hospital)  
Hoggins, Wm. Harris, West Medford, Northamptonshire (University College)

Holden, Alfred Fletcher, Cape of Good Hope (University College)  
Hopkins, Frederick Fraser, Henley-in-Arden (Birmingham School)  
Hughes, Evan Thomas, Kirkby Stephen, Westmorland (Glasgow School)  
Hughes, Hugh Robert Greig, Bangor, North Wales (Edinburgh School)  
Hutson, Charles, Barbadoes (St. Bartholomew's)  
Johnson, Charles Hargitt, Hull (Guy's)  
Kiddle, John Nelson, Adelaide Road (Guy's)  
Lammiman, Cleland, Commercial Road (St. Bartholomew's)  
Ledyard, William Edward, Toronto, Canada (St. Thomas's)  
Lyons, Isidor Isaac, Alexandria Road, St. John's Wood (St. Bartholomew's)  
McDonald, Wallis, Teignmouth, Devon (St. George's)  
Smith, Gilbert, Blackrock, Co. Dublin (Dublin School)  
Southey, Henry Edward, Ely, Cambridgeshire (Guy's)  
Spencer, Francis Henry, Chippingham (King's College)  
Thurland, Francis Edward, Thurslaston, Cheshire (St. Bartholomew's)  
Walter, Clement Cuthbert, Dover (St. George's)  
Watson, William George, Sydney, Australia (University College)  
Willcocks, Isaac, West Looe, Cornwall (St. Bartholomew's)  
Williams, Edward, Aberbank, Llandysil (University College)  
Wybrants, Robert Bath, Shepton Mallett (Dublin School)  
Younger, Edward George, Blackheath Hill (Guy's)

Admitted members on July 26th.

Bishop, Edward Stanmore, Manchester (Manchester School)  
Briggs, George Chapman, Horncastle (King's College)  
Cheyne, George Edward, Thornton Heath (St. Bartholomew's)  
Clarke, John Clelland, Coleraine, Ireland (Edinburgh School)  
Fendick, Thomas Rowing, Mylne Street, Clerkenwell (St. Bartholomew's)  
Garton, William, St. Helens, Lancashire (St. Thomas's)  
Hugman, William, Guildford Street (St. Bartholomew's)  
Morison, Bentham Paynter, Portclew, Pembroke (Guy's)  
Newman, Ashwin Conway, Winchcombe, near Cheltenham (Guy's)  
Norman, Joseph Clement, Colchester (St. Bartholomew's)  
Pratt, Charles William, Plymouth (St. Mary's)  
Pye-Smith, Rutherford John, Hackney (Guy's)  
Read, Charles, Guildford Place, Russell Square (St. Bartholomew's)  
Reed, James, Stoke, Devonport (Guy's)  
Rogers, Charles Claude, Cork Street, Bond Street (Middlesex)  
Scully, John, Wimpole Street (Middlesex)

Ten candidates having failed in the two days' examination to acquit themselves to the satisfaction of the Court of Examiners, were referred to their hospital studies for six months.

Arts Examinations.—At the last preliminary examination of the Royal College of Surgeons, which was conducted by the College of Preceptors, 313 candidates presented themselves, viz., 82 for the preliminary examination for the fellowship, and 231 for the membership. Of the total number, 155 passed, viz., 100 for membership, and 55 for fellowship; 15 will have to be re-examined in some subjects, having previously passed examinations for membership; and 143 were altogether rejected.—The following gentlemen are reported to have passed for the fellowship, viz.:

Messrs. T. O. F. Alsop, W. H. Briggs, A. Boswell, W. H. Bull, B. Bubb, W. F. Boase, H. M. Baker, J. S. N. Boyd, E. Chambers, F. de B. Collette, W. E. Cant, R. T. P. Collins, C. A. Currie, E. J. D'Gruyther, T. Davies, T. D. F. Evans, S. H. Fisher, B. F. Giles, J. T. Graham, H. Green, H. B. Guppy, W. C. Haley, T. M. Howell, J. A. Kempe, P. Phelps, W. S. Johns, S. J. J. Kirby, G. T. Kellie, R. W. Leftwich, R. P. Musgrave, L. Mackenzie, A. S. Norman, C. H. Newby, W. Phelps, G. F. Poynder, C. F. Pickering, H. N. Pendleton, J. Scully, W. Stericker, T. Smith, C. J. W. Stocker, F. G. Stewart, W. A. Stephenson, A. L. Tate, W. H. White, R. B. Wilkins, R. F. Woodcock, and A. S. W. Young. The following gentlemen who entered for the membership examination reached the standard required for the fellowship, viz., Messrs. J. W. Allen, W. P. Blackley, J. M. Cotterill, H. T. A. B. Fellows, C. J. Ellam, M. H. H. Vernon, and W. H. Walker.

The following passed for membership, viz.:

Messrs. R. K. Archer, W. T. Angove, H. C. Allison, H. A. Angelo, de B. Birch, C. J. D. Astley, R. G. Batley, J. W. Bond, J. U. Bickers, A. H. Boys, P. Cree, E. Carcenac, H. E. F. Cross, H. Cane, W. Cock, S. D. Clippingdale, H. J. Capon, W. T. Davey, A. J. W. Pettigrew, E. R. Da Costa, R. Edmunds, C. E. Diggle, C. A. Danberry, H. W. Ewen, W. M. Evans, W. M. Frobrisher, F. Carter, F. B. Fisher, J. Greensill, J. Davies, J. F. Grayling, E. B. Holwell, G. H. Hornsby, F. G. Harvey, W. A. Hay, F. E. Henbeck, W. Hodgson, R. Harding, G. H. Jackson, T. Johnson, W. C. James, J. W. Lawton, G. H. Leach, G. Latham, E. S. Morgan, H. R. Mark, W. F. Mitchell, J. G. Moses, A. F. Maynard, W. G. H. B. Marsh, W. A. Muggs, J. W. O. Mogg, H. E. J. G. Miller, W. I. Mchelly, W. Norman, O. E. B. Marsh, F. J. Latham, H. W. James, A. F. Parker, W. C. Nicholls, F. C. Palmer, G. B. Rawen, A. P. Russell, J. Ryley, R. C. Reid, J. B. Sincok, A. J. Rowbotham, L. E. H. Shewell, A. Smart, H. Todd, E. O. Scallan, G. A. Tait, G. M. Tuke, J. Tuke, H. G. Thompson, J. T. Toll, H. Tidy, D. P. H. Taylor, G. Underhill, I. G. H. Whitley, A. G. Williams, G. A. Walker, R. C. S. Walcott, A. H. Wilson, A. H. Thompson, E. V. Whitley, E. I. Williams, F. S. Smyth, J. Carroll, C. R. Hall, H. A. Speed, J. J. F. Barnes, C. C. Reddons, A. L. Douglas, H. E. Friend, S. O. Hector, H. J. D. Innes, J. M. McCarthy, W. D. Stamp, and W. G. Guppy

There will not be another examination in Arts until December.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received their certificates to practise, on Thursday, July 20th, 1871.

Adam, Charles Edmund, 7, Clifton Place, W.  
Bullock, Alfred, Chatterhouse Square  
Briggs, Moses George, Welford, Northamptonshire  
Bryan, Francis Charles, Belmore Crescent  
Fosdick, George Haynes, Bedford, Redditch

Furner, Willoughby, King's Road, Brighton  
Harris, Michael, Hackney  
Tombs, George Augustus, Cirencester

The following gentlemen also on the same day passed their first professional examination.

Bosson, George, University College  
Brodrick, Charles Aikin, St. Mary's Hospital  
Brodrick, Francis Benjamin, St. Bartholomew's Hospital  
Brumwell, James Parker, Guy's Hospital  
Carey, Richard John, University College  
Davies, George Augustus, University College  
Lawton, Herbert Alfred, St. Thomas's Hospital  
Moxon, John, King's College  
Morgan, William Lewis, London Hospital  
Shapley, Harry Tom, London Hospital  
Webber, William Littleton, St. Bartholomew's Hospital

As an Assistant in compounding and dispensing medicines.

Bradley, John, Bingley, Yorkshire

### MEDICAL VACANCIES.

The following vacancies are announced:—

ABERFOYLE, Perthshire—Parochial Medical Officer.  
ATHLONE UNION, co. Westmeath—Medical Officer for the Moate Dispensary District.  
BIRMINGHAM and MIDLAND FREE HOSPITAL for SICK CHILDREN—Resident Medical Officer.  
BOURNEMOUTH GENERAL DISPENSARY—Resident Surgeon.  
BRIDGWATER UNION, Somersetshire—Medical Officer for District No. 7.  
BRADFORD (Yorkshire) INFIRMARY and DISPENSARY—Physician.  
DERBYSHIRE GENERAL INFIRMARY, Derby—Resident Assistant House-Surgeon; Two Dental Surgeons; Non-Resident Dispenser.  
HEREFORD GENERAL INFIRMARY—House-Surgeon.  
HOSPITAL FOR SICK CHILDREN, Great Ormond Street—Assistant-Physician.  
INFIRMARY for EPILEPSY and PARALYSIS, Charles Street, Portman Square—Physician.  
KINGTON UNION, Herefordshire—Medical Officer for the Eardisley District.  
LEEDS GENERAL INFIRMARY—Fourth Assistant Resident Medical Officer.  
LOUDOUN, Ayrshire—Medical Officer and Public Vaccinator.  
LOYAL EARL OF LONSDALE LODGE OF ODD FELLOWS, Bampton, Cumberland—Medical Attendant.  
NEUBURY UNION, Berks—Medical Officer for the Thatcham District.  
NEWCASTLE-ON-TYNE LYING-IN HOSPITAL—Visiting Surgeon for the Out-department.  
OLDBURY BOARD OF HEALTH—Medical Officer.  
SANDAY, Orkney, Island of—Medical Officer.  
SPANISH and PORTUGUESE JEWS LYING-IN INFIRMARY—Surgeon.  
UNST, Shetland—Parochial Medical Officer and Public Vaccinator.

### MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

BUCKLY, Daniel Francis, L.R.C.P. Edin., appointed Medical Officer for the Clane and Timahoe North Dispensary District of the Naas Union, co. Kildare.  
CATON, Richard, M.D., appointed Demonstrator of Practical Physiology and Histology at the Liverpool Royal Infirmary School of Medicine.  
EUSTACE, Robert, L.F.P.S. Glasg., appointed Medical Officer for Westray, Orkney.  
O'FLAHERTY, Jerome, Esq., appointed Medical Officer, etc., for Division No. 1 of the Kingstown Dispensary District of the Rathdown Union, co. Dublin.  
MACLELLAND, Alexander, M.B., appointed Medical Officer for Dailly, Ayrshire.  
REID, John Henry, L.R.C.P. Ed., appointed Medical Officer, etc., for the 2nd Division of the Kilkeel Dispensary District of the Kilkeel Union, co. Down.  
WATT, Dr. J. Ross, appointed Medical Officer for the District of Innellan, parish of Dunoon and Kilmun, Argyshire.  
WEIR, James B., M.B., appointed Medical Officer for the parish of Rerrick, Kirkcudbrightshire.  
WILSON, Henry, Esq., appointed Junior Surgeon to St. Mark's Ophthalmic Hospital, Dublin.

### BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication.

#### BIRTHS.

BLANDFORD.—On July 15th, at 71, Grosvenor Street, Grosvenor Square, the wife of \*G. Fielding Blandford, M.D., of a daughter.  
BOGGS.—On July 14th, at Paris, the wife of Alexander Boggs, M.D., late of Her Majesty's Indian Army, of a daughter.  
WRIGHT.—On July 8th, at Birmingham, the wife of \*M. Hall Wright, Esq., Surgeon, of a son.

#### MARRIAGE.

GOYDER, David, M.B., of Bradford, Yorkshire, son of the Rev. D. G. Goyder, of Wivenhoe, Essex, to Ann Eliza, second daughter of Robert THOMAS, Esq., of Rawdon, near Leeds, at St. Mary's, Moseley, near Birmingham, by the Rev. J. R. Davison, assisted by the Rev. R. B. Earé, on Thursday, July 20th. No cards.

#### DEATHS.

CRAWFORD, John Duncan, M.B., Surgeon-Major of the 2nd Bengal Cavalry, at Dhurmala, Punjab, India, on May 16th.  
DARLINGTON, Abraham E., Esq., Surgeon, at Prees, Shropshire, aged 74, lately.  
WHITELAW.—On July 17th, suddenly, at Kirkintilloch, N.B., aged 2 years, William Peter, second son of \*W. Whitelaw, M.D.

### OPERATION DAYS AT THE HOSPITALS.

MONDAY ..... Metropolitan Free, 2 P.M.—St. Mark's, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.  
TUESDAY ..... Guy's, 1.30 P.M.—Westminster, 2 P.M.—National Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.  
WEDNESDAY... St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.  
THURSDAY... St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.  
FRIDAY ..... Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic Hospital, 2 P.M.  
SATURDAY... St. Thomas's, 9.30 A.M.—St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Lock (Clinical Demonstrations and Operations), 1 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—East London Hospital for Children, 2 P.M.—Hospital for Women, 9.30 A.M.

### NOTICES TO CORRESPONDENTS.

ALL Letters and Communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen Street, Lincoln's Inn Fields, W.C.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

TO PURCHASERS.—To insure attention, it is requested that all orders sent to the Office for extra copies of the JOURNAL, be accompanied with halfpenny stamps for the amount.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

RAILWAY ARRANGEMENTS FOR THE ANNUAL MEETING.—A London member will find all the information that we possess regarding the railway arrangements for the annual meeting, in the programme published at page 131. We understand that up to the present date no diminution of fares has been agreed on by the Great Western Railway.

#### THE NAVY MEDICAL SERVICE.

SIR.—The Admiralty are again in the market and bidding for medical recruits. Yet they have just ordered the Staff Surgeon of the Flag Ship in the Flying Squadron (a not unimportant squadron now-a-days) to refund all the additional pay he has drawn as Staff Surgeon of a Flag Ship, viz., five shillings per diem, on the score that the Admiral in command who had sanctioned the issue of the sum is "Commanding-in-Chief," and not "Commander-in-Chief." To make this Act of injustice still more glaring, the Paymaster Navigating Officer and Chief Engineer all draw special allowances over and above their regular pay in virtue—mark this—of their being in a Flag Ship.

I am, etc., AN ASSOCIATE.

THE TREATMENT OF GANGLION.—Dr. G. Goddard Rogers writes to say that, during 1856, he often found difficulty in writing, owing to a painful ganglion connected with the extensor sheath of the right carpus. He used iodine freely, and kept up a succession of blisters. It so happened that, at the time, a paper was read at St. George's Hospital Medical Society which led to a discussion on the different forms of ganglion. He exhibited his, which every member present manipulated. Considerable pain followed, but in two or three days all trace of the ugly swelling was lost; and from that time to the present he has experienced no inconvenience.

ANOTHER member writes to say that, several years since, a large ganglion on the wrist, of considerable standing, was most effectually dispersed by a blow from Liddell and Scott's Lexicon.

#### DR. LEWIS SAYRE'S HIP-JOINT SPLINT.

MR. HOWARD MARSH, Surgeon of the Children's Hospital, writes to correct an error "in the otherwise excellent report" of Dr. Lewis Sayre's clinical reports, which appeared in the JOURNAL of last week. "The child who before had evinced extremely acute suffering on slight movement of the joint, as soon as the apparatus was applied was able to bear without pain free movement of the limb, and the rough shaking of the chair on which he sat." The case to which it was applied was not in the recent acute stage, and the limb, which was greatly flexed, could not at the time be so straightened as to allow the child to walk. In this latter particular, the report seems to have mixed up two cases. Mr. Marsh expresses a strong opinion of the value of the splint, which, as the case proved, "answered admirably the purpose of its inventor—to prevent concussion of the joint surfaces together on any movement of the limb." He proposes to give it a careful trial, and, we are pleased to add, to furnish our readers with the results which he obtains. We hope that other surgeons who, we believe, profess to try the splint, will also place their results before our members.

#### TREATMENT OF TAE-TOE-M.

SIR.—Other remedies having failed to cure tinea in M.D.'s case, antonine, which I have found answer in a similar case, or the pomegranate root bark, in powder or decoction, deserves a trial. Either remedy should be followed by a good dose of castor oil, or castor oil with turpentine. It would be interesting to know the result.

I am, etc.,

THOS. M'CLURE, L.R.C.P.

SIR.—I recommend M.D. to try Chabert's empyreumatic oil—two teaspoonfuls administered morning and evening for several days after an active purgative. As the oil is nauseous, it should be administered in a strong carminative mixture. The dose should be continued for some time with the interposition of repeated doses of an active purgative.

I am, etc.,

LEAMINGTON, July 18th, 1871. JAMES THOMPSON, M.D.

**NOTICE TO ADVERTISERS.**—Advertisements should be forwarded direct to the Printing-Office, 37, Great Queen Street, W.C., addressed to Mr. F. H. HEATHCOTE, not later than *Thursday*, twelve o'clock.

The document forwarded to us concerning the Walsall Cottage Hospital appears to be confidential; and we should be unwilling to notice it except at the wish of all parties concerned.

#### ANTISEPTICS AND DISINFECTANTS.

SIR,—I feel much obliged to Dr. Sansom for his reply in your JOURNAL of March 18th to the letter of Mr. Charles Roberts, which appeared in your paper of February 25th; and should not have troubled you with any remarks of my own, had Mr. Roberts put his strictures on my experiments with carbolic acid and other disinfectants in a less offensive and more scientific form. If, also, before rushing into print with his theories, he had taken the trouble of reading the whole of my paper, he would have observed that I had made a series of experiments in which I dipped pieces of meat in dilute solutions of the various substances used as antiseptics, and would have noticed the results obtained. Lastly, had he repeated my experiments, he would have found that the solution of carbolic acid used was sufficiently dilute not to coagulate albumen, and so could not act by "simple mechanical obstruction." This would have saved him the trouble of forming a theory, and might also have led him to doubt whether "we have already laboured too long under the incubus of carbolic acid," as well as that "it had gained its popularity on purely theoretical grounds." Allow me, again, to remark that this coagulation theory cannot account for the preservation of substances containing no albumen, such as wheat starch, farina, and various other vegetable bodies.

With respect to the action of various antiseptics on meat suspended over solutions of them, I might, like Mr. Roberts, have theorised on the subject, but preferred making the experiment, as the various substances mentioned in my paper are used under practically the same conditions. This series was made with a view of showing that these antiseptics were not disinfectants, and that actual contact of the contagious particles with the disinfectant was essential before any action could take place; but this cannot be with such substances as chloride of zinc and that class of bodies which are not volatile, while in the case of carbolic acid it can be easily understood that, being volatile, it is diffused in the atmosphere and comes into contact with the germs or means of contagion, and destroys them.

In speaking of heat as a disinfectant, it is stated that "boiling would suffice for linen and cotton goods." If Mr. Roberts really believe this, how can he in the next sentence say that "much anxiety is naturally felt by the public lest small-pox and scarlet fever should be brought home from the laundry"—and this is a fruitful source of contagion. His stoving process may be very effective; but every shopkeeper or clerk, to say nothing of every labourer, cannot go to a large firm in London to order a stove for disinfecting purposes, nor could he use it safely if he got it. The stoving of carpets, beds, etc., is not easily effected; and, unless this be done, stoving the smaller articles would be useless.

With respect to the use of sulphurous acid, Mr. Roberts believes that the cure of scabies by sulphur ointment is due to the presence of a small quantity of free sulphurous acid; whether or not on purely theoretical grounds he does not vouchsafe to inform us.

In commenting on the fact of cholera being less frequent among the workers in gunpowder factories in India and elsewhere, he says it is due probably to the presence of sulphur and sulphurous acid; and then he says that, if so small a quantity of the gas suffices to destroy rank vegetable growth, a much larger quantity in the air, though not more than can be comfortably breathed, may be fairly expected to destroy minute organic poisons and germs. Are these, or are they not, purely theoretical grounds? Is Mr. Roberts aware of the destructive action of sulphurous acid on metals, or of its bleaching action on many vegetable colouring matters, or of its use in dyeing fabrics and staining papers? Has he a theory which will overcome these slight objections to its use? I do not for a moment deny that sulphurous acid is a powerful disinfectant in cases where it can be fairly employed; but with its commonly known action on the respiratory organs, it is absurd to speak of its use in sick chambers; and had it been easily applicable, it would not have remained for Mr. Roberts to advocate now the use of a substance the value of which as a disinfectant has been known from time immemorial.

I may further remark that Mr. Roberts would have rendered a great service to the medical profession, if he had shown by experiment that sulphurous acid would prevent the spread of pyæmia in wards in which there were patients suffering from that disease. As Professor Saxtorph of Copenhagen, Professor Lister, and Mr. J. Paget have shown practically to be the case with carbolic acid.

In conclusion, I may state that, carbolic acid being now public property, I should not have considered the better worth my attention had Mr. Roberts attempted to discuss the matter as a scientific question; but, as he has made a personal attack on myself, I felt that it might perhaps lead some to suppose that my experiments were not fairly conducted, but were published from motives unworthy the consideration of a scientific man.

I am, etc., CHAS. CALVERT, F.R.S.

**DENTAL HONORARY.**—There will be an examination for the Dental Diploma of the Royal College of Surgeons early in the ensuing week. Write at once to the Secretary.

**QUESTIONS FOR EXAMINATION.**—The following questions were submitted to the candidates last week at the post examination for the diploma of member. Surgeons.—1. Mention the articular surfaces of the Superior Maxillary Bone; describe the operation for its removal and the parts cut through in the operation. 2. Describe the operation of Excision of the Globe of the Eye; and state the various operations which render the operation advisable. 3. Name the parts cut through in the following operations, viz. Harlequin, Unilateral Hernia, Amputation of the Femur at the Upper Metaphyseal Joint; and in Ligature of the Ulnar Artery at the middle of the Forearm. 4. Enumerate the various kinds of Ulcer which occur in the Female. State the cause and characteristic appearance of each, and write in full prescription for their appropriate treatment. 5. Give the Surgical Anatomy of the Intra-ventricular Region, and describe the dissection necessary to display it. 6. Mention the diseases, or other conditions which may render Laryngotomy or Tracheotomy necessary. Describe the mode of performing these operations, and state your reasons for preferring one to the other. 7. Medicine.—1. Mention the duration of the incubation and subsequent stages in Small-Pox, Measles, and Scarlet Fever, and describe the eruptions in those diseases, and state how you would severally distinguish them from each other. 2. When would you consider a patient who had had Small-Pox or Scarlet Fever, free from the risk of conveying the disease to others? 3. Mention some of the preparations of Iron and Lead in the Pharmacopæia, giving the doses and purposes for which they are employed. Write a prescription for a case of Hemoptysis.

Dr. H. R. SWANZY may address his letter to the care of Dr. Rose Cormack, 7, Rue d'Aguesseau, Paris.

#### JOHN HUNTER'S HOME.

SIR,—While thanking you for your kind advocacy of the intended memorial of John Hunter in Kensington, I hasten to remove an erroneous inference that might arise from the allusion to the property. The present occupier of John Hunter's home at Earl's Court, Kensington, informs me that the lease has several years longer to run than was generally supposed. I am, etc., JOHN J. MERRIMAN.

#### CERTAIN POINTS RELATIVE TO GENERATION.

SIR,—It is well known that by cultivation the floral envelopes of plants may be changed in form and function—single flowers becoming double or infertile monsters. Similarly the floral envelopes of the human female become changed, and infertility is usually found to prevail. The labia majora represent the calyx in two segments, and the labia minora and clitoris the corolla in three segments. The os uteri is equivalent to the base of the pistil (this organ having been cut off). Lock wards present numerous instances of misshapen hypertrophy of the clitoris and labia minora, resembling the changes in the floral envelopes of plants. Infertility is caused not only by over-culture of the generative function, but also by luxurious habits; the individual being cultivated and developed rather than the race.

Another curious subject is the attractiveness of the floral envelopes of plants. Insects aid in the fructification of the vegetable kingdom whilst they enrich themselves with its spoils; but I have never read any explanation of the fact that women delight themselves with flowers to a much greater degree than men as a general rule. I imagine that there are sympathies aroused in women, and that love and beauty are developed and intensified by the form, colour, and scent of flowers. The power of scent over the generative function is well known in animals, and the most energetic scents (castor and musk) are procured from animals. Women are sometimes rendered hysterical by powerful scents. This subject deserves study.

There is parallelism betwixt the generative function of plants and animals in the secrecy of generation. Germination occurs in the dark, whilst animals are entombed in some secret place or in the womb during development. Wild animals generate in secrecy; and man does the same, showing shame at generation. Secrecy obtains in both the vegetable and animal kingdom, and shame as well as secrecy in the higher animals, including man. To this rule there are exceptions. Domesticity alters this characteristic in some degree; and many individual men and some tribes exhibit shamelessness. All the mental traits of the animal world are developed in man more or less perfectly, rendering one man different from another, and one race the contrast of another race. This is true in matters of generation as well as on other points; and we find one man happy with one mate, like the dove; whilst another man, like the peacock, requires many wives. Again, one man makes a good parental nurse, like the stickleback; whilst another, like the hart, would injure his offspring if they were not removed from his company (as occurs with the hind and her young).

I beg to apologise to your readers for these desultory remarks. In conclusion, I would say that to man is given moral nature as certainly as physical nature, and that it is incumbent on him to control and regulate his desires and appetites agreeably to the commandments of God. In strict obedience, there is great reward in this present world, for morality and public health are inter-dependent.

I am, etc.,

FREDERICK JAMES BROWN, M.D. Lond.

Rochester, July 1st, 1871.

We are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The New York Medical Gazette, July 22nd; The New York Medical Record, July 13th; The Boston Medical and Surgical Journal, July 13th; The Madras Mail, May 15th; The Shield, July 22nd; The Philadelphia Medical Times, July 5th; The Philadelphia Medical Independent, July 8th; The Cambrian, July 21st; The Dursing Gazette, July 21st; The Western Daily Mercury, July 20th; The Durham Chronicle, July 21st; The Mansfield and North Notts Advertiser, July 22nd; The Plymouth Watchman, July 22nd; The Dublin Evening Post, July 25th; The Irish Times, July 25th; etc.

COMMUNICATIONS, LETTERS, ETC., have been received from:—

Sir Henry Thompson, London; Mr. Joseph Lister, Edinburgh; Dr. J. Crichton Browne, Wakefield; Dr. Mapother, Dublin; Dr. Protheroe Smith, London; The Secretary of the Royal College of Physicians of London; Dr. M. W. Taylor, Penrith; Mr. A. B. ## LECTURE

ON THE

## DIFFUSION, PATHOLOGY, AND TREATMENT OF ASIATIC CHOLERA.

BY

SIR THOMAS WATSON, BART., M.D., F.R.S.

[At the present juncture, when we are again threatened with an invasion of Asiatic cholera, it has appeared to us that the publication of that portion of Sir Thomas Watson's revised Lectures on Medicine, which relates to the mode of diffusion, pathology, and treatment of this disease, would be of considerable professional interest and advantage. We have accordingly requested and received authority to publish the following portions of this lecture from advance sheets of the new edition now passing through the press.]

A fourth great visitation of cholera—that of 1865-66—has come and gone since I last addressed you on this subject, and it has been far more fertile of instruction on many interesting points relative to the disease than any of the three preceding epidemics.

Very few, I imagine, of the original doubters remain unconverted to the doctrine which I have held from the beginning, that epidemic cholera is *catching*: that it results from a material poison which is portable, capable of being conveyed from place to place, and communicated from person to person—or from inanimate substances to which it clings, such as articles of furniture, or clothing. That the morbid matter floats also in the air, and may be wafted about by its currents, is a general and well-founded belief. I think, with Dr. Baly, that when it travels over great distances, as from one country or region to another, it uses the vehicle of human intercourse; but that it may be and often is diffused over smaller spaces, as from one part of a town to another, or from a tainted port to a ship anchored to leeward, by the movements of the atmosphere. The long migrations of the disease are not made rapidly. Its rate of progress never exceeds, and is often slower than, that of modern travelling. Its primary appearance in an island or a kingdom is always at its outer boundary. In our own country, for example, it first planted its foot in a seaport town on the east coast, over against the mainland where cholera was raging, and whence ships had very recently arrived. The same is true of its subsequent visitations. On the other hand, the crews of vessels sailing from healthy places remain free from the disease until they have entered an infected port, or held intercourse with an infected shore.

In his statistical report of the Royal Navy, published in 1858, Dr. Bryson says:—"The medical records of the (naval) service have been searched in vain to discover an instance in which either cholera morbus or yellow fever made its appearance amongst a ship's company, unless one or more of the men or officers had previously—within at most twenty-one days—been exposed in some house, ship, or locality where the infectious virus which emanates from persons ill of the one or the other of these diseases existed. The spontaneous origin of either malady, far away from an infected locality, is unknown in the naval service."

That the atmosphere forms one vehicle of infection seems clearly proved by some incidents ascertained respecting the last epidemic before it struck this country. I copy them from the *Times* newspaper for October 15th or 16th, 1865:—"Five miles from Gibraltar stands the little town of San Roque; and San Roque and Gibraltar were abruptly smitten by the plague, not only on the same day, but almost at the same moment. At Gibraltar it was a sudden access of the malady; at San Roque a first outbreak. At a small town near Toulon the plague fell upon the place in the night; and thirty cases occurred simultaneously between evening and morning." (This, let me observe in passing, might possibly, though not probably, have happened from the use of drinking water as a vehicle of the poison.) "At Constantinople it was observed that, while the cholera was raging, all the sea-gulls which used to flit over the waters of the Bosphorus deserted the place, nor did they reappear till the disease had departed and the atmosphere became pure once more."

Compare this with an extract from the *Dublin Morning Register* respecting the first epidemic—that of 1832:—

"A Westport correspondent, upon whose veracity we place reliance, has communicated to us the following extraordinary fact:—In the demesne of the Marquis of Sligo, near Westport House, there is one of the largest rookeries in the west of Ireland. On the first or second

day of the appearance of cholera in this place, I was astonished to observe that all the rooks had disappeared; and for three weeks, during which the disease raged violently, these noisy tenants of the trees completely deserted their lofty habitations. In the meantime the revenue police found immense numbers of them lying dead upon the shore near Erris, about ten miles distant. Upon the decline of the malady within the last few days, several of the old birds have again appeared in the neighbourhood of the rookery; but some of them seemed unable, from exhaustion, to reach their nests. The number of birds now in the rookery is not a sixth of what it was three months ago."

A striking proof that the air may be a vehicle of infection—that the poison may enter the lungs with the breath—is furnished by the fact that two pilots took the disease in consequence of having their open boat towed by a ten-fathom rope at a considerable distance astern of the steamship *England*, on board of which cholera was raging. They were never on board the vessel. Both of them had cholera, and one of them died of it. Both took the disease home, and transmitted it to their families, near Halifax, where the disease had been unknown for many years.

But although the infection thus proceeding from the bodies or the excretions of the sick, and entering by the lungs the bodies of the healthy, may strike and destroy individuals here and there, it seems very doubtful whether the disorder can become epidemic, except in certain conditions of the atmosphere.

It appears from the extremely interesting report of Mr. Glashier on this subject, that "the first three epidemics were attended with a particular state of atmosphere, characterised by a prevalent mist" (he is speaking of London and its immediate neighbourhood)—"thin in high places, dense in low. During the height of the epidemic in all cases, the reading of the barometer was remarkably high, and the atmosphere thick. In 1849 and 1854, the temperature was above its average, and a total absence of rain, and a stillness of air amounting almost to calm, accompanied the progress of the disease on each occasion. In places near the river the night temperatures were high, with small diurnal range." He goes on to enumerate, as characteristic of the atmosphere at these periods, "a dense torpid mist; and air charged with the many impurities arising from the exhalations of the river and adjoining marshes; a deficiency of electricity; and (as shown in 1854) a total absence of ozone, most probably destroyed by the decomposition of the organic matter with which the air in these situations is strongly charged."

The ozone here mentioned is endowed, as I told you formerly, with peculiar purifying properties. It has a high oxidising power, in virtue of which it unites with, decomposes, and so destroys miasmata, while it is at the same time itself proportionately destroyed. There is no ground for ascribing cholera, as some have done, to the absence of ozone—except in the sense of there not having been a sufficient quantity of it in the atmosphere to counteract all the poisonous miasm which actually produces that disease. The total absence of ozone affords presumptive evidence of the presence of atmospheric impurities.

A remarkable law of *altitude*, that is of elevation above the level of the Thames, has been announced by Dr. Farr as governing the mortality from cholera in this metropolis; and if here, so doubtless, under similar circumstances, elsewhere. "The elevation," he says, "of the soil in London has a more constant relation with the mortality from cholera, than any other known element." The mortality is inversely as the altitude.

This law of altitude—so important and so practically valuable—is but an expression of the result of many concurrent circumstances. The material poison of cholera will be likely to gravitate, as the marsh poison gravitates, with which it has many points of analogy, to the lowest part of the atmosphere; where the high barometrical pressure is the greatest, and vaporous diffusion therefore the least; where unwholesome exhalations from the soil and from the water are the most abundant; where the dispersing and diluting influence of winds is least felt. Indeed the air may be completely stagnant while on the neighbouring heights a brisk breeze is blowing. The lower regions of the atmosphere are the hotter also as well as the moister; and under the agency of a high temperature the organic impurity with which the air is charged runs more readily into decomposition. The inverse law of altitude is therefore an intelligible law. We see also how it may sometimes be disturbed or broken, under exceptional circumstances.

At the time when Mr. Glaisher's observations were made, the river Thames had become, without metaphor, the common sewer of this enormous and ever-growing town. Foul with the daily and hourly influx of abominable filth, it was offensive to the senses, and a cause of added foulness to the incumbent atmosphere. When we learn from Mr. Glaisher that during the summer months the night temperature of the river is considerably above the minimum temperature of the air, and that its vast area was simmering all night long, and throwing off clouds

of noisome and noxious vapour, we need be at no loss to account for the special unhealthiness of those quarters of the town which lie nearest to its banks.

But however unwholesome and pernicious the atmosphere may thus become, it cannot generate cholera, unless the specific exciting poison of that disorder be present also. In the autumn of 1859 the Thames stank horribly; yet we had no cholera. On the other hand, there is good reason, I say, to believe that this poison can never create a spreading pestilence, unless it meets with a congenial atmosphere. The foul air lends force and diffusion to the poison, and aids, or causes, its increase.

Notwithstanding that the choleraic poison in an invisible and impalpable state may thus pervade, and be communicated through, the air, it had long been conjectured, and it is now perfectly certain, that (horrible thought), we may eat and drink the poison, and so obtain the disorder. That, as I shall have to tell you, is the case also with enteric fever; the discharges from the alimentary canal are at once the main outlet for the poison and the chief source of infection. The late Dr. Snow was the first to broach the notion that the poison may be *swallowed* with the food which we eat, or the water which we drink; and that its multiplication takes place within the system, whence, by the alimentary canal, a new and abundant stock of it is voided. He showed how easily portions of the rice-water excretions, colourless and but slightly odorous as they are, may, without our notice, come to adhere to our food during its preparation, or its consumption. And the horribly disgusting fact had been made too certain by the unchallengeable disclosures of the microscope, that the water which is supplied by the several water companies for domestic purposes to this great city habitually contained visible particles of human ordure. Some striking facts had been collected by Dr. Snow, which warranted the presumption that a most fearful outbreak of cholera in Soho was attributable to the water of a certain pump, contaminated from a neighbouring sewer. A remarkable converse fact had been reported by the late Sir William Lawrence. Bethlem Hospital, and an asylum for children called the House of Occupation, stand near together on an open space of ground between fourteen and sixteen acres in extent, lying in the parish of St. George, Southwark. Being dissatisfied with the filthy water then supplied by the Lambeth Company, the Governors some forty years ago sank Artesian wells on the premises, and the pure water thus procured is used exclusively in the two institutions, which between them number about seven hundred residents. There was not a single case of cholera in the Hospital or in the House of Occupation in any of the first three epidemics; although the disease prevailed extensively in the parish, and in the streets in their immediate vicinity.

The result of an inquiry suggested by the Board of Health into the effects of the consumption of impure water during the second and third cholera epidemics was favourable to Dr. Snow's theory. Mr. Simon reported that "the population drinking dirty water appeared to have suffered three and a half times as much mortality as the population drinking other water."

That cholera may indeed be contracted by drinking a mixture of choleraic discharges and water, is demonstrated with all the force, if not with the reality, of an experiment, by the facts thus stated by Mr. Macnamara, a gentleman practising in India:—"I may mention the circumstances of a case in which the most positive evidence exists as to the fact of fresh cholera dejecta having found their way into a vessel of drinking water, the mixture being exposed to the heat of the sun during the day. Early the following morning a small quantity of this water was swallowed by nineteen persons. (When partaken of, the liquid attracted no attention either by its appearance, taste, or smell.) They all remained perfectly well during the day, ate, drank, went to bed, and slept as usual. One of them, waking next morning, was seized with cholera; the remainder of the party passed through the second day perfectly well, but two more of them were attacked with cholera the next morning; all the others continued in good health till sunrise of the third day, when two more cases of cholera occurred. This was the last of the disease; the other fourteen men escaped absolutely free from diarrhoea, cholera, or the slightest malaise."

At the time of this remarkable occurrence there was no cholera in the neighbourhood, nor had there been for several years, nor, so far as Mr. Macnamara is aware, has there been since.

Mark here the period of incubation, varying from twenty-four hours to two or three days; mark also that the majority of those who drank the tainted water escaped unhurt; in other words, that some persons take the contagion more readily than others.

The epidemic of 1865-66 has illustrated in a very remarkable way the soundness of Dr. Snow's theory. The prevalence of the epidemic in this country was clearly a step forwards in the progress of the malady in its rapid advance from Mexico to Egypt, and thence to various places on the eastern and southern coasts of Europe, and in the basin of the

Mediterranean. Mr. Simon lays it down as an axiom to be generally accepted in State Medicine, that "contagions current on the continent of Europe must be deemed virtually current in England." The disorder first showed itself here in the autumn of 1865, as usual at a seaport—Southampton. Then, as usual, it slept apparently for a while, to reappear and diffuse itself, after fresh importations from the Continent, and at its customary rate of increase, in the spring and summer of 1866; when, in the middle of July, there occurred in the eastern part of London an increase of the disorder so sudden, vast, and rapid as to warrant its being spoken of as an explosion. This outburst was limited to a certain definite and remarkable area, the line of limitation having an obvious relation, not to *soils*, but to *houses*; it was contemporaneous over that area, and stopped short abruptly within and along the line of limitation. It had a week's duration only. Its cause began to act during the week ending on July 14, and ceased to act in the week following. On the sixth day of its increased activity cholera had appeared in every portion of the before-mentioned area; the rate of its increase, as compared with the previous week, was nearly seven times greater than in the rest of the metropolis; while in the subsequent week the rate of increase became virtually the same over the whole of London. It is worthy of remark that there had been no undue prevalence of diarrhoea in the affected area.

This strange and definite outbreak must have had some adequate and definite cause; and, upon careful search, there was found evidence only just short of demonstrative proof—evidence which I cannot stop to state in detail, but which you may study in the ninth Report of the Medical Officer of the Privy Council—that this local calamity was produced by the temporary distribution to the area in question of unfiltered and infected water from certain reservoirs of the East London Water Company.

The peculiar blue mist which was noticed in the epidemic of 1854 was present also in the last epidemic. Mr. Glaisher says of it:—"On some days no trace of the mist has been visible; on other days it has been seen for parts of the day only. It has extended from Aberdeen to the Isle of Wight. This mist increased in intensity when viewed through a telescope; usually no mist can be seen when thus viewed." As in previous epidemics, there was a marked deficiency of ozone in the atmosphere. In other respects the meteorological phenomena were in remarkable contrast with those which had occurred during previous visitations of the cholera, and the law of altitude was broken by the predominance of more powerful influences.

With respect to the mode of propagation of the disease, Mr. Simon uses this strong language:—"It cannot be too distinctly understood that the person who contracts cholera in this country is *ipso facto* demonstrated with almost absolute certainty to have been exposed to excremental pollution. Excrement-sodden earth, excrement-reeking air, excrement-tainted water—these are for us the causes of cholera."

He adds: "The local conditions of safety are, above all, these two: (1) that, by appropriate structural works, all the excremental produce of the population shall be so promptly and so thoroughly removed, that the inhabited place, in its air and soil, shall be absolutely without fecal impurities; and (2) that the water supply of the population shall be derived from such sources, and conveyed in such channels, that its contamination by excrement is impossible." And he concludes with the pious hope that "for a population to be poisoned by its own excrement will some day be deemed ignominious and intolerable."

Our knowledge of the *morbid anatomy* of cholera has become more complete and more exact during the last epidemic.

Drawing my conclusions not from any experience of my own, but from numerous and very careful *post-mortem* inspections made by Dr. Parkes, by Dr. Johnson, by Dr. Sutton, and by others, I believe it may be stated as a rule—a rule broken sometimes, no doubt, by disturbing but intelligible circumstances—that in cases of death *during collapse*, when the examination is made sufficiently early, the lungs are found to be shrunken, light, dry, and pale—in one word, unnaturally bloodless; the left ventricle of the heart is contracted and nearly empty; its right cavities, the trunk of the pulmonary artery, and the systemic veins, much distended with blood; the mucous membrane of the intestines free from congestion, and pale.

In some of these cases the lungs, though very light in weight, are of a dark colour, which gives them an appearance of congestion. This colour Dr. Johnson refers to a backward engorgement of the *bronchial* veins and capillaries, consequent upon the block in the pulmonary artery and its branches.

When death has occurred during incipient and imperfect reaction, the morbid conditions disclosed by dissection are the reverse of these. The lungs are congested, sometimes even inflamed; and the mucous membrane of the intestines is also loaded with blood.

These are points which bear closely upon the pathology of the dis-

ease; and upon its true pathology rests its rational treatment. To these I now turn.

There are two conflicting theories as to the pathology of cholera; and there are two conflicting principles—which accord with and flow from these theories respectively—as to its proper treatment. Upon this momentous problem of treatment, the final appeal must clearly be made to experience.

It is acknowledged on all hands that the primary and special danger in cholera lies in its period of collapse. Now it was a very natural and plausible theory which attributed this state of collapse to a drain upon the blood by the profuse and repeated fluxes from the stomach and bowels, whereby the blood, being robbed of its more liquid ingredients, and made thick like tar or treacle, became incapable of flowing freely, if at all, through its natural channels; and thus the circulation coming ultimately to a stop, life stopped also. And the practice suggested, and put in force, as a direct corollary to this theory, was that of endeavouring to arrest the destructive flux by astringent drugs and by opium, to sustain or urge on the lingering circulation, and to restore the spent strength and the lost animal warmth by alcoholic and other stimulants. Upon similar grounds was advocated the dilution of the thickened blood by water injected into the veins.

It is affirmed, on the other hand, that the condition called collapse is not due to the excessive discharges from the body; that those discharges are really eliminative of the poison, or of the products of the poison, which caused the disease, and are to be permitted, or even encouraged, rather than checked; that to pen the poison and its products within the body is to fight against the conservative forces, and to do what art can do to ensure the mortal agency of the poison, and, therefore, that astringents and opiates can do no good, but are, on the contrary, positively hurtful.

Were the first-mentioned theory true, there must be a discernible relation between the alleged cause and its effect. The greater the amount of the intestinal discharges, the more certain and the more decided should be the resulting collapse. But no such proportion has, in fact, been observed. Nay, the very reverse not seldom obtains. The most hopeless cases are those of collapse after very scanty discharges, or with no discharges at all.

Again, if the collapse were indeed owing to the drain upon the blood effected through the intestinal discharges, it would be prolonged, deepened, and rendered more perilous, by the continuance of those discharges; whereas it is notorious that patients emerge from the state of collapse, and recover, while the evacuations nevertheless go on, and that the cessation of the evacuations during collapse is a fatal sign. "It may confidently be asserted", says Dr. Parkes, "that there is no one who has seen much of cholera who does not know that, exclusive of the mildest forms of the disease, a case with little vomiting or purging is more malignant and more rapidly fatal than one in which these are prominent symptoms."

Tested, then, by the evidence of acknowledged facts, this theory must be pronounced a failure, and the treatment founded upon it a mistake.

In truth, a fallacious analogy has been assumed between the collapse or exhaustion arising from a drain upon the blood and the collapse in cholera. In one single point—namely, the smallness and weakness of the arterial pulse (in other words, the defective circulation of the blood)—the two may seem to touch each other. In almost every other point they differ widely. A person exhausted by loss of blood, or by a long continued drain upon that fluid, is in a state that is very near to syncope. When the exhaustion is extreme, if he assume the erect posture, he faints outright, and becomes unconscious. To walk, to stand, or even to sit up, is simply impossible; whereas, in the collapse of cholera, a patient, with death stamped apparently upon his features, with no pulse to be felt at his wrist, with a blue and icy-cold skin, may be able to walk about the room, and to perform many of his usual functions. He does this indeed at the peril of his life; but the fact that he is capable of such an effort proves that there is an essential difference between cholera collapse and ordinary syncope. The exhausted man, if he recover, recovers slowly; the repair of his impoverished blood is necessarily a gradual process. The cholera patient rallies from his collapse at once, if at all. He may be in full collapse to-day, and convalescent the day after to-morrow, and apparently but little the worse for the terrible disorder through which he has so recently passed. "I have seen", says Mr. Grainger, "a man stand at his door on Wednesday, who on Monday was in perfect collapse." Again, the way in which remedies tell upon the two contrasted conditions is totally and instructively unlike. The coldness and faintness of exhaustion are relieved at once by a glass of wine or of brandy; the pulse instantly acknowledges the virtue of the stimulus. But alcoholic stimulants do not warm or invigorate, even for a moment, the patient in choleraic col-

lapse; rather, they seem to make matters worse. On the other hand, blood-letting has often brought marvellous relief under collapse; while to draw blood from a person who is fainting from exhaustion would probably ensure his death, and would certainly aggravate his danger. Take the following instance, recorded by Sir Ranald Martin, of the effect of venesection. "On visiting my hospital in the morning, the European farrier-major was reported to be dying of cholera. I found that during the night he had been drained of all the fluid portion of his blood. His appearance was surprisingly altered: his respiration was oppressed; the countenance sunk and livid; the circulation flagging in the extremities. I opened a vein in each arm; but it was long before I could obtain anything but trickling of dark treacly matter. At length the blood flowed, and by degrees the darkness was exchanged for more of the hue of nature. The farrier was not of robust health, but I bled him largely; when he, whom not a moment before I thought a dying man, stood up and exclaimed, 'Sir, you have made a new man of me'. He is still alive and well."

The question has naturally been put, "Is it possible to reconcile facts of this kind with the theory that the collapse of cholera results from the loss of the liquid constituents of the blood?" If Sir R. Martin's hypothetical statement that his patient "had been drained of all the fluid portion of his blood" were an accurate expression of facts, can we conceive it possible that he could have "made a new man" of him by extracting largely the blood which remained in the vessels?

The main advocate in this country, and, as I think, the triumphant advocate, of what may be called the evacuant or cleansing practice in cholera, is your present able professor of physic, Dr. George Johnson. To him is justly due the great merit of having established, by his persevering efforts in the face of much opposition and discouragement, the worth and efficacy of that practice, although he was not the first to recommend or to adopt it. It was, in fact, tried, with favourable results, nearly half a century ago, by English practitioners in India; its professed object being that of getting rid of offensive morbid secretions. The practice thus vouched for by Dr. Johnson is directly in accordance with, and serves to confirm, that view of the pathology of cholera which, by a methodical display of numerous facts, and by a process of close and conclusive reasoning, he may fairly challenge as his own. Briefly, he holds, as many before him held, that the phenomena of cholera result from the entrance of a peculiar poison into the blood, where it probably undergoes, like that of small-pox, a rapid process of self-multiplication, and spoils certain of the blood-constituents, which are then ejected through the mucous membrane of the alimentary canal; that the feelings of general oppression and *malaise* sometimes experienced before the onset of the bowel symptoms, are indicative of blood-poisoning; that the copious discharges are expressive of the efforts of nature to throw off a noxious material, and really form, therefore, a necessary part of the process of recovery; and that, if the pouring forth of the vascular excretion be checked (as it can, perhaps, be by opium), the risk of fatal collapse is thereby increased. He declares that the results of his own practice, founded on these views, have amply justified them; and a considerable body of other evidence has now been furnished in support of the same plan of treatment.

It is plain that, if "elimination" be a condition of recovery, the method of elimination is Nature's method, which Art may help or hinder—help by the cleansing method, hinder by the astringent.

In discussing the principle of treatment I have shot ahead of several points in the novel, interesting, and, to my mind, satisfactory exposition of the general pathology of cholera by Dr. Johnson.

Remember the abrupt contrast seen, upon early examination of the body after death during collapse, between the anemic condition of the lungs, and the gorged condition of the trunk of the pulmonary artery and of the systemic veins. What is the explanation of this sudden arrest of the stream of blood in the small arteries, just before it reached the capillaries? Were the arrest of motion due to gradual thickening in consequence of the continued abstraction of its liquid portion, it would be found stagnating in the capillaries, as well as in the arteries. Bear in mind that one characteristic symptom of cholera—that symptom which, irrespectively of the fatality of the disease, renders it truly a disease to be dreaded—consists in very painful cramps of the larger muscles of the body. These contractions, it may be assumed, are produced by the choleraic poison, just as we know they are producible by the poison of strychnine. Dr. Johnson supposes that a similar spasm or cramped state of the muscular fibres which embrace the minute pulmonary arteries, is caused by the same choleraic poison, and bars these slender channels against the advancing blood: that the stopcock action which I have so often explained to you, comes here into play. The thickening of the blood is a consequence, and not a cause, of the arrested circulation and the collapse. Precisely the same blood-thickening occurs as a result of the impeded circulation through the lungs which is associated with long

continued, extreme, and fatal apnoea, as I have explained to you in a former lecture.

The true explanation of the fact that mere diarrhoea, however profuse, does not thicken the blood, is probably, as Dr. Johnson suggests, that water is rapidly absorbed from the soft tissues to take the place of that which escapes from the alimentary canal. Acting on this principle of physiological hydraulics, we remove a dropsical accumulation by the action of a hydragogue purgative.

Surely the theory that I have now placed before you seems a reasonable theory. It is founded on a true analogy; it is consistent with the symptoms noticed during life, and with the conditions discovered after death. We may, therefore, legitimately regard it, until fairly refuted, as a sound as well as a most ingenious and important theory. In truth, it derives strong confirmation from the fact that it unlocks, like the right key, the whole of the pathological intricacies of the disease. Thus the emptiness of the systemic arteries accounts for the extinction of the pulse at the wrist, for the cadaverous sinking in of the eyeballs and falling of the features, for the blueness and coldness of the skin, and for the absence of syncope. The circulation stops, not from debility of the heart, as in exhaustion, but in consequence of a direct mechanical impediment to the onward course of the blood. We can understand the impotence of brandy against this condition; and how, on the other hand, bleeding may help, both by relaxing the spasm and by unloading the distended right heart, to restore the circulation. Into this explanation Dr. Johnson presses, plausibly enough, the singular effect of the injection of fluids into the veins of these patients. It appears that, to be most influential, the fluids must be hot; and he concludes that they act partly by diluting the morbid blood, but chiefly by relaxing, through their warmth, the spasm of the smaller arteries. The blood then flows on again, and the symptoms of collapse are for a time removed. Again, the husky whispering voice is owing, not to muscular weakness, but to the small volume of tidal air in the respiratory currents. As but little venous blood reaches the lung-tissue proper, there is but little demand for air to meet and decarbonise it. The respiration accordingly becomes shallow, and the vocal pipe, feebly blown through, refuses to speak. Under the temporary impulse of the warm injections, the voice regains its usual tone and note. Once more, there are chemical and less obvious changes which receive their explanation from this theory, and further attest its truth. The stream of blood through the pulmonary capillaries being greatly lessened, the supply of oxygen is proportionally reduced in quantity. Hence during the stage of collapse there is defective oxygenation of the blood and of the various tissues of the body, coldness and blueness of the surface, diminished exhalation of carbonic acid, and suppression, nearly absolute, of bile and of urine—carbonic acid, and the chief constituents of bile and of urine, being all results of oxidation. That this is the correct explanation of the suppression of bile and urine during collapse is rendered all the more probable by the curious fact that, when a nursing mother becomes the subject of cholera, and falls into collapse, the secretion of milk continues unchecked. Now the chief constituents of milk—casein, sugar, oil, and water—may be obtained from the blood without the addition of oxygen. They are *not* products of oxidation.

If the doctrines advanced by Dr. Johnson be well-founded, as I firmly believe them to be, it must be wrong to dam the choleraic poison and its products within the body. Even when those products have, in one sense, been separated from the system, they may produce highly noxious effects if they remain shut up in the stomach or bowels, there to ferment and decompose. Admitting, as we must, that a minute quantity of the morbid excretions swallowed with water may suffice to produce the disease, a large quantity retained, through weakness of the expulsive powers or otherwise, can scarcely be harmless. Rather may we expect that its expulsion will tend to liberate the patient from danger and discomfort; just as the opening of large abscesses, and the discharge of foul pus and imprisoned gases, are often seen to rescue, as if by magic, a sick man from apparently impending dissolution. Whatever may have been Dr. Johnson's earlier purpose, he does not now propose to *evacuate* discharges from the mucous surface of the digestive canal; but simply to facilitate the removal of matters lodged there. And this he would do by emetics, by draughts of tepid water or other diluents, or by castor-oil, of which the action is both speedy and gentle. The recommendation of the evacuant plan must, after all, lie in its comparative *innocence*, and its worth has already been put closely and extensively to the proof.

In the fiftieth volume of the *Medico-Chirurgical Transactions* there is a most instructive communication from Drs. McCloy and Robertson. They show that, of 375 cases of cholera admitted into the Liverpool Parish Infirmary in the last epidemic, 161 proved fatal—a gross mortality, under all the modes of treatment adopted, of 42.93 per cent. Of these cases, 91 were treated with astringents and stimulants, camphor

and iced water, applications of ice, and hypodermic (opiate) injections; and the mortality per cent. of these cases was 71.42. 87 cases were treated with castor-oil, and with a liberal use of food and alcohol; and the mortality was 41.37 per cent. 197 cases were treated with castor-oil only, and the mortality was 30.45 per cent. The authors of the paper declare that "recovery never occurred without the continuance of the intestinal discharges; or their restoration, if previously arrested."

The late Inspector of Prisons, Mr. Perry, had charge, in 1832, of the cholera patients in the Marylebone Workhouse. He told me that, though he had no specific notes to refer to, he distinctly remembered that about thirty patients were treated with castor-oil; and that they did better than any of the others.

When I last spoke on this subject in these Lectures, I stated that the few recoveries which I had witnessed had all taken place under large and repeated doses of calomel, but that I could not venture to affirm that the calomel cured them. At present, I am much disposed to believe that, by its cleansing action, the calomel may have helped the recovery; and, after all that I have since seen, heard, read, and thought upon the matter, I must confess that, in the event of my having again to deal with the disorder, I should feel bound to adopt, in its generality, the evacuant theory and practice; and to avoid alcoholic stimulants and opiates.

Now, if this theory and practice in respect of cholera be true and right, the practice ought to be right in respect of the associated diarrhoea also; and it is strongly affirmed by those who have largely tried it, that it is right, inasmuch as it is eminently successful. Dr. Johnson avers that he has found it so.

Hear the concurring testimony of Drs. McCloy and Robertson. "Our experience of diarrhoea was very extensive. Several thousand cases came under our observation in the different dispensaries connected with the West Derby Union and in the Liverpool Parish Infirmary. Among these were doubtless many which would have recovered under any mode of treatment, or by the *vis medicatrix nature* alone. But there were many, too, of a most severe choleraic type. The treatment adopted was generally evacuant in its nature; and consisted in the administration of castor-oil, calomel, rhubarb, or magnesia. In every case relief was afforded 'pleasantly, quickly, and safely.' It was but seldom that more than two or three doses of oil were required." The medical officers of the Bootle Dispensary depose to the same effect: "We certainly had less trouble with the evacuant mode of treatment. Our patients seldom gave us a third visit; two doses of castor-oil or rhubarb mixture were generally sufficient to cure the disease." "We never saw a diarrhoea patient, treated with evacuants from the commencement of his attack, require subsequent removal to hospital. In a large proportion of our cases there was 'premonitory diarrhoea' which had been treated, often for four or five days, with astringents. Diarrhoea patients undoubtedly recover when treated with astringents; but the recovery is not consequent upon the arrest of the discharges, as these are invariably restored before the patient feels well."

In the face of this and of much similar evidence, I feel bound to say that the rules laid down by Dr. Johnson for the treatment and prevention of diarrhoea and cholera, seem now to me safer and better than the less discriminating advice which heretofore I gave you, "whenever a suspicion arose that cholera was present in the community, not to try, in cases of diarrhoea, to carry off the presumed offending matter, but to quiet the irritation and to stop the flux as soon as possible, by astringents, aromatics, and opiates."

No doubt, the true indication of treatment is, to stop the flux as soon as possible; but this may sometimes be best effected (as also in "crapulous diarrhoea, and in the summer cholera of Sydenham") "by carrying off the offending matter."

**POISONOUS SILK GLOVES.**—Dr. J. T. Dickson writes in a daily paper: On Saturday last a patient called upon me and exhibited her hands covered with very irritable blebs or blisters. After minute examination and questioning for cause, she told me that during the week she had purchased in Marylebone a new pair of silk gloves for two shillings, had worn them during a journey to Manchester and back, and that her hands had borne these vesications ever since. She wore the left glove more constantly than the right, and the left hand is consequently much more affected than the right. I desired her to bring the gloves to me, and I found that they were of good quality spun silk, dyed of a light-brown colour, the dye apparently being an aniline dye of coal-tar origin. Spun silk takes the bright colours made from aniline very well, but the use of articles so dyed is dangerous. In the museum of the College of Surgeons are preserved some brightly-coloured children's socks, which gave rise to a similar affection on the feet of a child (I believe in France). I also believe that the late Marquis of Hastings was once similarly affected.

# CLINICAL LECTURES ON MENTAL AND CEREBRAL DISEASES.

By J. CRICHTON BROWNE, M.D., F.R.S.E.,

Medical Director, West Riding Asylum; Lecturer on Mental Diseases to the Leeds School of Medicine; etc.

## II.—HYSTERICAL MANIA.—(Concluded.)

WHAT, then, are the symptoms of this well marked type of mental disease called hysterical mania? Some of these have been already brought before you in connexion with the cases introduced, but it may be well to give a separate and succinct sketch of them. The preludes to the attack are generally debility, with defective appetite and menstrual disorder. The attack itself begins suddenly, either without any warning, or after a few days of depression or silent reserve. Loquacity and restlessness are its earliest and most permanent symptoms. Philosophers have asserted that women possess a superiority over men in their powers of conversation; and this remark is powerfully confirmed by the disease under consideration. The untiring vigour with which a delicate-looking girl will talk incessantly for twenty-four hours is positively amazing. She seems to gather strength as she goes on; for, as the disease advances, volubility becomes greater. The utterances thus fluently poured forth are at first disjointed, but rational sentences; inopportune, but sharp and comprehensible remarks; and then mere broken and interjectional phrases. The incoherence in this disorder, however, is never comparable with that of acute mania, even in its worst phases, as some shreds of sense may be found in it; some laws of association may be observed to regulate it. In the midst of a torrent of what sounds meaningless chattering, you will be surprised by some clever or pertinent expression—some words that prove that memory is active, and that perception is acute. Very soon after talkative excitement is established, it assumes an emotional complexion. This is happy and joyous, and there are fits of laughter and musical outbursts; or pensive and sad, and there are profuse tears and convulsive chokings. Most frequently these emotional states alternate with each other, while the mind is gradually sicklied over with the pale cast of eroticism. In a great majority of cases, the morbid excitement of what has been called the tender emotion is distinctly observable. There is increased agitation produced by the presence of a member of the opposite sex; there are rhapsodies addressed to some real or ideal lover; there are sentimental cravings; there are passionate invocations; there are lascivious movements, obscene speeches, and even filthy acts; and along with these erotic manifestations there are perverse and mischievous propensities. Dugald Stewart said that women surpass men in docility and aptitude to learn. After watching a few cases of hysterical mania, you will see reason to doubt at least the first part of that statement. The intractability, obstinacy, and noisy spitefulness displayed are truly disheartening to those who have to deal with them. In the worst cases, there are also destructiveness, violence, and degraded habits, and perverted appetites leading to consumption of cinders or garbage. Throughout the disease, however, in the worst cases as well as the mildest, a peculiar power of rallying is generally preserved. Self-control is not altogether lost. The current of excitement can be stemmed for a few seconds. A degree of intelligence can be exhibited which seems incompatible with such decided mania. As the excitement diminishes and recovery is approached, there is either depression of spirits, listless indifference, or acute sensitiveness. In some cases, there are confusion of thought, a sense of bewilderment, and an obliteration of memory as regards the whole or large portions of the attack.

Along with these mental symptoms there are, at the beginning of hysterical mania, headache (often limited to the frontal region), loss of appetite, and muscular tremor. In a few cases there is also spinal tenderness in the dorsal region, with pains in the abdomen and legs. Pallor of the countenance and dilatation of the pupils are always present. The pulse is only slightly increased in frequency; the skin is cool and moist; and the tongue clean, or only coated with a thin white fur. There is usually a profuse flow of light-coloured limpid urine. A very fair amount of sleep is obtained; but, as the attack progresses, this gradually lessens in amount, until, at its height, the whole night is perhaps passed without even a snatch of rest. As sleep is reduced in quantity, cutaneous sensibility is heightened, until a state of general or local hyperæsthesia is attained. The slightest touch causes, or seems to cause, sharp pain. This condition, however, is not constant, but comes and goes, and is occasionally replaced by anaesthesia or bluntness of feeling. There is invariably muscular restlessness throughout

the whole stage of excitement. The play of features, or rather the contortion of the face, is constant and inexhaustible. All sorts of gestures and gesticulations are practised. Spasms and twitches affect the voluntary muscles, and sometimes the involuntary ones also, producing choking, hiccup, and gripping pains. Not rarely there is a vehement trembling of the eyelids, and also palpitation of the heart. The excitement and rapid movements cause some acceleration of the pulse and elevation of temperature, but ordinarily the pulse and temperature undergo less change than might have been anticipated. A sudden and transitory rise in either may happen without any obvious explanation, but their average range is tolerably normal. As the attack proceeds, constipation of the bowels comes on, as well as menstrual irregularity, if that has not existed before the incursion of the insanity. Throughout the whole attack, the body retains its plumpness in an almost miraculous manner. Notwithstanding that little food is taken, and that wear and tear are excessive, emaciation is warded off. When convalescence is reached, weakness is much complained of, and also frequently the pain under the left breast, first described by Dr. Todd, and referred by him to reflex sensation. If I might venture in any way to amend what has been stated by so eminent an authority as Dr. Todd, I would tell you that this pain is felt more in the splenic than in the submammary region; and that it is in a few cases associated with profound anæmia, without leucorrhœa. Along with this pain, during convalescence after hysterical mania, there are occasionally gastrodynia of a severe kind, and various erratic neuralgic pains. Respecting the duration of an attack of hysterical mania, I can give you no reliable information. In some cases, it terminates in a few days; in others, it continues for months. It is rarely, however, that any one attack, even when unmodified by treatment, lasts more than three months.

To bring more practically before you, in the concrete, what I have told you about hysterical mania, or at least part of what I have told you, I shall now recall to you the case of S. M., aged 18, single, a dressmaker from Leeds, who was discharged recovered on the 14th of December last. This girl had been a pupil-teacher in a Wesleyan school, and had applied very closely to her studies and passed her examination creditably at sixteen years of age, when all at once her health failed and she became melancholy and hysterical. She was then sent to the country, and in about six weeks became quite strong again. Up till August last she was in good health and employed as a dressmaker. Then, however, she became weak and pale and ill, and was noticed to be more sensitive than was her wont. No specific ailment could be discovered, but her debility grew upon her until the beginning of September, when she became quiet and dejected. In this state she remained for two days, and then suddenly launched out into vociferous cheerfulness, which passed through various stages of aggravation, and finally necessitated her incarceration in this asylum on the 20th of September. One cousin of hers had been insane, and another epileptic. Her mother had always been nervous. Out of five brothers and sisters of hers, four had died in infancy. When admitted here she was talking in a loud tone of voice and rambling manner upon many subjects, interlarded with fragments of texts and prayers. She understood what was said to her, answered questions, only too glibly and copiously, and could remain quiet for a little when ordered peremptorily to do so. She insisted upon pacing up and down and tossing her arms about. She said she had pain on the right side of her head and "all down the spine of her back", so that she could not lean upon a chair nor allow the skin over the vertebrae to be pressed or rubbed. She was of average height, exceedingly pale with fair hair and widely dilated pupils; the skin was moist. There was slight increase of vocal resonance over the apices of both lungs, and the heart-sounds were loud and widely diffused. During the night of the 20th she slept well, but as soon as she awoke on the morning of the 21st recommenced to vociferate. She also wept and laughed, and could not be persuaded to take much food. On the 28th September she is reported as somewhat more composed, and as having taken abundant nourishment, but being so weak as to be unable to stand. On the 30th she is said to be very excitable and unmanageable; also more incoherent and destructive, having torn up some clothing and flowers in the airing-court. A specimen of her incoherence was taken down *verbatim*, and I now read it to you. "Gold, silver, waxworks, yellow, pink, and white—Get a substitute—Reverend So and So—Plenty of law-givers—Two brothers—Bible—Eternal life and death—A man I love to honour—Honour to whom honour is due—My master—Give him a life pill—Self praise is no recommendation—Venerable old age—Fox and Pitt"—All this, and endless quantities of the same stuff, with the most extraordinary volubility. On October 1st, the entry is in the case-book:—Pulse 90; tongue clean; takes her food indifferently, talking incoherently, but remains in bed. On the 2nd it is:—Has been much excited all day, crying out in a loud harsh voice; very emotional; attitudinises and throws herself into tragica.

postures; is alternately erotic and religious in her conversation, love, however, being her chief theme. Pulse 130; tongue clean; bowels have not acted for two days. On October 3rd, Has had some broken sleep; very incoherent and mischievous; raves mostly about some one named "Cavosa," to whom she refers in amorous terms; pulse 120. On October 4th, Is a little quieter; pulse 123, and irritable; pupils much contracted; face pale; tongue clean. On October 12th, Is decidedly improved; capable of rational conversation; has not menstruated for six weeks. On October 23rd, Still improving, but very weak; is quiet and downcast; employed in sewing. After this she gained ground steadily until the date of her discharge.

No difficulty attends the differential diagnosis of hysterical mania. It could only be confounded with acute mania, and the excited stage of acute dementia. From the former it is distinguished by its history, by the less deep and universal involvement of the mind which characterises it, by the character of the delirium, by the moisture of the skin and comparative cleanness of the tongue and unaltered state of the secretions, by the absence of great muscular strength or rigidity and of rapid emaciation, and by the slightness of the modification of the pulse and temperature; from the latter it may be known by the absence of the stupidity and fatuity which mark the delirium of acute dementia, and of that chilled and livid state of the hands, feet, and features, which accompanies it.

The prognosis of hysterical mania is equally simple with its diagnosis, and is invariably favourable. The tendency of the disease is to end in recovery. But this tendency may be fostered and encouraged, and the duration of the disease much curtailed by judicious treatment. The only danger to be apprehended is that of relapse; but this is sometimes considerable, as many as five and six relapses taking place in one case.

Fortunately, there is no morbid anatomy of hysterical mania. In one case only have I seen death occur in consequence of an intercurrent condition. That, however, was the most inveterate and distinctive case of hysterical mania that I ever encountered, and I shall therefore read to you the notes of the *sectio cadaveris* as far as they bear upon our present subject. The skull was of average thickness, but unsymmetrical, bulging posteriorly to the left. On removing it, the dura mater was seen to be tense, without folds or wrinkles, as if it were tightly stretched over the brain. On opening it, the brain expanded and bulged over the sawn edge of the skull as if it had been subjected to compression. The whole brain weighed forty-six ounces. There was very slight thickening of the arachnoid. The gyri were plump and in close apposition to each other. The grey matter was extremely pale, especially in its deeper layers, which were scarcely distinguishable from the medullary substance, which was of unusually firm consistence. The ventricles were of average size and contained no fluid. A small round body, of firm gelatinous consistence and about the size of a pea, lay imbedded at the anterior end of the third ventricle, fastened there by little fibrous attachments. The middle commissure was of extraordinary thickness and strength. The floor of the fourth ventricle was congested. The neck of the uterus was much enlarged and indurated. The left ovary was of the size of a large walnut, and was converted into a fibrous capsule containing dark fluid contents and one large clot. There was a cyst at the outer extremity of the left Fallopian tube.

The treatment of hysterical mania requires a careful adaptation to varying conditions. Its occasionally transitory nature justifies a trial of home-treatment before an asylum is resorted to; but if under home-treatment it remain unabated at the end of fourteen days, then removal should not be any longer delayed. The most protracted and troublesome cases that have fallen under my observation have been those in which home-treatment had been persevered in for months, until patience had been exhausted. The prolongation of the disease increases the risk of relapse, so that it is of much importance to cut it short at the earliest possible moment. During the maniacal condition there is not much room for moral treatment. A conciliatory and yet firm manner on the part of the physician, however, is not without its effect. Quietness and rest are also advantageous, and any simple occupation, such as sewing, if its adoption can be secured during an interval of tranquillity, is often very useful. It fixes attention, and by its very monotony soothes the perturbed mind. Exercise in the fresh air ought to be taken daily, and nourishing food must be administered. The medical treatment I generally begin with is a mixture containing bromide of potassium and tincture of valerian—forty grains of the former and a drachm of the latter in each dose, to be taken three or four times a day. This has sometimes a most gratifying effect, as in the case of A. H., who was perfectly well four days after her admission here. If, however, its beneficial action be not very speedily manifested, no good will result from continuing its employment. I should recom-

mend you, then, to resort to morphia and assafoetida. From a quarter to half a grain of the muriate of morphia with from ten to thirty grains of assafoetida may be given twice or thrice a day. The tincture of assafoetida is not objected to in pauper asylums. This treatment is generally successful; but should it fail, as it sometimes will, then cannabis Indica with bromide of potassium ought to be tried. This valuable combination was brought into notice in the *Annales Médico-Psychologiques* in 1867. We have employed it here constantly since then, and with decisive benefit in many cases. The use of narcotics is not contraindicated in hysterical mania. Warm, tepid, and even cold shower, baths are sometimes composing and useful. During convalescence, iron is almost always required, sometimes quinine also. I have a particularly high opinion of the value of Easton's syrup of the phosphates of iron, quinine, and strychnia, during recovery from hysterical mania. Of course, menstrual disorders must be subjected to their appropriate treatment.

## THE HASTINGS PRIZE ESSAY,

1870.

### ON DIGITALIS: ITS MODE OF ACTION AND ITS USE.\*

By J. MILNER FOTHERGILL, M.D.,

Late Senior Resident Medical Officer to the Public Dispensary, Leeds.

*Drugs of similar Power.*—The whole question of agents acting upon the heart so as to increase its power of contraction is comparatively new. With the exception of digitalis we are, generally speaking, scarcely acquainted with their names. The agents are either entirely new, or nothing has hitherto been known of their secondary effect upon the heart. The list of them is a short one, and will not take up much space in the enumeration. Thus Dr. Clifford Allbutt has advocated the use of Virginian cherry-juice (*Prunus Virginiana*) in cardiac affections; Dr. John Harley has investigated the action of belladonna; Dr. Braidwood the action of dajask, or arrow-poison of Borneo (*Tanghanina venenifera*); Drs. Hilton Fagge and Stevenson have investigated the action of the *Scilla maritima* and the *Helleborus viridis*; and Leven has investigated caffeine and thein. Of these, the writer has only experimented on digitalis, belladonna, and caffeine. There is thus plenty of opportunity for investigating further the action of these drugs, and adding to what we already know of their action; while there is a ground for hope that to this list may be added new agents more certain, more effective, and more manageable than those we as yet possess. It is, then, with the hope and expectation that such will be the case that the writer has devoted so large a space to the consideration of the mode of action of digitalis. He has striven to aggregate what is known of the subject, and his own more recent conclusions, in order that the question may be regarded as broadly as possible. The frequent digressions and the consideration of the action of the morbid process have sometimes been considered at greater length than the administration of the agent; as, once admitting the increase in the activity of the ventricular contraction as the chief therapeutic action of the agent, the question of the value of the agent must rest on the question as to how far increased ventricular contraction may or may not be beneficial. By thus treating digitalis as a member of a class of agents, it will much facilitate the investigation into the usefulness, or uselessness, of a drug as a cardiac neurotic. It is obvious that other agents which increase the ventricular contraction and bring the heart to a standstill in systole, must necessarily possess a therapeutic value allied to that of digitalis. In prosecuting such an inquiry, it will be easy to ascertain to what extent the action is common to that of the whole class, or in what it is singular. This grouping of agents as to action will assist us in aggregating a number of agents with either a primary or secondary effect upon the heart; in time this will constitute a group, and in practice the remote effect of an agent upon the heart will be taken into consideration in the choice of therapeutic agents. Thus, we as yet can merely guess to what extent the different actions of opium and belladonna, as hypnotics, may be dependent, as regards the success or non-success following their administration, on the vascularity of the brain. How far the beneficial effect of belladonna, at times when opium has failed to relieve, may rest directly, not on the different hypnotic alkaloid, but on the vascular supply of the brain being augmented by its use, we know not. Thus a series of experiments with belladonna in

\* Concluded from page 116 of last number.

delirium tremens, similar to those of Mr. Jones of Jersey with digitalis, when the pulse is feeble and fluttering, would be of the greatest practical interest. These might then be contrasted with a series with opium; and thus from a few facts we might attempt to build up a principle, and the application of that again to cases would in time furnish us with a law worth any amount of empirical guessing. It is only by the grouping of agents and then testing them by clinical experience and physiological experiment, observing the successes, the failures, and their causes, that we can expect to emerge from our present therapeutical chaos. Thus, under our old plan of empirical testing of agents, colchicum has six or eight (I forget which) times been removed in and out again of our *Pharmacopœia*. The same, to a less extent, has occurred to numerous other agents of no trifling activity. It is obvious that the use of these agents has been conducted on nothing approaching a law, else some definite conclusions one way or the other must have been arrived at. Without some definite idea of what it is we want exactly to attain, and by what action our agent is likely to achieve the desired result, we cannot be said to do anything more than—to use a vulgarism—"make shots." The experiments of Crum Brown and Frazer into the physiological and chemical agency of drugs, and Broadbent's valuable speculations on chemical tension, and the question of the retardation or aiding of oxidation as a mode of explaining the action of many agents, are steps in the right direction, the value of which we are scarcely yet in a position to correctly estimate. The advance of therapeutics hand in hand with increasing knowledge of physiological and pathological processes is much to be desired. It is scarcely cheering to find men who are teachers telling us that they have found rest in bed the only useful treatment in diseases of the heart. What, then, must become of those who must work or hunger? A hopeless therapeutical scepticism will never solve the problem how to enable those injured by rheumatic fever to be still useful members of the community. If rest in bed were all that modern medicine can do for these supplicants, many of them valuable lives, with good work in them, then we need not wonder at their regarding it as giving them a stone when they ask for bread, and at their trying hydropathy or homœopathy in sheer despair. The question is, how far can we not only enable them to live, but endow them with capacity to labour. This utilising a large number of lives which would otherwise be rendered inutile, is a problem which it is in the province of medicine to solve. That even with our present imperfect knowledge of these agents, much has been and is being done by numbers of enthusiastic workers at this field of inquiry, is unquestionable. In the present consideration of the mode of action of digitalis, the writer has striven so to arrange his materials as not only to elucidate the agency of it, but also to establish some broad rules applicable to the agents as a class, if once the action of the drug, as being capable of increasing ventricular contraction, be established. In order, then, to elucidate as far as possible this subject both particularly and generally, the action of morbid processes and the mode by which Nature proceeds to spontaneously repair them, or to compensate the lesions, have been subjected to critical review, and their indications recorded. The subject is one which must necessarily require great labour and pains to bring to anything like perfection, and anything written here must be considered as necessarily incomplete. The consideration of the question of increased ventricular contraction has been so conducted as neither to include nor exclude the question as to whether this group of agents are cardiac sedatives or tonics; in fact, it becomes more and more difficult to draw a distinction betwixt the two. The writer has thus striven to avoid all controversial inquiry on these heads, and by laying down the increased ventricular contraction as the action *par excellence* of digitalis, has striven so to conduct the investigation as not only to fix, to some extent at least, the action of the agent, and to demonstrate how it affects morbid conditions, but also to clear so much ground towards the successful investigation of allied agents, and the establishment of a new class of agents whose importance in the future we cannot estimate, but about the value of which we may at least be permitted to hope.

*Its Action in Nervous Affections.*—From the unquestionable benefit resulting from the administration of digitalis in some nervous affections, an impression has existed that it exercises a neurotic action, or to be more explicit, that it has some specific action over the nerve-centres. Like all powerful therapeutic agents, it has enjoyed an ephemeral reputation in the treatment of epilepsy; and from the undoubted influence it possesses over the vaso-motor system from the heart to the capillaries, it is conceivable enough that in some cases, its use was followed by benefit, but only it is improbable that it possesses any influence other than that it exerts over the circulation. Serré used Debout's pill, consisting of four-fifths of a grain of digitalis, and one grain and a half of quinine, in the treatment of hemiplegia, continuing it for long periods together. The success which followed the treatment was greatly influ-

enced no doubt by the quinine; in fact, it is difficult to rid oneself of the impression that the quinine had the most to do with the result. Lockhart Robertson found that in certain cases of maniacal excitement in general paresis of the insane, its use was attended with marked benefit. He states: "It acts in every case of the kind in which I have given it as a specific, calming the excitement, and enabling the patient to pass without wear or irritation through this stage of the malady. Its action has been to steady the pulse, and thus apparently to supply the brain better with blood, and so obviate the tendency then existing to effusion of serum."

*In Delirium Tremens.*—The use of digitalis in heroic doses by Mr. Jones, of Jersey, with marked success, is one of the extraordinary facts of therapeutics. The administration of the tincture in half-ounce doses, and repeated, too, at short intervals of time, was found to exercise an action that was almost amazing in delirium tremens. It was attempted to make out that this was due to the half ounce of proof spirit; but that was simply preposterous. The amount of digitalis in four drachms of the tincture must have exercised an influence of some kind. Neither has it been found universally successful in attaining the desired result. From personal experience, I may state that it is when the pulse is compressible, rapid, fluttering—in fact, when there is evidence of cardiac distension accompanied by great nervous prostration, that its administration is followed by beneficial results. The condition of the brain is one of anæmia from cardiac feebleness; while that feebleness is no doubt occasioned by the exhaustion of nerve-force, by the continued administration of the alcoholic stimulus. The sympathetic is exhausted, and cardiac distension follows; from that, again, imperfect circulation and cerebral anæmia; the exhausted brain is deprived of its blood-supply to a great extent; less and less nerve-force is evolved; the sympathetic is still further enfeebled; and the condition of a complex cerebral anæmia, called delirium tremens, ensues. The administration of digitalis in heroic doses produces a decided effect on the circulation, and that, again, relieves the brain, in a manner strictly analogous to that described above by Dr. Lockhart Robertson. When the pulse is full and sustained, and there is no great prostration, its use is not followed by any desirable result.

*In Anæmia of the Brain.*—In some conditions of cerebral anæmia dependent on disease at the aortic valves, digitalis exercises a decided beneficial action; so much so, indeed, that it is easily conceivable that it might be regarded as a nervine tonic. In speaking of anæmic conditions of the brain, Todd, in his *Cyclopædia*, Art. Abnormal Anatomy of Nerve-Centres, states—"It is also present when the heart, oppressed by some disease affecting its own structure, fails to propel the blood with its proper force into the brain." A most interesting instance of this has fallen under my own notice. An old and visibly feeble lady of 70, was subject to attacks coming on suddenly, during which she fell, but did not lose consciousness. This at once cleared away any suspicion of epilepsy, and suggested the condition of acute cerebral anæmia. That is, the supply of blood to the brain became so interfered with, that the brain was unable to evolve the normal amount of nerve-force, and the patient fell just as in swooning; in fact, it was syncope. The falling thus took off the weight of the blood-column above the heart, and thus gave relief to it; while at the same time, the head falling as low as any other part, the blood gravitated into it as readily as into the rest of the body. There was aortic obstruction, and, after some careful watching, it became apparent that the attacks came on whenever there was any approach to exhaustion, either from physical or mental effort. That is, the amount of blood passing out of the narrowed outlet was sufficient to maintain a species of integrity of nerve-manifestation for the wants of the system when all was quiet; but exertion, by overtaking the power of the heart, led to anæmia of the organ placed highest up in the organism; and then the fall, by restoring the circulation through the encephalon, and permitting to the heart a period of comparative rest, comes to the rescue and allows of readjustment. The administration of digitalis and consequent improvement of the heart's action, invariably gave her relief, and enabled her to undergo more exertion without the attacks of syncope, and relieved her from them when recurring after any exhaustion. The period of benefit lasted for some time—in fact, as long as any evidence of its action on the heart remained. The beneficial effect of its use in cerebral affections can only, I believe, be explained after this fashion. Cerebral disorder is frequently due to cardiac disease; and when it is so related, and the nervous affection can be regarded as a sequel to the cardiac impairment, whether to persistent disease or debility referable to passing circumstances—when the head-symptoms can be clearly attributed to failure in the heart's power of blood-propulsion—then the administration of digitalis may fairly be calculated upon to be beneficial. When cerebral anæmia has a cardiac origin, then, and then only, I believe that digitalis is of service.

*Is Digitalis a Diuretic?*—If by a diuretic is meant an agent eliminated by the kidneys, and producing increased secretion in the true sense of the word, then certainly digitalis is not a diuretic. If by a diuretic is meant an agent which increases the renal secretion by some special action, as juniper or cantharides, irrespective of an alteration in the arterial tension, digitalis can lay no claim to the appellation. Digitalis is not a true diuretic, though perhaps no material in the *Pharmacopœia* produces such decided increase in the renal flow as it does; but only under certain conditions. An alteration in the blood-pressure on the glomeruli of the kidney affects the flow; if that pressure be decreased, as in advanced cardiac disease, with enfeebled circulation, then a small quantity of urine is passed. If that pressure be increased, no matter how, increased flow follows. Thus, for instance, a large imbibition of water, by passing into the circulation and producing increased pressure on the glomeruli, will soon affect the renal flow unless some other excretory organ be very active. When the skin is acting freely, and a large quantity of blood is located in the vessels of the skin, a sudden cooling of the skin is followed by diuresis, the cold contracting the cuticular vessels, and thus driving the blood internally, and increasing the pressure on the vessels of the viscera. Interstitial nephritis or cirrhosis of the kidney acts as a diuretic in the same manner. So much of the structure of the kidney is destroyed for all useful purposes; and therefore, as no diminution takes place in the calibre of the renal artery, there is increased pressure on the remaining uninjured portion, and thus there ensues increased diuresis—one of the prominent early symptoms of cirrhotic kidney. So, also, the flow of limpid urine in hysteria. We know that in hysteria there is a diminution of the calibre of the arteries, due to derangement of the vaso-motor system, and accompanied by increased action of the heart to overcome that condition, so much so as often to bring out palpitation; thus the pressure is again increased, and diuresis follows. But these conditions, though producing an increase in the renal flow, are not true diuretics. Digitalis in a similar manner acts as a diuretic in enfeebled conditions of the circulation, by increasing the arterial tension, as described in a preceding section. When administered to people in health, it does not increase the flow of urine proper—that is, of salts as well as water. Stadion put himself upon a strict diet, and took digitaline, and his urine was diminished. Winogradoff gave digitaline to several persons for five days, and found no results, except in one, and then there was diminution. Brunton, who experimented on himself freely, found increased diuresis; but on the day marked "intoxication", there was a distinct fall. The case of poisoning related by him illustrates the effect of digitalis well. He says: "The amount of urine in my own case was markedly diminished during the period of intoxication, when the gastrointestinal canal was most affected; and in the case of Daniel G., when the pulse was most affected, it fell from an average of between 40 and 50 ounces to 30 ounces on December 2nd, 25 and 26 ounces on the 3rd and 4th, and 18 ounces on the 5th and 6th; again slowly rising, till on the 10th it rose from 25 to 44 ounces, and then remained at its normal standard." Christison and Mazel both noticed suppression in cases of poisoning by it. Boubly and Reynal found a temporary suppression in the horses experimented on by them. In fact, when digitalis is producing those symptoms of intoxication which accompany a too firmly closed ventricle, a diminution in the flow of urine is one symptom. Now then that is merely again a question of arterial tension. If a small quantity of blood only be thrown into the aorta at each ventricular systole, it makes no difference whether it be due to a state of over-contraction and imperfect distension of the ventricle, or to an imperfect systole. The effect is the same, whether due to the imperfect contraction of distension, or to the imperfect dilatation in the unnaturally contracted condition of the ventricle, which takes its rise in the excessive administration of digitalis. When the digitalis is given beyond the point of maximum, arterial tension resulting, then the urine is diminished in quantity; the flow and the arterial tension being indissoluble. Thus, when given in cardiac disease, when an imperfect systole does not produce arterial tension, it increases the flow of urine which had previously been defective. When administered to poisoning, even total suppression may follow. In fact, my opinion is identical with that of Dr. Germaine: "there is no proof that digitalis possesses diuretic properties, the reputation conferred upon it to this effect by Withering having been accepted without discussion; and the diuresis which often follows when an amelioration of the condition of the circulation has been produced by it in organic disease of the heart, is only a mediate effect, resulting from the return of the circulation to its normal condition." On the other hand, the flow of urine following its administration in enfeebled conditions of the heart, is so affected as to be, in one case at least the writer knows of, in itself to be a source of danger.

*The Use of Digitalis.*—Like other vegetable substances, digitalis is prepared for use by either tincture, infusion, extract, or separation of the

active principle digitaline. The extract is little used, and personally I know nothing about it. The tincture is the most convenient form ordinarily, but throws down a dark green precipitate with iron, which detracts from its desirability. For general use, it can be given along with the ammonio-citrate of iron, or, still better, the potassio-tartrate. It is better kept in a dark cupboard or wrapped in a dark coloured paper, as light is supposed to act deleteriously upon it, weakening it and lowering its activity. The infusion is a good preparation for use along with potash or diuretics, and is conveniently added to vegetable infusions. Digitaline in solution may be the most elegant form, and perhaps may be found ultimately to be the most exact form for accurate administration; but a strong impression against it was left on my mind from experiments on frogs, when a solution of digitaline did certainly not produce such a decided effect as the tincture upon the ventricular contractions. It is certainly possible that the other constituents, digitalose, digitalic acid, etc., may possess properties peculiar to themselves; and when the importance of a knowledge of the action of different agents on the heart-walls becomes fully recognised—for as yet we are only on the threshold of the inquiry—a careful investigation of them may not be barren in results. This field of inquiry is a most promising one; and no more important addition could be made to the present usefulness of medicine than a perfect knowledge of the action of agents on the heart, either in the chronic condition of persistent alteration—either as a primary or secondary lesion, or in passing conditions. We have long been acquainted with the frequency with which cases occur when, in chronic disease, the question of the integrity of the muscular walls of the heart, or of structural change in them, guides our prognosis as to how long the struggle may be maintained. We are, too, gradually recognising the failure of the right side of the heart in asthenic disease or affections of the respiratory organs, as the channel through which death commonly approaches; we can calculate how certainly the right ventricle, taxed to the utmost, becomes gradually paralysed by the carbonic acid of its contained blood anæsthetising its action. If we can find means to keep up its action, we may tide that patient on to recovery; while in the present state of our knowledge, the condition is only recognised by a few, and the means of producing any impression upon the condition by therapeutic agents confined to the hopefulness of only a very few. In the treatment of chronic conditions, when it is necessary to keep up the administration of digitalis until structural changes are produced, perhaps the powdered leaves are the most desirable form. In this form, it can be given in pill with the dried sulphate of iron, carminatives, laxatives, or both, and in this form will keep some time, and can be given twice a day without causing the patients to revolt at its nauseous taste, or creating any aversion, on æsthetic principles, to its muddy-looking combination with iron. For long, a favourite form of pill with me for persistent use has been a combination of half a grain to a grain of powdered digitalis, with an equal quantity of the dried sulphate of iron in powder, and a morsel of cayenne, in extract of gentian, or aloes and myrrh pill. Thus we secure at one cast an action on the circulation, the addition of iron in a form which will act locally on the stomach, and thus act as an astringent in the gastric catarrh so common among the sufferers from heart-disease; while the carminative action of the cayenne is useful, and also takes off the griping from the action of the laxative, when an action is also necessary, as is commonly the case, on the bowels. I have had patients for months, and in some cases even years, thus under its influence in the most satisfactory manner. With their box of pills they can go anywhere, can take them about, and have a reserve stock if necessary; and then, twice a day or so, a pill can be taken without any inconvenience or parade of medicine-taking. One point of some importance must not be forgotten in this mode of its use, viz., that the pill must be taken shortly after food, otherwise it may be pouched in a fold of the stomach, and lie dormant, or it may be passed at once into the bowels, and its good effects lost. The pill is an artistic application of scientific research to the food, and must be regarded as such essentially, as, in fact, must all restorative remedies. In the use of digitalis, the addition of iron is of great importance. Some may raise objections that the good effect is due solely to the iron; but surely the constant administration of so potent an agent as digitalis cannot be without some effect. The results thus attained appear too early to be the mere effect of the iron. While the attempt to produce better nutrition of the heart from its use, as we saw in a preceding section, does actually succeed, the addition of iron, from its hæmatic properties, aids us most materially. From the cheering results which I have witnessed in numerous cases of chronic cardiac disease, and the great alteration effected in the patient's condition, both as regards comfort, or, rather, relief from discomfort, ability to take more exercise, and even to undergo more exertion in those cases where the patient's circumstances necessitated labour, I can urge most honestly and conscientiously its use, and especially in this combination.

Another application of it is very important, and that is its absorption through the skin. In many instances, it is desirable to bring out the action of the digitalis when the risk of disordering the stomach may act as a check, or even when there is already great gastric disturbance. Here it may be used by either poultices of the leaves, or flannels soaked in the infusion, or a mixture of the tincture and water applied to the abdomen and thighs. Cases are given by Christison of such use of it. Trousseau relates a very interesting case where very decided results were thus obtained (vol. i, chap. xxxv). Some cases were recently detailed in the journals of such use of it. This manner of administering digitalis should never be lost sight of, as it may now and then enable us to do what we cannot accomplish by the mouth.

Hypodermic injection is another mode of administering it which should not be overlooked. Certainly, in the experiments on frogs, this was chiefly resorted to on account of its convenience. Bouillaud pursued an endemic treatment by dusting a blister over the heart, with from six to fifteen grains of powdered digitalis. These various modes of administering digitalis have each their advantages according to peculiar circumstances. No one plan of action must bind the practitioner's mind in fetters. He must be ready and willing to use each in its place, or even to substitute for digitalis some drug of similar action. From the known intolerance of mercury in some constitutions, and notably in those suffering from cirrhosis of the kidney, which is often followed by consequent heart-mischief, with its train of sequelæ, the old combination of digitalis, squill, and blue pill may have to be abandoned, and for the blue pill iodide of potassium substituted. Patients' prejudices, as well as their needs, must be consulted. It is much to be desired that some drug may be discovered with equal properties to digitalis, and about whose action no preconceived opinions, based on imperfect observation, may bias the minds of medical men. It would be easier to establish the use of such an agent especially in this experimental age, than to war against a settled impression. And though at present the list of agents possessing an action on the heart, and through it a control over the circulation, may be a very limited one, but at the same time very important, the day is not far distant when the importance of inquiry in this direction will make itself felt. I have not claimed for digitalis anything for which it cannot fairly substantiate its claim, nor have I accorded to it any mystical action, differing from that of any other therapeutic agent. I have striven, as far as possible, to exercise the functions of a judge, as well as of an advocate, and tried fairly to lay down what, in the present state of our knowledge, digitalis can do, and what it cannot. And I am quite willing to labour under the disadvantage of being regarded as an enthusiast, if only the subject can get that attention paid to it that it deserves; and my experience tells me in language that is unmisakeable, that the effect of agents upon the heart, of which digitalis is the most powerful one with which we are yet acquainted, can no longer be overlooked by any one in the profession who regards either his own interests or those of his patients.

## TELEOLOGY AND EVOLUTION.

BY THE

REV. SAMUEL HAUGHTON, M.D. Dubl., D.C.L. Oxon., F.R.S.  
Fellow of Trinity College, Dublin.

WITH permission, I shall take advantage of the opportunity offered by Dr. T. Clifford Allbutt's letter of the 12th instant, published in the BRITISH MEDICAL JOURNAL of the 15th instant, to make a few brief remarks on Teleology and Evolution.

There is no necessary opposition between these expressions; and it is quite possible, perhaps even probable, that Teleology works out its purpose by means of Evolution. If the Evolution be the result of foresight and contrivance, it becomes merely the expression of the chain of Second Causes by means of which the purposes of the great First Cause are harmoniously carried out. But if, on the other hand, Evolution admit of chance combinations, capable of becoming permanent, and not foreseen, then it is irreconcilable with the fundamental hypothesis of Teleology.

Dr. Allbutt has, I believe, correctly interpreted what I intended to show in my occasional references to Teleology during my lectures on the Principle of Least Action. I illustrated this principle by means of the limbs of the tiger and the wing of the albatross, and endeavoured to show that the several conditions which combine to produce the action of those members are so related to each other as to fulfil the requirements of the principle of Least Action; or, in other words, that these conditions are so related to each other that, if all of them

save one be given, we can calculate with certainty the remaining condition.

This remarkable fact is, in my judgment, irreconcilable with the hypothesis of Evolution, by means of slow variation of the conditions, which is the fundamental idea of Mr. Darwin's hypothesis.

Let us suppose, in fact, that the exercise of any complex organ of an animal depends upon a certain number of conditions, which we may call  $a, b, c$ , etc.; then the result may be expressed as a function of those conditions,

$$F(a, b, c, \text{etc.}, x, y, z).$$

The principle of Least Action requires this function to be a maximum, which will be the case for certain definite groups of values of the elementary conditions on which the complex function depends, and for no others. We shall, therefore, have the principle of Least Action fulfilled for certain groups of values.

$$F(a, b, c, \text{etc.}, x, y, z).$$

$$F'(a', b', c', \text{etc.}, x', y', z'). \text{—And so on.}$$

I showed in my lectures that, if certain conditions,  $a, b, c$ , etc., be given, the other unknown conditions,  $x, y, z$ , can be calculated on the hypothesis of Least Action; and I verified this statement by several remarkable examples. We may therefore consider it as proved, or at least admitted, that the existing arrangements of Nature fulfil the conditions imposed by the principle of Least Action. This admission is fatal to the hypothesis of Evolution by slow variation. For, let us suppose the two functions  $F$  and  $F'$  each to satisfy the conditions of Least Action, each of these will represent a complex result which is stable, and which will refuse to vary indefinitely from its original value. Let the quantities  $x, y, z$ , etc., vary by slow degrees in any direction whatever, I assert that the principle of Least Action, which requires the function  $F$  to be a maximum, will prevent  $x, y, z$  from varying indefinitely; or, in other words, that the controlling influence of the remaining conditions,  $a, b, c$ , etc., will compel  $x, y, z$  to return back to their original values; which values, in conjunction with those of  $a, b, c$ , etc., rendered the function  $F$  a maximum. In like manner,  $F'$  is another maximum; and its elements,  $a', b', \dots, x', y'$ , etc., cannot vary indefinitely by slow degrees.

The conditions involved in  $F$  and  $F'$  are each stable; and, when variations of small extent occur, there is a necessary return to the condition  $F$ , or  $F'$ , which involves the maximum effect; but it is absolutely impossible for  $F$  to be transformed into  $F'$  by slow variations of its elements, without losing that property of being a maximum on which its continued existence depends.

The function  $F$  is a maximum only for certain definite, and often far removed, groups of values of  $a, b, c$ , etc.,  $x, y, z$ ; and we cannot transform  $F$  into  $F'$  without making the hypothesis of abrupt changes in the values of the elements, for any small slow changes will reproduce  $F$  again and again.

The force of this argument will remain unchanged, if by  $F$  and  $F'$  we mean two species, instead of two arrangements of organs.

An illustration from physical astronomy will clear up this point. If there were only one planet revolving round the sun, it would describe an ellipse which would remain the same at each revolution; but, as there are several planets, each exerting a small disturbing force, the planet describes an ellipse which differs slightly at each revolution from its predecessor and from its successor. Still the path is always an ellipse, and never shows any tendency to become an hyperbola or parabola, for the simple reason that all its elements change slowly. Let us now, however, take the case of a comet, moving in an hyperbolic path round the sun, and coming into close proximity to a large planet: the elements of the comet's path,  $a, b, c$ , etc., are now abruptly changed, and we find the hyperbolic path changed in a few hours into an ellipse.

The Evolution of one species from another must, in my opinion, be the result of sudden, not of gradual, changes of conditions; and no scientific attempt has as yet been made to show how such evolution of species may take place.

The concluding portion of Dr. Allbutt's letter, respecting the *surplusage* of force sometimes found in Nature, opens up a subject of discussion on which I could say much, were I not afraid to weary by my much writing, as I have already offended some by my much talking.

In conclusion, I would remark that, in the supposed slow passage of an organ or species from the maximum  $F$  to another maximum  $F'$ , it must necessarily pass through a minimum, which will exhibit in an extreme degree want of contrivance and imperfection. Where are these imperfections? They ought vastly to exceed in number the perfect types which have reached the maximum effect. Where is the evidence of the endless succession of blunders which blind Nature has used as stepping-stones to produce her few happy successes? I cannot find them either in living nature or in the records of palæontology.

## DYNAMICS OF NERVE AND MUSCLE.

BY CHARLES B. RADCLIFFE, M.D., F.R.C.P.,

Physician to the Westminster Hospital, and to the National Hospital for the Paralysed and Epileptic.

IN the article in last week's JOURNAL, in which my recent book entitled *Dynamics of Nerve and Muscle* is taken as the text, certain conclusions are drawn which ought not, as it seems to me, to be allowed to pass unchallenged.

The gist of the article is to object to a part of a theory of animal electricity which in substance is simply this—that the walls of the fibres and cells of living muscle and nerve-tissue during rest are charged in the way in which Leyden jars are charged, and that this charge is discharged during action, the discharge being analogous to that of the torpedo. It is argued that these walls are sufficiently bad conductors to justify the conclusion that they may act as dielectrics; it is argued that a charge of one kind of electricity may originate in the molecular reactions connected with nutrition and respiration, and that the development of the charge upon one surface of these dielectric walls may induce a charge of the other kind of electricity upon the other surface; and the opposite electrical condition of the sides and ends of the fibres are accounted for by supposing that the sides correspond to the outer charged surface, and the ends to the inner charged surface of the walls—the charge of the latter surface being conducted to the ends by the contents of the fibres. This in substance is the view to which exception is taken, and for which I am still disposed to do battle.

What may be regarded as the starting-point in my theorising is conceded, namely, this, that certain animal tissues—the sarcolemma and neurilemma in particular—are bad enough conductors to be capable of acting as dielectrics; and also this, that the electrical phenomena of living nerve and voluntary muscle during rest may be accounted for on the supposition that the neurilemma and sarcolemma are then in the predicament of charged Leyden jars. But it is objected that this view cannot apply to involuntary muscles of which the fibres are without sarcolemma; and it is further urged that the explanation given of the method of charging the fibres of nerve and muscle may be called in question, and that the discharge is taken for granted without sufficient proof of its existence. Objections are indeed raised which cannot be disregarded, and to which I therefore address myself *seriatim*, merely premising that I have lately made many new measurements of the resistance of animal tissues to electrical conduction, which show that this resistance, instead of being overrated, has been greatly underrated; that all soft animal tissues, when dry, really become insulators; and that perfectly fresh yellow elastic tissue, which enters largely into the composition of both sarcolemma and neurilemma, is a very bad conductor—the worst of all the animal tissues, apparently.

The objection that the Leyden jar hypothesis cannot apply to the fibres of involuntary muscle appears, at first sight, to have considerable weight in it. These fibres consist of a number of contractile cells, imbedded in an amorphous transparent substance. They have no proper sheath or sarcolemma like the fibres of voluntary muscle. But what of this? The cells, there is every reason to believe, are the contractile part of the fibre. Their walls, in the opinion of many, take the place of the sarcolemma, being in fact analogous to the sarcolemma; and certainly there is no reason why the contents of these cells should not be regarded as analogous to the contents of the sarcolemma. In point of fact, there is no good reason why these walls, if there be any walls, together with the amorphous transparent substance of the fibre outside them, should not be a crude, thick, less elaborated sarcolemma. Thick or thin walls will equally serve my purpose, provided they have the requisite non-conductibility to enable them to act as dielectrics. Nor need this view be looked upon as at all far-fetched; for it must be borne in mind that in many long voluntary muscles the fibres do not run through the muscle from end to end, but are made up of several fusiform fibres, overlapping more or less at their ends, and so really copying, in a sense, the arrangement of separate contractile cells, which is met with in certain involuntary muscular fibres. Hence, after all, there need be no structural difficulty in supposing that the living fibres of involuntary muscles, like the living fibres of voluntary muscle, may, during rest, be charged like Leyden jars, as the theory supposes.

The next objection, which concerns the explanation I have offered of the way in which the fibres are charged, is only hinted at, but it must not be passed by without notice. I have said that this charge may have its origin in certain molecular reactions outside the walls of the fibres and cells: in the article under consideration it is hinted that this charging is as likely—nay, more likely—to happen from the inside. And so say I now. Indeed, for some time past I have held, as several per-

sons can testify, that the more probable view of the charging is this: 1. That the granular or fibrilliform substance within the fibres and cells, which substance represents more or less unchanged protoplasm, receives food and air, feeds and breathes, from without, not through every part of the walls, but only at the points occupied by the nuclei, which nuclei, indeed, may represent so much more or less unchanged protoplasm; 2. That an electrical charge is developed upon the inner surface of the walls by the molecular changes in the contents of the fibres and cells, which changes are brought about by nutrition and respiration—the opposite charge, which is not wanted, escaping to earth by the same opening, or openings, through which the fluids having to do with respiration and nutrition found entrance; and, 3. That in this way the walls of the fibres or cells are charged from within to without, the charge on the inner surface inducing through the dielectric walls the opposite charge on the outer surface of the walls. Either view is possible; but this view is, as it seems to me, not only simpler, but it also disposes of a difficulty which has been started elsewhere; namely, this, that I do not provide the conducting surfaces of the dielectric walls which are necessary to the charging on the Leyden-jar hypothesis; for it is manifest that the inner surface of the walls, whether this be a conductor or an insulator, will be charged by being directly in contact with the substance in the molecular reaction of which the charge originates; and that in this way the outer surface will be charged also, for, if one surface be charged, induction will secure the charging of the other surface, be that other surface a conductor or an insulator.

Nor do I consent to the statement that I have failed to supply sufficient proof of the discharge during action, for which I contend. In proof of this discharge I argued, along with Matteucci, from certain striking anatomical and physiological analogies between the muscular and electrical apparatus of the torpedo, and from the phenomenon of secondary or induced muscular action which Matteucci discovered; and I supported this argument by appealing to the parallel phenomenon of secondary or induced nervous action discovered by Du Bois-Reymond; and this argument, as it still appears to me, is perfectly valid.

In proof of this discharge, I instanced also the more or less complete disappearance of the muscle-current in muscular action, and of the nerve-current in nervous action—the great facts discovered by Du Bois-Reymond; and I argued that this disappearance may be a proof of the discharge of which Matteucci had inferred the existence from analogy; and these facts, as I take it, still justify this conclusion.

In proof of this discharge, I also showed—a fact which I have myself made out for the first time by means of Sir William Thomson's new quadrant electrometer—that in both nerve and muscle there is a disappearance more or less complete during action of the electrical charge demonstrably present during rest: and I argued, as I still do, that this is the very *experimentum crucis* of discharge, the instrument taking cognisance only, not of changes of current, but of the simple facts of charge and discharge.

In physiological matters, proof no doubt must always be more or less a matter of probability; but surely there must be here a fair amount of proof, not only that action in nerve and muscle may be accompanied by discharge of electricity, but also that this discharge is analogous to that of the torpedo!

What, then? Is this view of which I have been speaking, or that of Du Bois-Reymond, the more probable?

The primary electrical condition of nerve and muscle, according to Du Bois-Reymond, is not static, but current. The nerve and muscle are made up of what this physiologist has called *peripolar* molecules—molecules negative at the two poles and positive at the equator, or *vice versa*; and the nerve-current and muscle-current are derived portions of infinitely stronger currents ever circulating in closed circuits around the peripolar molecules. How these primary currents are kept up—how, that is, the two opposite electricities are separated and kept apart in the peripolar molecules—is not explained; how the weakening of the nerve-current and muscle-current, which happens in the action of nerve and muscle, is brought about, is not accounted for. The theory is incomplete in these respects; but this, perhaps, is of less moment, for no physiological work is supposed to be done by the electricity. On the other hand, there is nothing in the view of which I have been speaking which is not readily grasped by the imagination, and which does not as readily tally with the facts. In this view, the non-conducting properties of certain parts of the tissues, which are difficulties in the way of accepting the current-view, find their *raison d'être*. On this view, the disappearance of electricity during action in nerve and muscle, which is not accounted for on the current view, has its explanation, for it is only the sign of the discharge of the charge present during rest. On this view, the existence as well as the separation of the two opposite electricities in the fibres, which is not accounted for on the current view, is also explained, for the clue is simply the theory of the Leyden jar. And,

moreover, as I have endeavoured to show in the book supplying the text to the article upon which I am commenting, important consequences flow out of this theory, which consequences are themselves strong arguments in favour of the probability of this theory—consequences which show that electricity, instead of being a mere accident, may be an all-important agent in vital phenomena, an agent in many cases doing work which has been wrongly attributed to life.

The subject, no doubt, is difficult enough, but its difficulties, in the main, disappear when once the threshold of the inquiry is crossed; and my object at present is to ask my readers not to be deterred from entering by any terrors connected with the "dweller on the threshold", but to enter boldly, and then to do me the justice to weigh my argument as a whole, and not in part, and to reserve their judgment until they can find time to read what I have myself written on the subject.

## EXPERIMENTS WITH CARBOLIC ACID.

By ANGUS MACKINTOSH, M.D., Callington.

IN the interest of science, as bearing specially on the effects of carbolic acid on organic substances, I desire to record a few experiments, with their results, which I carefully performed with carbolic acid in November last, with the view of proving further to my own satisfaction certain chemical and physiological changes that I have observed in treating ulcers and severe surgical injuries with the acid. The results at which I arrived were published last year; and, in consequence, Messrs. F. C. Calvert and Co., the well known chemists of Manchester, kindly forwarded to me several samples of the different preparations made by them, to be tried in small-pox, etc. I have now tested them in many cases of small-pox with almost unparalleled success, and also in various surgical operations; and, in justice to Messrs. Calvert and Co., must say that I consider their preparations immensely superior to any other of the acid yet given to the profession.

Having had reasons for years to question the accuracy and correctness of the germ-theory of disease, and of the *modus operandi* of the antiseptic system of treatment, so ably brought before the profession by my respected teacher, Professor Lister, I last year called the attention of the profession to the fact that the beneficial effects of carbolic acid on wounds, etc., were not to be attributed solely to the destruction of atmospheric germs, but mainly, if not completely, to the chemical and stimulating effects of it on the constituents of the blood and surrounding parts. The following experiments confirm the opinion then expressed.

**CLASS I. Experiment I.**—On November 8th, 1870, I mixed a quarter of a pound of bullock's blood (fresh) with two ounces of F. C. Calvert and Co.'s carbolic acid No. 5 (proportion, 10 of water to 1 acid), and covered the whole so as to admit no air. The temperature was 50 deg. *Result*, July 10th, 1871: No signs of putrefaction.

**Experiment II.**—On November 8th, 1870, I mixed a quarter of a pound of bullock's blood (fresh) with two ounces of Calvert's carbolic acid No. 5 (proportion, 10 of water to 1 acid), and left the whole uncovered and exposed to the air. The vessels used in this and the previous experiment were placed side by side in the same apartment. *Result*, July 10th, 1871: Not the slightest signs of or tendency to putrefaction.

**Experiment III.**—On November 9th, 1870, I weighed two ounces of lean fresh beef, and placed it in a pot with two ounces of carbolic acid (Calvert's No. 5, 10 water to 1 acid), and covered the contents completely from the atmosphere. *Result*, July 12th, 1871: The meat was perfectly free from putrefaction.

**Experiment IV.**—On November 9th, 1870, I weighed two ounces of lean fresh beef, and placed it in a pot with two ounces of carbolic acid (Calvert's No. 5, 10 water to 1 acid), and left the contents exposed to the air in the same apartment with Nos. 1, 2, and 3. *Result*, July 10th, 1871: There was no offensive odour nor putrefaction.

**CLASS II. Experiment V.**—In January 1871, I excised from a man's left arm a non-malignant tumour weighing a pound and a half, and dressed the wound with thin muslin and Calvert's carbolic acid No. 5 (proportion, 30 of water to 1 of acid). The acid solution was dropped freely over the muslin many times during the day. The wound healed without suppuration or putrefaction.

**Experiment VI.**—I amputated an old man's middle finger in April 1871, and dressed it in the same way as No. 5, with thin muslin, dropping the acid solution freely over the muslin several times throughout the day. The result was a perfect cicatrix, without any appearance of pus, suppuration, or putrefaction.

**Experiment VII.**—A miner had both arms and face burnt in consequence of an explosion whilst blasting. The face was treated with linseed-oil and linseed-meal poultices, and afterwards with oxide of zinc

ointment. A small quantity of pus could be detected. The arms were treated with carbolic acid and linseed-oil, 1 to 20. The muslin (the only covering) was always kept wet with the oil and acid. The result was a complete cure, without any pus or putrefaction.

These experiments, in combination with those which I published last year, have completely convinced me that the detailed plan of dressing wounds recommended by Professor Lister is absolutely unnecessary for the object of healing wounds by the first intention or without the formation of pus; and that the germ-theory of disease is, correctly speaking, an error.

In the first class of these experiments, I treated the blood and beef with exactly the same quantity of the acid solution, in the same proportion; and sealed one so as to exclude the contents completely from the atmosphere, and left the other exposed to the atmosphere. Under these opposite conditions, both, in the course of eight months, presented almost the same appearance, and no appreciable distinction could be recognised between their odours. There were no marks or signs of putrefaction in either.

The second class of experiments also gave the same result, and shows that only careful attention and regular application are required to produce always similar effects. I used the muslin cloth, so as to allow a free current of air to all parts of the wounds. I firmly believe that the real difference in healing with or without suppuration is chiefly, if not altogether, owing to regularity in the application; and that the beneficial effects of the acid are to be principally attributed to its chemical and stimulating influence on the constituents of the blood and other parts concerned.

## NOTES ON THE TREATMENT OF INSANE PATIENTS IN PRIVATE PRACTICE.\*

By D. YELLOWLEES, M.D., Medical Superintendent of the Glamorgan County Asylum.

IF we could obtain prophetic knowledge as to the effects of remedies, or could understand a case as fully at its commencement as after we had watched its progress, this unattainable knowledge would often modify our treatment. Possessing unusual opportunities for observing insanity in all its phases, and for watching the progress of cases of which others have seen only the commencement, it has occurred to me that this special experience, in so far as it relates to home-treatment, might be usefully summarised. I hope no one will construe my remarks as reflecting on the treatment of others, or will suppose that I wish to assume the office of an instructor: nothing can be further from my intention. I know well the extreme difficulty—often the impossibility—of properly carrying out the treatment of the insane at their own homes; and it is with a view to lessen, if possible, this difficulty, that I submit the following notes.

Insane patients treated at home are apt to get—

1. *Too much narcotic medicine and too little general treatment.* This is often the case, and very naturally. The mental excitement is the most prominent symptom, the one which most alarms the friends, and for the abatement of which they are supremely anxious. Even to the practitioner, the brain-disturbance is apt to eclipse the other symptoms, and to receive undue or almost exclusive attention; whereas treatment may be urgently required for the amenorrhoea, the dyspepsia, the constipation, or other coexisting disorder, of which the brain-disturbance is probably in great measure a result. Relieving a sluggish liver, or restoring the functions of a neglected skin, often allays excitement better than any quantity of sedatives. When sedatives are necessary—and they are often most necessary and beneficial—chloral hydrate, bromide of potassium, or bromide with cannabis Indica, should generally be first used; they often answer admirably, and the injurious general effects of more direct narcotics are avoided. I am satisfied that the recovery of curable cases has often been retarded, and the condition of hopeless cases aggravated, by the undue use of opium. On the other hand, it is often of great value.

2. *Too much depression and too little support.* This is a frequent phase of home-treatment. Antimony, alone or with morphia, is often a favourite remedy; and the friends are always anxious to aid in keeping the patient low. This may, perhaps, be wise treatment in some cases; but it is very certain that brain-excitement is usually a result of *asthenia*, and requires support far oftener than depression. I know no form of excitement that is aggravated by an ample supply of the most nourishing and wholesome food. In every case it is an essential element of proper treatment, and in many cases a liberal addition of stimulants is the best sedative we can use.

\* Read at the annual meeting of the South Wales and Monmouthshire Branch, July 5th.

3. *Too much confinement and too little open-air exercise.* This constitutes a drawback almost inseparable from home-treatment, so great and so obvious that I need only mention it. A most important means of restoration is wanting when the patient cannot get out of doors, and has nothing on which to fix his attention or expend his energies beyond the limits of his room.

These unfavourable conditions are rendered still more so by—

4. *Too much interference and too little tact* on the part of those around the patient. If he be apprehensive, dejected, or terror-stricken, he is harassed by attentions and services which he wholly misinterprets, and which only aggravate his distress. If he be irritable, defiant, or dangerous, he is coaxed, deceived, or threatened, as seems best to serve the purpose at the time; and, if he be thus goaded into violence, or driven to it by delusions and the utter *ennui* of close confinement, the only notion of management usually entertained by friends is to overpower him by sheer force and tie him to the bedstead—the omnipotent influence of calmness, truthfulness, patience, and non-resistance, being unknown or untried.

I anticipate, of course, the reply to all this: that such evils, or most of them, are inevitable in the treatment of lunatics at home. I answer that, where such evils are really inevitable, no one should undertake the treatment, and the sooner the patient is sent to an asylum the better; but they are not always inevitable, even when they seem so at first, and many insane patients can quite well be treated at home. In such cases, these short notes may serve to indicate the evils to be chiefly avoided.

## REPORTS

OF

### MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS OF GREAT BRITAIN.

#### MIDDLESEX HOSPITAL.

CASE OF INTRACRANIAL OSTEOPHYTES WITH HYDROCEPHALUS:  
DEATH: CLINICAL REMARKS.

(Under the care of Dr. HENRY THOMPSON.)

RUTH CLEAVER, a servant, about twenty-three years of age, was admitted on January 14th, 1871. For some years she had been liable to severe throbbing headaches, and to a discharge from the right ear. She had also suffered a good deal lately from mental worry and distress. On June 18th, she was seized with an attack of vomiting, which lasted twenty-four hours, and then ceased on the administration of a dose of calomel. From that date the headache became more continuous and more severe.

On admission, the pulse was 68; respirations 20; temperature 98.2 deg. The patient was dull and stupid, complaining of acute throbbing pain, chiefly at the top of the head, but stretching down the back of the neck. There was great intolerance of light; the pupils were dilated, sluggish, and unequal; the right was the larger. The breath was fetid; the gums spongy and red. The tongue was coated with a thick creamy fur, and protruded slightly to the right side.

January 15th, 10 A.M. Pulse 58; respirations 20; temperature 98.8 deg. The extremities were cold. There was no action of the bowels or of the bladder. Urine was withdrawn by catheter; it was of specific gravity 1030, contained no albumen, and no sugar.—1.30 P.M. *Tache cérébrale* was readily produced and well developed. A roseolous blush appeared this morning in irregular patches over the neck and front of the chest, and, though fully pronounced at the time of the visit, disappeared entirely before the visit was over.—3.30 P.M. She was quite incoherent and comatose. Pulse 160, irregular in force and rhythm, short and sharp. The face was deeply flushed; the pupils were dilated, equal, unaffected by light.—4 P.M. The face and lips were intensely blue; the breathing slow and stertorous. Frothy fluid escaped from the mouth and nose. The pulse was too small and rapid to be counted. She died at 4.15 P.M.

*Necropsy*, twenty-four hours after death.—On removing the calvaria, the dura mater was found to be deeply injected; the convolutions were flattened, and the hemispheres gave the feeling of fluctuation to the touch. On removing the brain, a large quantity of perfectly clear fluid issued from the third ventricle. This, together with that withdrawn from the lateral ventricles, amounted to seven ounces. On slicing away the hemispheres, the white substance was found to be greatly softened, and the ventricles themselves enormously dilated. A portion of the softened material, submitted to the microscope, showed no appearance of granule-cells. There was no trace of tubercle to be found anywhere; nor was there any plugging discovered either in the

veins of the neck, the *venæ Galeni*, or the cerebral sinuses. Imbedded in the dura mater, and seemingly developed from it, were eight or ten thin plates of bone, not adherent to the calvaria. At the base of the skull, especially on the right side, there were several similar deposits, which adhered firmly to the temporal and occipital bones; and at these points the dura mater appeared to be wanting. With the above exceptions, the cranial bones were healthy. There was, however, a small vein plugged within the substance of the right petrous bone. In the thorax, the heart was small, its muscular substance firm; the aorta was atheromatous in patches; the aortic valves were thickened, with minute vegetations engrafted upon the thickened portion. The pericardium contained about an ounce of clear straw-coloured fluid. Both lungs were greatly congested, and attached to the chest-walls at various points by a few old fibrous adhesions; but they contained no tubercle. Several of the bronchial glands were reduced to cretified masses. No tubercle was discovered in the abdominal cavity or in its contents.

*Remarks by Dr. Thompson.*—At first sight, on a hasty glance at the history and symptoms of the above case, carries of the petrous bone, with its ordinary accompaniments and consequences, would almost inevitably have been the diagnosis which would have taken precedence of all others in the mind of the observer. Possibly, if this glance had been yet more superficial, and limited to existing symptoms alone, he might have entertained the idea of tubercular meningitis. Nothing of either kind was disclosed in the *post mortem* examination. There was no abscess of the brain; no unequivocal inflammation of its membranes; no pyæmia; no disorganisation of bone-substance; no thrombosis of sinus or vein, if we except the plugging of an insignificant venule within the right petrous bone—an event in itself of no material bearing on the pathology of the hydrocephalus. Again, there was no tubercle anywhere, nor anything akin to tubercle in the remotest degree, unless we so designate the cretified masses found in the bronchial glands. The key to the diagnosis was the long duration of the headache, which had lasted for some years before admission—a circumstance wholly incompatible with either of the above mentioned hypotheses, and pointing to the probability of some more or less massive or solid intracranial growth, although he would have been a bold man who should have diagnosed the particular growth discovered—the osteophytes developed originally from the dura mater; for such would appear to have been the origin of all the growths described, whether they were imbedded in the dura mater or adherent to the bones. In the absence of every other assignable cause, we can only conclude that these osteophytes played the part of tubercle in producing hydrocephalus. The peculiar membrane, the seat of their development, was indeed different; but the result was similar. The pathological changes proper to inflammation were less conspicuous; but the morbid process itself in all essential respects bore a strong analogy to that which is ordinarily set up by the presence of tubercle in the meninges. The so-called cerebral streak and the roseolous rash are worthy of a passing notice. Clearly they were the same phenomena under different aspects, and due to the same fine susceptibilities in the cutaneous circulation; the one presenting accidentally or spontaneously the same vascular engorgement which the other can be made to exhibit artificially.

#### CHILDREN'S HOSPITAL, BIRMINGHAM.

CHRONIC RHEUMATIC ARTHRITIS.

(Under the care of Dr. JOHNSTON.)

H. C., female, aged 7, was admitted an in-patient of the hospital on June 15th, with general rheumatic pains in all her joints, no one joint in particular being affected. There was no cardiac mischief. The left side of the face was flattened, the axis of the lower jaw on that side being directed towards the opposite side. The condyle could not be felt. There was no depression in front of the meatus auditorius. The molar teeth were decayed. She had some slight power of movement of the jaw, but could not speak at all distinctly. The left forearm was pronated and flexed. The elbow-joint was swollen, particularly on the radial side. The head of the radius could be felt much enlarged. On supinating and flexing the arm (which caused great pain), a crackling could be heard and felt in the joint. The mother said that, when three weeks old, the child came to the hospital with rheumatic fever, after which she was "paralysed"; but, after being under treatment for twelve months, she could use all her limbs well except the left arm, which was weak. About this time she noticed that the jaw-bone was "growing out of its place". There was then no swelling of the elbow-joint. When two years old, the child was run over, the wheel passing over the left elbow. A short time after this, the mother noticed that the joint was enlarging; and it has gradually increased till of its present size. The child suffers no pain except in changeable weather, when she has the rheumatic pains.

THE Subscriptions to the Association for the year 1871 became due in advance on January 1st. All which are not already paid, should be forwarded to the General Secretary, Mr. T. Watkin Williams, 13, New Hall Street, Birmingham; or to the Secretaries of Branches.

## BRITISH MEDICAL JOURNAL.

SATURDAY, AUGUST 5TH, 1871.

### THE ANNUAL MEETING.

THE list of papers to be read at the meeting next week, and the programme of the proceedings, promise a gathering of very great interest, and one which will, we hope, be largely attended. The Annual Addresses will be delivered by men remarkable for their philosophical innovations in theory as well as in practice, and in no way accustomed *stare super antiquas vias*. The papers to be read in the Sections will bear upon many subjects of large importance. Cholera will find its place in the Section of Medicine; and some of those best qualified to discuss its epidemiology, pathology, and treatment, will be present. In Public Medicine, we are promised discussions of the largest interest. The whole question of sanitary reorganisation will be raised by the report of the State Medicine Committee. Dr. Maunsell comes from Dublin to describe the Irish Poor-law Medical System, which is precisely on the order of the day as a subject of proximate legislation. Mr. Benson Baker will speak with authority of the defects of the English system, and their remedies. Mr. Hope will come from Edinburgh, at great personal inconvenience, to raise the question of Sewage Irrigation. There is much important business to discuss, of which it will require all the moderation, good sense, and mutual forbearance of members, to dispose satisfactorily.

The Local Committee, and the Local Secretary, Dr. Littleton, have spared no pains to make this meeting in every sense successful. The great beauty of the scenery of Plymouth and its neighbourhood will afford the opportunity of closing the meeting by holiday excursions of the most agreeable kind. We shall hope to be able to record next week that the efforts of all concerned to make this in every way a brilliant and numerous meeting have been altogether successful.

### MR. SIMON'S REPORT.

THE Thirteenth Annual Report of the Medical Officer of the Privy Council, although brief, contains much that is of considerable professional interest. Discussing the special diseases of the year 1870, he briefly notes the spread of relapsing fever at Liverpool, Leeds, and Merthyr Tydfil; the extraordinarily fatal prevalence of scarlatina in various parts of England; and the severity of the existing epidemic of small-pox. In respect to vaccination, £5,685 : 8 was awarded in gratuities to public vaccinators; one of the vaccinators of the Leeds Union receiving as much as £83 : 17 in gratuity; and the vaccinators of Salford Union together, £182 : 12. As many as 227,036 charges of lymph have been distributed by the central department.

The accelerated publication of the Registrar-General's quarterly reports has given facilities for the prosecution of earlier and more numerous sanitary inquiries. These disclosed local neglect generally of the grossest kind. The staff of the department being insufficient for the purpose, an appeal has been made to Parliament (and we believe successfully) to furnish larger funds for a more numerous staff.

Mr. Simon reviews the question of medical legislation pithily. He admits that the present construction of the General Medical Council, under the Act of 1858, "represents a kind of compromise between the profession and the public, arrived at with difficulty after long and renewed discussion, which, while it lasted, effectually prevented all legislation to amend the license system of the medical profession; and if that compromise were put forward for reconsideration, probably a new settle-

ment would be scarcely less difficult than the old;" but he is of opinion that "the two objects at which the Lord President's Bill of 1870 actually aimed were universally admitted to be of great and urgent importance to the public; and experience suggested that the attainment of those objects might be quite indefinitely delayed if, in endeavours to compass them by legislation, the constitution of the General Medical Council must also be treated as an open question."

On the pharmacy question, he drily observes that he believes it to have been by an accidental oversight in legislation that, while all other powers to be exercised for public purposes by the Society under the Act were vested in the Council of the Society, the language of the first section vested in the Commonalty, and not in the Council, the very important power which that section confers, and to which his present observations relate. It is, perhaps, not surprising that a large body of tradesmen should be slow to take the initiative in imposing even the most reasonable penal restrictions on themselves; but he submits, as a fact deserving the consideration of Parliament, that this non-fulfilment of the Society's duty, to make rules against dangerous slovenliness in the keeping, dispensing, and selling of poisons, is a breach of the implied contract under which the Legislature in 1868 gave powers and privileges to the Society.

Dr. Burdon Sanderson's highly interesting studies on contagion will receive from us a more detailed notice. Without altogether concurring in his reasoning, we accept his facts as a valuable contribution to science.

### ONE PORTAL FOR THE PROFESSION IN ENGLAND.

IN view of the legal difficulties which have been stated by the Society of Apothecaries to prevent that Society taking part in the formation of an Examining Board in this division of the United Kingdom, the following scheme has been approved by the governing bodies of the Royal Colleges of Physicians and Surgeons of England.

I. That a Board of Examiners be appointed in this division of the United Kingdom by the co-operation of the Royal College of Physicians of London, the Royal College of Surgeons of England, and of such other of the medical authorities in England, mentioned in Schedule (A) to the Medical Act, as may take part in its formation, it being understood that, liberty being left to such co-operating medical authorities to confer, as they think proper, their honorary distinctions and degrees, each of them will abstain from the exercise of its independent privilege of giving admission to the *Medical Register*.

II. That the Board be constituted of examiners, or of examiners and assessors appointed by the several co-operating medical authorities.

III. That the examiners be appointed on the following subjects: Anatomy and physiology; chemistry; materia medica, medical botany, and pharmacy; forensic medicine; medicine; surgery; midwifery; or on such subjects as may be hereafter required.

IV. That no examiner hold office for more than five successive years, and that no examiner who has continued in office for that period be eligible for re-election until after the expiration of one year.

V. That the examiners be appointed by the several co-operating medical authorities, on the nomination of a Committee, called herein "The Committee of Reference", but no member of the Committee of Reference shall be eligible for nomination as an examiner.

VI. That a Committee of Reference, to consist of an equal number of representatives of medicine and of surgery, be appointed as follows: One representative of medicine and one representative of surgery to be appointed by each of the Universities in England; four representatives of medicine to be appointed by the Royal College of Physicians of London; four representatives of surgery to be appointed by the Royal College of Surgeons of England.

VII. That one-fourth of the Committee of Reference go out of office annually, and that, after the first four years, no retiring member be re-eligible until after the expiration of one year.

VIII. That the duties of the Committee of Reference be generally as follows. I. To determine the number of examiners to be assigned to

each subject of examination; 2. To nominate the examiners for appointment by the several co-operating medical authorities; 3. To arrange and superintend all matters relating to the examinations, in accordance with regulations approved by the co-operating medical authorities; 4. To consider such questions in relation to the examinations as they may think fit, or such as shall be referred to them by any of the co-operating medical authorities, and to report their proceedings to all the said authorities.

IX. That there be two or more examinations on professional subjects, and that the fees of candidates be not less than thirty guineas, to be paid in two or more payments.

X. That every matriculated student of an English University who shall have completed the required curriculum of professional study, and shall have passed such an examination or examinations at his University as shall comprise the subjects of the primary examination or examinations conducted by the Board, be eligible for admission to the final examination; and that every candidate so admissible to examination be required to pay a fee of five guineas; but he shall not be thereby entitled to the Licence of the Royal College of Physicians of London, nor to the Diploma of Member of the Royal College of Surgeons of England, without the payment of an additional fee of not less than twenty-five guineas.

XI. That every candidate who shall have passed the final examination conducted by the Board shall, subject to the bye-laws of each licensing body, be entitled to receive the Licence of the Royal College of Physicians of London and the Diploma of Member of the Royal College of Surgeons of England.

We are happy to be able to state that the University of London gives its entire approval and co-operation to this scheme, suggesting only very slight alterations for the security of candidates proceeding from the Universities, to which the Corporations have already acceded in principle. These alterations are in Clause IV, to the effect that the examiners shall be subject to annual re-election; and in Clause XI, substituting the "curriculum required by their own University" for "the required curriculum of professional study". Subject to these amendments, which will obviously be accepted, the University of London consents to make a regulation that every candidate for the M.B. degree shall be required to pass the final examination of the Conjoint Board. The other Universities will, we believe, signify without delay their acceptance of the scheme, and will make the like concession.

It is difficult to exaggerate the importance of this step. The liberality of the Universities deserves the warmest praise: they have made important and distinct concessions, of great value to the public and the profession, although of none to themselves. The Corporations, too, have shown especially in the later steps of the negotiation an intelligent and liberal appreciation of the general good, which claims the warmest recognition. They have at every step met with ignorant abuse from one clique of writers, who put themselves forth as representing liberal opinions, but who have throughout shown a childish ignorance of the question at issue, and an utter incapacity to grasp its bearings. It remains for us, who have steadily adhered to the advocacy of the great principles which the British Medical Association has at heart, and of which one—the one portal—triumphs to-day, to express the earnest hope that the other divisions of the kingdom will follow this example, and that Ireland and Scotland will not long be left without unified Boards of Examination and one *minimum* test for all who enter the profession. It is a great step in medical reform, and augurs, we trust, the speedy triumph of the other principles of reform which our Association has, with the almost unanimous consent of the profession, declared essential parts of its programme—direct representation on the General Medical Council, and an efficient penal clause.

#### MEDICAL RELIEF, SCOTLAND.

THE Select Committee of the House of Commons on Poor Law (Scotland) have reported that the present condition of medical relief is

not generally satisfactory. The parochial boards are not obliged to appoint medical officers; and, when they are appointed, their tenure of office is uncertain, and their emoluments are not always such as to secure competent men. In England and in Ireland, the public Exchequer contributes one-half the actual amount expended in salaries to medical officers, and in medicines; whereas in Scotland a fixed sum of only £10,000 is granted from the public funds, which does not meet one-third of the very limited expenditure which occurs under this head in Scotland. The Committee agree with the suggestion that Scotland should be put upon as favourable a footing as England and Ireland in respect of grants from the public Exchequer on this account; that the local boards should be required to appoint medical officers, with a suitable salary, which should be exclusive of the cost of medicines; and that the dismissal of medical officers should be subject to the approval of the Board of Supervision. They recommend that every parochial board be required to appoint a medical officer at a suitable salary, exclusive of the cost of medicines; regard being had to the population and extent of the parish and the number of paupers. Medical officers not to be removed from office, except with the approval of the Board of Supervision. The Parliamentary grant in aid of medical relief to be placed on the same footing as it is in England and Ireland. Every parochial board be required to have, and furnish with requisite medicines, a dispensary at or in the vicinity of the residence of their medical officer; and to publish in their annual accounts a statement of medicines so supplied. As to pauper lunatics, they say that the evidence regarding the treatment and condition of pauper lunatics is, on the whole, satisfactory. The expense of maintaining pauper lunatics in asylums is a heavy and increasing charge; and it is suggested that, with a proper system of supervision, many more harmless lunatics might be advantageously either boarded out or removed to the lunatic wards of poorhouses, where their cost is much less than in asylums.

---

DR. CAYLEY has been appointed Physician to the London Fever Hospital.

THE *Northampton Herald* of July 29th records an heroic rescue of a lad from drowning by Dr. John M. Bryan, junior.

THE Working Men's Fund for the extension of the Queen's Hospital, Birmingham, has reached £5,465, of which £3,472 has been subscribed by artisans. It is proposed to close the fund in February next, at the end of the third year.

---

Dr. ALFRED MEADOWS has been elected Lecturer on Midwifery and the Diseases of Women and Children to St. Mary's Hospital Medical School, having recently also been appointed Physician-Accoucheur to the Hospital. Mr. Stocker, M.B.Lond., has been appointed Medical Tutor in the School.

---

By way of grateful return to a medical man of Cologne who took good care of him during his illness, a French officer, on his return to France from captivity, has, according to the *Kölnische Zeitung*, sent his photograph to the doctor, with a written certificate of his good treatment, and a request that his companions in arms should, in the "campaign of revenge", when they reached Cologne, treat the doctor with every consideration.

---

THE following is the list of Members elected as Fellows of the Royal College of Physicians. It was accidentally omitted last week:—Thomas Bishop, M.D., Paris; Arthur Leared, M.D., London; Gilbert William Child, M.D., Oxford; John Hitchman, M.D., Mickleover, near Derby; Augustus Drake, M.B., Exeter; Edward Copeman, M.D., Norwich; Willoughby Francis Wade, M.B., Birmingham; Philip Frank, M.D., London; Thomas Stevenson, M.D., Guy's Hospital; Charles Theodore Williams, M.D., Oxon., London; William Tilbury Fox, M.D., London; Edward John Waring, M.D., London; Philip John Hensley, M.D., London.

DR. JOHN MURRAY has been appointed Assistant-Physician to the Hospital for Sick Children, Great Ormond Street.

THE Swiss Federal Council have instructed their Consul-General in London to contradict a statement made by a London paper, which warned tourists from travelling in Switzerland on account of prevalence of small-pox. The disease, it is officially stated, showed itself in a few places in the spring, but has almost totally disappeared, the localities visited by strangers being entirely free.

#### BRITISH PHARMACEUTICAL CONFERENCE.

THE British Pharmaceutical Conference commenced its meetings on Tuesday in the Craigie Hall, St. Andrew's Square, Edinburgh. The President for the year is Mr. W. W. Stoddart, F.C.S., Bristol. There were about a hundred members present. A *conversazione* was given in the evening by the Chairman and Local Committee in Edinburgh, in the Museum of Science and Art.

#### THE CHOLERA.

No cases of cholera have as yet been recorded in this country this year, and thus there is little to be added to Mr. Forster's statement in the House of Commons. The amount of diarrhoea and choleraic diarrhoea registered in this country thus far is, moreover, below the average of previous years. This, however, is of course connected with the unusually low temperature of the season thus far. A few weeks of continued heat may tell a different tale. There is no doubt that the epidemic constitution which favours cholera, and the particular contagion which conveys it, are steadily advancing upon us, following their usual march. Mr. J. N. Radcliffe, Inspector of the Privy Council, is now visiting the eastern ports, and is at present at Sunderland, charged with a special mission of informing the local authorities of their special powers and duties under the late order in Council, and conferring with them as to the proper precautions to be taken. They have, we believe, shown every disposition to concur in all possible precautions.

#### THE BERKSHIRE CAMPAIGN.

WE have reason to fear that the officers of the Medical Department of the Army do not fully appreciate that unaccustomed and remarkable subordination of military projects to presumed sanitary considerations which has put an end to an important series of manoeuvres, for fear of injuring the men's health by exposure to the "equinoctial gales" which prevail in September on the plains of Berkshire. It is less, however, with the view of reassuring Lord Northbrooke, than of re-establishing the facts on their proper basis, that we state that his fears are not shared by the medical officers of the army, and that they have never entertained any apprehension but that the resources of art and rules of hygiene might be successfully applied to enable the British soldier to encounter an ordeal even more severe than that of a mock campaign among the autumn stubbles in the royal county. The health-returns of the troops in the campaigns of China, Australia, and Abyssinia, and the well devised and successful resistance of the Guards to the depths of a Canadian winter, taught other lessons than these; and it is a pity that they should be misread. Nor is it altogether fair that the officers of this department should be made the scapegoats of what would seem to be the shortcomings of others.

#### PHYSICIANS IN THE UNITED STATES.

WE take the following facts from the *Philadelphia Medical Times*:—"The total number of physicians who paid taxes to the Government for the year ending April 30, 1871, was 49,798. Of these there were—regular, 39,070; homœopathic, 2,961; hydropathic, 133; eclectic, 2,860; miscellaneous or not classified, 4,770. These figures show that the number engaged in the profession has been over-estimated. The usual guess at the number of homœopaths has been 10,000. It is believed that the Government list is very full and accurate." It is said that the Internal Revenue Department has prepared a list giving the name and post-office address of every one of the 49,798 physicians.

#### PREPARING FOR THE CHOLERA.

THE condition of Stanwix in the Carlisle Union does not appear yet to have engaged the attention of the Privy Council; but it seems to be as well disposed as any district could be to invite the approaches and diffuse the ravages of Asiatic cholera. Its water-supply, we observe from a special report to the guardians, is not only defective, but largely contaminated by sewage; and in many of the "ash-pits" are large accumulations of decomposing sewage, so placed as to be in actual contact with the walls of adjacent houses and above the level of the floors. These accumulations are described in the report of the Sanitary Committee as being repulsive to sight and offensive to smell, outrages on decency, and dangerous to health. From various local causes, it seems little likely that any effectual remedy will be applied—at any rate for an indefinite time. The prospect before the inhabitants of Stanwix and those into whose homes they are well-fitted to import zymotic disease, is not altogether cheerful.

#### THE EDINBURGH UNIVERSITY CLUB.

A GENERAL MEETING of the members of this club was held at St. James's Hall Restaurant, 69, Regent Street, W., on Tuesday, August 1st, 1871; Dr. E. H. Sieveking, V.P., in the chair. Dr. George T. Mitchell and Mr. Frederick Churchill, were unanimously elected members of the club. Dr. Andrew Clark, President of the Medical Society of London, was nominated as a member of the club. Dr. Sieveking then presented a very handsome mull and box of snuff to the club, and he hoped that the club might soon possess a "loving cup" of its own. It was proposed by Mr. Batten, and seconded by Dr. Halley, Honorary Treasurer: "That the cordial thanks of the meeting be given to Dr. Sieveking for his handsome present of a mull." The dinner then followed; Dr. Lyon Playfair, M.P., C.B., in the chair. Twenty members and ten guests were present. Congratulations were conveyed by telegraph to the new graduates of the University of Edinburgh (August 1st being capping-day); and their reply of thanks was received and read by the Chairman during the dinner amidst much enthusiasm. A subcommittee was appointed to take steps to purchase a "loving-cup" for the club; the subscription-list was opened, and twenty guineas were at once announced. Each member will receive in the course of a few days a letter, asking him to join the list of subscribers. The cup will be presented to the members at the next dinner. Dr. Playfair made some interesting remarks on the work done in Parliament during the Session; and stated that the medical element, at any rate, had not been wanting in zeal; and that their labours would be found in the Acts relating to Baby-farming and Local Government. Some excellent songs were sung; and the meeting passed off very successfully.

#### SERO SED SAPIENTER.

PROMOTION in the naval medical line has lately been very slow, but it is stated that, probably, there will be several assistant-surgeons promoted at an early date.

#### THE INTERNATIONAL AID SOCIETY.

THE International Aid Society held this week its annual meeting. It has still a reserve of £73,000, and will, we are glad to learn, seek for a Royal Charter. The Society has issued an extremely interesting report of its operations, accompanied by maps, and a special report by Dr. Sutherland, of the War Office, on the correspondence from the agents of the Society. A further volume records the criticisms of the working-staff of the Society on the operation of the treaty of Geneva, and the results of the Society's labours during the Franco-Prussian war. We greatly regret that an overwhelming pressure of matter prevents us now from entering into these subjects in detail, and comparing the conclusions with those derivable from other personal experience at our disposal. We shall not, however, delay to congratulate the Society, and especially Colonel Loyd Lindsay and Captain Burgess, on whom the chief labour and responsibility of central organisation fell during twelve months, on having worked through what was very like early failure to

final success of an admirable character. These reports, coming chiefly from those actually in the service of the Society, and for many reasons far more likely to describe its and their achievements than their shortcomings, are nevertheless marked by a commendable candour. Some critics, whose observations could hardly have failed to jar somewhat upon the sweet music of the laudatory chorus of the staff, have considerably refrained altogether from replying. Thus these volumes stand as fair records of a noble achievement, of which Englishmen will never think without thankfulness that they were permitted to take part in a work of mercy so unstained, pure, and far-reaching.

#### ADULTERATION OF FOOD, DRINK, AND DRUGS.

LORD EUSTACE CECIL has given notice that, failing the action of the Government to bring in a measure to amend the law relating to the adulteration of food, drink, and drugs, or to introduce clauses for that purpose in any sanitary Act which they may propose, he will early next Session again propose a resolution upon the subject for the consideration of the House.

#### HOSPITAL ACCOUNTS.

A GOVERNOR of St. Mary's Hospital writes to us as follows, touching our note of last week on Hospital Statistics. "It is refreshing to find any one advocating the desirability of rendering accounts in an uniform and intelligible shape; but Mr. Kemble is, I fancy, rather out when he starts the idea as a new one. Mr. J. G. Wilkinson urged it in his very able pamphlet, of which you have taken prominent notice; and the Social Science Association not only took the matter up, but printed and circulated a form of balance-sheet whereby the accounts of hospitals might be rendered in an uniform shape, with classification sufficient for all purposes of comparison. The public, however, do not appear to attach any importance to this subject; and while secretaries are, as a rule, hostile, and governing bodies indifferent, I fear that things will have to go on in their present very unsatisfactory state. Mr. Kemble's suggestion for showing the cost of the medicine ordered for each class of patients, and the different diets separately, rather amused me. Even if it were practicable, I cannot understand what advantage would be gained by such minute details."

#### THE CITY WATER-SUPPLY.

At a recent meeting of the Common Council of London, Mr. Rudkin called attention, amid marked expressions of approval, to the present state of the water-supply in the City. He said he knew instances where persons were suffering from the effects of the bad quality of the water, and it had occurred to him that it would be desirable, in view of existing facts and apprehensions, to induce the water companies to have recourse for a time to water-posts, as in winter, at stated places, so that the poor people living in confined courts and alleys might get a supply of water fresh from the mains, instead of from stagnant cisterns. Mr. De Jersey, Chairman of the Commissioners of Sewers, undertook to use his influence with the water companies to do everything in their power that might be thought desirable under the circumstances. Mr. Dremer Rogers was glad to say, with reference to the Metropolitan Water Bill (No. 2) now before Parliament, that the Corporation had obtained a concession, under which the entire supervision of the water-supply would be in the hands of the Corporation itself. We commend this example to the notice of other Corporations.

#### THE ALBERT IDIOT ASYLUM.

THE Emperor of Brazil has extended his visit to the Royal Albert Asylum for Idiots and Imbeciles at Lancaster. The interest evinced by the Emperor in every detail relating to the work of idiot-training was alike creditable to his intelligence and his humanity. This asylum is now in full operation, under the medical superintendence of Dr. G. E. Shuttleworth, and contains sixty patients. Free cases are received only from the seven northern counties; full payment cases from all parts. We observe that the Lunacy Commissioners, in their annual report just issued, speak in the highest terms of the asylum, and pay a

just tribute to the energy of its benevolent founder, Dr. De Vitre. They express a hope that similar energy may evoke like liberality, and lead to the foundation of sister institutions in other divisions of the kingdom.

#### BABY-FARMING.

AT the Manchester assizes on Saturday, before Mr. Baron Martin, Frances Rogers, a baby-farmer, was tried on the charge of doing grievous bodily harm with intent to kill, and sentenced to twenty years' penal servitude. The case gone into was that of the child of a woman named Agnes Murray, which the prisoner had undertaken to take charge of for £8. There were other indictments relating to the cases of Elaine Bennett, James Gallagher, and a child named Robinson. In all these cases laudanum had been administered systematically to allay hunger.

#### THE CONTAGIOUS DISEASES ACTS.

In the House of Commons this week, in answer to questions from Sir J. Elphinstone and Mr. Baines touching the literature of the Contagious Diseases Acts controversy, Mr. Bruce said that if it were conducted with discretion no law could interfere with it, but if it degenerated into a tone of grossness it would be for the Courts to say whether it came within Lord Campbell's Act.

#### CHOLERA IN PERSIA.

NOTWITHSTANDING conflicting statements and the very energetic denial by the Persian minister, it is confirmed that famine, cholera, and a pestilential disease described as plague, have been prevalent recently in Persia, although to an extent much less than might be gathered from current reports.

#### UNIVERSITY COLLEGE, LONDON.

At an extraordinary general meeting of the members of the College on Saturday, July 29th, the Right Hon. Lord Belper, LL.D., F.R.S., was unanimously elected President of the College, in the place of the late Mr. George Grote. At a session of the Council, on the same day, the following appointments were made: Dr. Charlton Bastian, F.R.S., to be Physician to University College Hospital; Mr. Berkeley Hill, Mr. Christopher Heath, and Mr. Marcus Beck, to be Teachers of Practical Surgery. The Sharpey Scholarship, recently established for the promotion of the study of Biological Science in the College, was conferred upon Mr. E. A. Schäfer.

#### THE MIDDLESEX HOSPITAL.

THE death of Mr. Francis Broderip has disclosed the name of a munificent benefactor to the above institution. Early in 1866 the then Chairman of the Weekly Board, Mr. Michael Smith, reported an anonymous donation of £20,000, 4 per cent. Brazilian Bonds, to the funds of the hospital; and now that the death of the donor has released Mr. M. Smith from his promise of secrecy, he has informed the Weekly Board that Mr. Francis Broderip was this benefactor, and that at the same time he promised an annual subscription during his lifetime of £100 towards the Samaritan Fund.

#### ACCIDENTAL POISONING.

A GENTLEMAN named Wall, aged 33, living at Salcombe Regis, near Sidmouth, who was in the habit of taking morphia, sent the other day a prescription to a druggist named Webber, for a mixture containing a small quantity of that narcotic. Having received the medicine he took a dose of it and went to bed. Soon afterwards his wife noticed that he was breathing unnaturally, and sent for a medical man. Meanwhile, the druggist discovered that he had made a mistake, having put an excess of muriate of morphia into the mixture, and immediately despatched a messenger to obtain possession of the bottle, but too late, half of the quantity taken being enough to kill an habitual morphia taker. Everything was done by the medical men who attended Mr.

Wall, but he died a few hours afterwards. "Death by misadventure" was the verdict at the inquest, and the druggist was admonished "to be more careful for the future".

A SEPARATION of the Siamese twins now appears imminent. One is said to be at the point of death, at their home in North Carolina. The other is in good health. In anticipation of death, arrangements have been made for the immediate separation of the living from the dead brother.

THE list of pensions granted during the year ending the 20th of June, 1871, and charged upon the Civil List, includes only one medical name: Gavin Milroy, Doctor of Medicine, in consideration of his medical services under Government, and especially in the Crimea, and of the injury which he thereby professionally sustained, £100.

AN American lady, Miss Patnam, who has been a student of medicine in Paris for some years, has just graduated in medicine with highest honours at the University in that city.

MR. J. K. KENVON, Medical Officer and Public Vaccinator of No. 3 District of the Highworth and Swindon Union, has received a gratuity of five guineas from the Lords of the Privy Council, for successful vaccination in his district.

## SCOTLAND.

### THE SYME TESTIMONIAL FUND.

EXACTLY two years ago, a preliminary meeting was held in London for the purpose of taking steps to inaugurate a testimonial to Mr. Syme, on the occasion of his relinquishing the Chair of Clinical Surgery in the University of Edinburgh, the result of which was a large and influential public meeting in St. James's Hall in the ensuing November. At this meeting, it was resolved that a suitable memorial of the great surgeon should be raised, and that it should take the form of a fellowship for the promotion of surgery in the University of Edinburgh, to be called "The Syme Surgical Fellowship"; and a marble bust, to be placed in the University Library, or in the Hall of the new Royal Infirmary. Dr. Murchison, who had taken the initiative in promoting the testimonial, was appointed Honorary Secretary. He has now issued his Report of the Syme Testimonial Fund, and it is exceedingly satisfactory. The total sum raised in Great Britain, America (which contributed handsomely), and the colonies, amounts to £2,295:10:11, which includes a liberal donation of £305 by Mr. Syme's son in memory of his distinguished father. This sum has enabled the Committee to present an admirable life-like marble bust of Mr. Syme, by Mr. Brodie of Edinburgh, to the University of Edinburgh, as well as to the Royal Infirmary. There remains, after deducting all expenses, the sum of £2,000 for the foundation of the fellowship; and, by an arrangement with the Association for the better Endowment of the University of Edinburgh, this sum has been augmented to £2,500. The first competition for the fellowship will take place some time during the year 1874. The chief feature of, and condition in holding, the fellowship, are, that it will be of the value of about £100, tenable for two years, or, under certain circumstances, a longer period; and that it will be awarded to the competitor, who must be a Bachelor of Medicine of the University of Edinburgh of not more than three years' standing, and who shall present the best thesis on a surgical subject, giving evidence of original research or practical talent. The conditions under which the fellowship is to be held are, we think, those which are likely to encourage original surgical talent, of which Mr. Syme was so brilliant an example. That the completion of the testimonial has been successful beyond expectation, must be gratifying to Mr. Syme's old friends and pupils, and especially so to Dr. Murchison, to whose exertions the success of the testimonial is largely due.

### UNIVERSITY OF EDINBURGH: GRADUATION CEREMONIAL.

THE "capping" of the medical graduates took place on Tuesday, before a large assemblage of ladies and gentlemen. The Lord Justice General, Chancellor of the University, occupied the Chair. The degree of LL.D. was conferred on the following, amongst other gentlemen, before the ceremony of graduation in medicine. Professor Thomas Andrews, F.R.S., of Belfast; Dr. W. B. Carpenter, F.R.S., of London; Dr. G. E. Paget, of Cambridge; Professor Allen Thomson, of Glasgow; and the Anatomist Professor Pierre Joseph Beneden, of Louvain. Professor Bennett delivered the graduation address.

### THE EDINBURGH UNIVERSITY: THE SENATUS AND THE LADY STUDENTS.

THE Senatus have arrived at the following decision on Miss Jex Blake's communication, in which she made application that opportunities should be afforded to the lady students to enable them to complete their medical education in Edinburgh: "That the Senatus intimate to Miss Jex Blake that, having taken the opinion of counsel with reference to the proposals contained in her memorial of date 26th June, 1871, they find themselves unable to comply with either of those proposals." It is stated that the Senatus was very equally divided, the resolution being carried by the casting vote of the chairman. The Senatus asked the opinion of counsel as to their adopting either of Miss Jex Blake's suggestions, and as to the rights of the lady medical students to examination and graduation. The opinion, we understand, amounted to this, that, whether matriculated by permission or not, women had no legal status in the University. The other motion brought forward was to the effect that the opinion and accompanying papers be sent to the University Court with a strong expression of the desire of the Senatus that the lady medical students should in some way be enabled to continue their studies. The subject will probably be brought up again in October.

### THE NORTH OF SCOTLAND MEDICAL ASSOCIATION.

THIS Association held its annual meeting in the Medical Hall, King Street, Aberdeen, on Saturday, July 29th. Dr. Davidson of Wartle presided. The President, before the commencement of the business of the meeting, passed a high eulogium on the late Dr. Keith, who had immediately preceded him in the presidential chair. A report, prepared by the Aberdeen Medico-Chirurgical Society, on the Existence of Small-pox and other Epidemics in the Locality, was presented by Dr. Beveridge. The report shewed that there was little occasion for anxiety as regards small-pox, its prevalence being very slight. Dr. Jamieson of Peterhead, Dr. Mackie of Inch, Dr. Gavin of Strichen, and others, having offered some remarks on the subject of small-pox and vaccination, the following motion was proposed by Dr. Mackie, Inch, seconded by Dr. Jamieson, Peterhead, and, after some discussion, ultimately carried: "That this Association, considering it is very desirable that a general understanding be come to with regard to professional conduct in the intercourse of members, resolves to appoint a Committee to prepare a code of rules to be submitted to the next meeting." The President and Secretary of each of the district societies were appointed a Committee on the subject. Professor Inglis read a paper on a case of Cesarean Section. The Treasurer's accounts were submitted. Professor Ogston was appointed President for the ensuing year. The members then paid a visit to the Infirmary, and afterwards dined together in the Great Northern Hotel.

## IRELAND.

### APOTHECARIES' HALL, IRELAND.

THE Governor and Court of Examiners of the above institution gave a dinner at the Exhibition Palace, Dublin, on Thursday, July 27, to which the following received invitations: Dr. Banks, President of the College of Physicians; Mr. Wharton, President of the Royal College of Surgeons; Sir D. J. Corrigan, Bart., M.P.; Dr. Stokes; Mr. Adams; Mr. Porter; Sir W. Wilde; Sir Wm. Carroll; Dr. Macnamara; Dr. M'Dowd;

Dr. Churchill; Dr. Ringland; Dr. Albert Walsh; Dr. G. Johnstone; Dr. Hargrave; Dr. Denham; Dr. Kidd; Dr. Cruise; Rev. Dr. Haughton; Dr. Hudson. After the usual loyal toasts, "The Health of the President of the King and Queen's College of Physicians" was proposed. In responding, Dr. Banks dwelt upon the benefit and mutual advantage of the representatives of the whole profession thus meeting together. Mr. Wharton, as President of the Royal College of Surgeons, returning thanks for his health, spoke of the desirability of a union of the several branches of the profession, and of the formation of an Irish conjoint board of examiners. The "Health of the Governor and Court of the Apothecaries' Hall" was proposed by Dr. Banks. The "Health of the Rev. Professor Haughton", in connection with Trinity College, was proposed by Dr. Harvey, and warmly responded to. Dr. Haughton, in returning thanks, mentioned the continuous efforts made by each of the medical educational bodies of Ireland in the cause of advancing the profession. He pointed out the great benefit that would accrue from unanimity, and asserted for Ireland the right to regulate the education of her youth in accordance with that respect for the Deity which had from the very earliest ages of Christianity marked the teaching of her schools.

## THE CHOLERA.

### THE CHOLERA AND THE GOVERNMENT.

On Friday night, in answer to Mr. Hardy, Mr. Forster made the following statement as to the dreaded outbreak of cholera.

"For the last two years cholera has been in Russia, and since last August in St. Petersburg. Since April of this year it has been in Wilna and other western places; recently, it has increased in St. Petersburg, but not nearly so much there as some months ago, and the disease is said to be diffused through the western provinces of Russia. We need not assume that this bodes any immediate danger to this country. We have no knowledge of any cases in Germany; but the Foreign Office is to make special inquiry on this point at Berlin. While thus there is no reason for immediate alarm, or for any particular action of central authority, there is ample reason that local authorities should exert themselves in the removal of nuisances, and should watch with extreme care over the sources of water-supply within their districts. Water-companies should be mindful that the greatest disasters produced by cholera in this country have been due to their distribution of sewage-tainted water, and every care should be used by them, in good time, to prevent the recurrence of any such mischief. Their customers, too, should watch them narrowly."

Notwithstanding this statement, however, it appears that, from information received on that evening, Mr. J. N. Radcliffe, one of the inspectors of the Privy Council, was despatched that night to Hull to investigate the facts connected with a reported outbreak of cholera in ships from the Baltic, and found, on his arrival there, that two ships had come into the port from Cronstadt, and that a fatal case of cholera had occurred in each—in one two days before, in the other two days after, sailing. In the latter, therefore, the death had happened when the ship was only five days from England. No other cases had occurred, and there had been no cholera in Hull itself. The facts, however, made it clear that danger was to be apprehended on the side of the Baltic, from which sea, from now until October, a constant stream of vessels will be entering Hull and other eastern ports. The course of the emigration from North Germany to America is by way of Hull and Liverpool; and it will be remembered that on a former occasion cholera broke out among these emigrants only when they had reached the latter port, and were about again to embark. In Hull itself the docks are absolutely within the town, so that ships are moored immediately against houses, and in this position they are sufficiently under the jurisdiction of the local authority. The Lords of the Privy Council, however, on hearing Mr. Radcliffe's report, determined still further to protect the town by an order, which was issued on Saturday, under which all ships arriving from the Baltic will be examined before they enter the port; and any necessary measures of isolation or disinfection will be strictly enforced. At the same time Mr. Radcliffe was again despatched to the north, with instructions to visit all the eastern ports in order to give necessary information and injunctions to local authorities with regard to the measures to be taken under the order, and also to proceed to Liverpool and Birkenhead to insure that due provisions are made for dealing with cholera if it appear among any emigrants who have been allowed to land at Hull and to

continue on their way. At present, although there is abundant necessity for precaution, nothing has occurred to justify grave alarm, and it may reasonably be hoped that the precautions taken will prove effectual. The order, published in the *Gazette* of Saturday, provides that ships coming from districts in which cholera prevails may be inspected by the nuisance authority of the district. On the arrival of such a ship the nuisance authority shall cause all persons on board to be examined by a doctor; and, while those free from the disease will be allowed to land, those infected shall be removed to a hospital or otherwise dealt with. If any death from cholera take place on board, the body shall be taken out to sea and there committed to the deep, and the clothing, bedding, etc., on board, with which the patient has come in contact, must be disinfected or destroyed.

### CHOLERA IN PERSIA.

As regards cholera in Persia, the Persian Minister here writes, there is no occasion to take any exceptional notice of it. "Every year at the period of excessive heat, the imprudent consumption of fruit gives rise to a certain number of cases, and this number has not been exceeded in any remarkable proportion." The alarming telegrams about the cholera, the writer believes to be "the wretched expedient of some agent of a commercial house, or of some one employed in connection with the telegraphs who has been detained at Teheran during the insupportable hot season while his colleagues or friends have gone to the neighbouring mountains in search of a cooler atmosphere, and who has endeavoured by publicity to inspire such fears to supply a motive for his departure from Teheran, or to secure for himself some exceptional privilege as a reward for having remained at his post under such painful circumstances."

### CHOLERA IN INDIA.

FROM Indian papers we learn that cholera has broken out at Berhampore, and we are very sorry to learn that one of the first victims of the disease was Dr. John White, the civil surgeon of the station. Dr. Ewart has been called to Berhampore. Happily, the type is not epidemic.

### CHOLERA IN RUSSIA.

THE *Moscow Gazette* publishes the following return respecting the spread of cholera in Russia. "On the 17th July, 100 persons were attacked with cholera in Wilna, and 40 died; on the 18th, 62 were attacked, and 30 died; on the 19th, the cases of illness rose to 281. At Riga, hospitals are already established for the exclusive use of cholera patients, and physicians are kept on duty day and night. The epidemic is approaching the Prussian frontier."

### CHOLERA IN BERLIN.

It is stated in the weekly health-return from Berlin that the reports as to the progress of the cholera are incomplete, but that it is certainly entering Riga on the Baltic, at the mouth of the Dwina. In Tambow, out of 30,000 inhabitants, 458 died from cholera in the week ending July 13th: this is in Central Russia, where the sanitary conditions are unfavourable. The English Registrar-General points out how important it is at the present time that the greatest energy should be used in securing prompt and efficient treatment in the earliest stages of diarrhoea, "for it cannot be too generally known that all cases of cholera commence with diarrhoea."

Reports from Berlin, under date August 2nd, say the cholera epidemic has crossed the Prussian frontier. The first case has occurred at Königsberg, where a Polish Jew was attacked by it and died. On the same day two other persons were reported ill, one of whom died. No further reports have arrived yet.

The reports from Russia are unsatisfactory. On the 25th July, 595 cholera patients were in the hospitals at Moscow, and the same day 102 fresh cases were reported. Up to that date there had been 3125 cases, of which 1428 proved fatal, in addition to those cases which may not have been reported to the authorities. At the same period there were 103 patients in Riga, and 55 new cases, with 48 deaths, on the same day.

THE foundation-stone of the Barnes Convalescent Home at Cheadle, in connection with the Royal Infirmary, Manchester, was laid on Saturday last by Hugh Birley, Esq., one of the members of Parliament for the city, in the presence of the Bishop of the Diocese and others.

TESTIMONIAL.—Mr. A. L. Peacock, surgeon, of Churchingford, Devon, has been presented with a handsome silver tea-service by a number of friends as a token of esteem, and of regret at his leaving the neighbourhood.

## ASSOCIATION INTELLIGENCE.

BRITISH MEDICAL ASSOCIATION:  
ANNUAL MEETING.

THE Thirty-ninth Annual Meeting of the British Medical Association will be held in Plymouth, on Tuesday, Wednesday, Thursday, and Friday, the 8th, 9th, 10th, and 11th of August next.

*President*—E. CHARLTON, M.D., D.C.L., Physician to the New-castle-upon-Tyne Infirmary.

*President-elect*—JOHN WHIPPLE, Esq., F.R.C.S., Consulting Surgeon to the South Devon and East Cornwall Hospital.

An *Address in Medicine* will be delivered by GEORGE JOHNSON, M.D., F.R.C.P., Professor of Medicine in King's College, London.

An *Address in Surgery* will be delivered by JOSEPH LISTER, Esq., F.R.S., Professor of Clinical Surgery in the University of Edinburgh.

The business of the meeting will be conducted under four Sections.

**SECTION A. MEDICINE.**—*President*, Dr. Barham, Truro. *Vice-Presidents*—Dr. Quain, F.R.S., London; Inspector-General Smart, M.D., C.B., R.N., Penge, Surrey. *Secretaries*—Dr. Clay, Windsor Villas, Plymouth; Dr. Wade, Temple Row, Birmingham.

**SECTION B. SURGERY.**—*President*—Joseph May, Esq., Stoke, Devonport. *Vice-Presidents*—P. C. De la Garde, Esq., Exeter; Deputy-Inspector-General Longmore, C.B., Netley. *Secretaries*—W. P. Swain, Esq., Ker Street, Devonport; C. Steele, Esq., Meridian Place, Clifton, Bristol.

**SECTION C. MIDWIFERY.**—*President*—Dr. Beatty, Dublin. *Vice-Presidents*—Dr. Swayne, Clifton, Bristol; Dr. Alfred Meadows, London. *Secretaries*—Dr. John Rolston, Stoke, Devonport; Dr. Phillips, 26, Finsbury Square, London, E.C.

**SECTION D. PUBLIC MEDICINE.**—*President*—Dr. A. P. Stewart, London. *Vice-Presidents*—P. W. Swain, Esq., Stoke, Devonport; Dr. Beddoe, Clifton, Bristol. *Secretaries*—Dr. Row, Ker Street, Devonport; David Davies, Esq., 2, Queen Square, Bristol.

## TUESDAY, August 8th.

The meetings this day will be held at the Royal Hotel, PLYMOUTH.

1 P.M.—MEETING OF COMMITTEE OF COUNCIL.

3 P.M.—MEETING OF GENERAL COUNCIL.

8 P.M.—FIRST GENERAL MEETING. *Business*: a. Reception of Congratulatory Address from Plymouth Corporation; b. President's Address; c. Vote of thanks to the President; d. Report of Council, and Discussion thereon; e. Election of General Secretary; f. Election of Auditors; g. Report of Medical Benevolent Fund; h. Presentation of Hastings Medal.

## WEDNESDAY, August 9th.

8.30 A.M.—PUBLIC BREAKFAST—Royal Hotel, DEVONPORT.

9.30 A.M.—MEETING OF NEW COUNCIL—Royal Hotel, DEVONPORT.

11 A.M.—SECOND GENERAL MEETING—Town Hall, DEVONPORT. *Business*: a. Reception of Congratulatory Address from Devonport Corporation; b. To appoint place of meeting for 1872, and President-elect; c. Address in Medicine by Dr. GEORGE JOHNSON.

1 P.M.—Adjourn.

2 P.M.—MEETINGS OF SECTIONS—Royal Hotel, PLYMOUTH.

9 P.M.—PRESIDENT'S SOIRÉE—Assembly Rooms, Royal Hotel, PLYMOUTH.

## THURSDAY, August 10th.

9.30 A.M.—MEETING OF COMMITTEE ON REGISTRATION OF DISEASE—Public Dispensary, Catherine Street, PLYMOUTH.

10 A.M.—THIRD GENERAL MEETING. *Business*: Reports of Committees—Royal Hotel, PLYMOUTH.

11 A.M.—ADDRESS IN SURGERY, by Professor LISTER, F.R.S.—Royal Hotel, PLYMOUTH.

2 P.M.—MEETINGS OF SECTIONS—Royal Hotel, PLYMOUTH.

6.30 P.M.—PUBLIC DINNER—St. George's Hall, STONEHOUSE. For Dinner Tickets, an early application (enclosing One Guinea) should be made to P. W. Swain, Esq., F.R.C.S., Stoke, Devonport. The services of the far-famed Band of the Royal Marines have been engaged for this occasion.

## FRIDAY, August 11th.

10 A.M.—MEETINGS OF SECTIONS—Royal Hotel, PLYMOUTH.

2 P.M.—CONCLUDING GENERAL MEETING—Royal Hotel, PLYMOUTH.

A RECEPTION ROOM will be opened at the Royal Eye Infirmary,

close by the Plymouth Railway Station. Members and others who require information with respect to the meeting are requested to make application in this room. Information as to Lodgings will be furnished there.

Members are requested to proceed to the Reception-Room immediately on their arrival, to enter their names and addresses, and to obtain the tickets necessary to secure admission to all the proceedings.

**HOTELS.**—The principal hotels are, at PLYMOUTH, the Royal Hotel, the Duke of Cornwall, the Globe, the Albion, Chubb's Hotel, Farley's Hotel, Harvey's Hotel; at DEVONPORT, the Royal Hotel, Thomas's Hotel, and the Crown Hotel.

The GUIDE-BOOKS FOR DEVON AND CORNWALL are: Murray's *Handbook of Devon and Cornwall*; Black's *Guide to Devon and Cornwall*; Blight's *Week at the Land's End*; Rev. — John's *Week at the Lizard*; and, for Plymouth and the neighbourhood, Brendon's and Luke's *Guide-books*—both by Lt. Jewitt, F.S.A.

\*\*\* GENTLEMEN INTENDING TO VISIT PLYMOUTH during the meeting are requested to send their names to Dr. Littleton, the Local Secretary, 1, Lansdowne Place, Plymouth.

**NOTICES OF MOTION.**—The following notices have been given.

The PRESIDENT OF THE COUNCIL: Rule 4. To insert "President-elect", and to omit "Secretary".—Rule 6. To expunge this rule, and to substitute the following: "Each retiring President of the Association and President of Council shall be appointed a Vice-President for life by a vote of the members at the Annual Meeting."—Rule 7. To add "the Vice-Presidents" after President-elect; to insert the word "and" between President of the Council and Treasurer, and to erase "and the Secretary".—Rule 8. In this and every rule where "District" is prefixed to Branch, to erase the word "District", and to erase the words "the Secretary of the Association".—Rule 9. To omit the words between "The President of the Council" and "shall be elected".—Rule 10. To omit the words between "The Treasurer" and "shall be elected".—Rule 11. To erase the words after "There shall be one paid Secretary" in first section, and to substitute "who shall reside in London, and devote his whole time to the business management of the Association and of the Journal office". To erase the words "otherwise" in seventh line and "an annual or special" in eighth line, and to insert "each Annual Meeting".—Rule 13. To erase the words "Secretary shall call", and to substitute "President of Council shall direct to be called".—Rule 14. Between "shall" and "be recommended", to insert "express his desire in writing, and shall be".—Rule 15. To add "Members may be admitted on and after July 1st in each year, and the subscription for such part of a year shall be half a guinea". To erase the words after "such member" in eighth line, and to substitute "as long as his subscriptions remain unpaid, provided due notice shall have been given of such withholding".—Rule 16. To erase the words after "from his" in fourth line, and to substitute "liabilities to the Association".—Rule 24. In tenth line, to insert "a copy of the laws" between "Association" and "and".

Dr. STEELE (Liverpool): Election of Committee of Council. Every associate, who is a member of the Council, and desirous of a seat on the Committee of Council, shall send to the General Secretary, not later than months prior to the Annual Meeting of the Association, a declaration signed by himself, and in the following terms: "I, A. B., of C., member of the British Medical Association, hereby declare that I am a candidate for a seat on the Committee of Council of the said Association. (Signed) ———." Together with a nomination-paper signed by six members of the Association, in the following terms: "We, the undersigned, members of the British Medical Association, certify that A. B., of C., is a fit and proper person to be a member of the Committee of Council of the said Association." The names of the eligible candidates, with the names of the six associates by whom they shall have been respectively nominated, shall be published in the BRITISH MEDICAL JOURNAL not later than months prior to the Annual Meeting of the Association.

Mr. NICHOLSON (Hull): To alter Law 16, line 2. For "three", insert "two".

Dr. WADE (Birmingham): In Law 8, Paragraph No. 3, of the duties of Council, to alter "ten" into "twenty-five"; and to omit the words "and one Secretary from each Branch".

**INVITATION TO TORQUAY.**—The members of the medical profession at Torquay request the pleasure of the company at luncheon, on Saturday, August 12th, at 3 o'clock, of any member of the British Medical Association residing beyond fifty miles from the place. Their object in this limitation as to distance is that of furnishing an opportunity to strangers unfamiliar with Devonshire to become acquainted with Torquay and its immediate neighbourhood. Any member who may wish to favour them with his presence, will oblige by notifying the same at

his early convenience—and not later than on the Wednesday of the Plymouth meeting—to the Honorary Secretary, Dr. Powell, Infirmary, Torquay.

**SPECIAL RAILWAY ARRANGEMENTS.**—First and second class ordinary and express return tickets issued at any Station on the Bristol and Exeter Railway, or on the South Devon, Cornwall, or West Cornwall Railways, on August 7th and following days, will be available for the return journey to and from Plymouth any day up to and including Monday, Aug. 21st. First and second class return tickets, at single fare for the double journey, available as above, may be issued from any Station on these lines to Plymouth, or from Plymouth to any South Devon, Cornwall, or West Cornwall station, on August 7th and following days to August 21st inclusive, to the members of the *British Medical Association* producing a certificate or the Association card of membership. Unless such documents be produced, return tickets at ordinary or express fares must be issued. When tickets at single fare for the double journey are issued, the booking clerks must write "return" upon them, and place their initials below the word "return". Ordinary tickets endorsed "return" will be available by express trains without payment of the difference of fare. The South Devon, Cornwall, and West Cornwall Railways have also promised to convey any instruments, medical and surgical appliances, etc., for the Annual Museum, at half the usual fares, at the owner's risk.

The Great Western Railway will issue Tourist Tickets for Plymouth, available for one month, to individual members of the Association on presentation of the card of membership. In ordinary circumstances, Tourist Tickets are issued only to parties taking two tickets.

**EXCURSIONS, ETC.**—The Local Committee appointed by "The Three Towns", Plymouth, Devonport, and Stonehouse, to prepare for the annual meeting of the British Medical Association in 1871, have much pleasure in acquainting the members that they have succeeded in obtaining the cordial cooperation and assistance of the civil and military authorities; so that every facility will be furnished them for inspecting this naval and military arsenal; Her Majesty's ships of war in the Hamoaze and Plymouth Sound; Her Majesty's dockyards at Devonport and Keyham; the Royal William Victualling Yard and the naval and military hospitals in Stonehouse; the Breakwater and its lighthouse; the Eddystone Lighthouse; the Plymouth Citadel, the Hoe, and the forts recently erected within a radius of five miles.

By the kind permission of His Grace the Duke of Bedford, the Right Honourable the Earl of Mount Edgumbe, the Earl of St. Germans, and the Earl of Morley, and other gentlemen, opportunities will be offered to the members of surveying the grounds and the extensive views commanded in the parks attached to their mansions on the banks of the Tamar and Plym; whereby they will be enabled to pass in review the objects before-named, as well as the magazines at Bull Point; Antony House, the seat of W. H. Pole-Carew, Esq., whereat is preserved Holbein's portrait of Dr. Butts, Physician to Henry VIII; Ince Castle, the residence (*temp.* Charles II) of the Wit of Cornwall, Killebrew; St. German's Church, the site of Cornwall's ancient Cathedral, and Port Eliot (the ancient Priory); Trematon Castle, the residence of the Norman Earls of Cornwall; the late Brunel's master-piece, the Royal Albert Bridge at Saltash; Landulph Church; Buckland Abbey, the seat of Drake, the great circumnavigator; Maristowe; Cothele House; Pentillie Castle; Morwell Rocks; Harewood, the scene of the fair Elfreda's treachery; and other objects of interest in a trip of twenty miles by steamboat.

A steamer will be engaged to make short trips daily, and at stated hours, during the visit of the Association, thus enabling those members who may not be desirous of hearing the delivery of certain papers, to spend their time agreeably in viewing the rich scenery of the port of Plymouth.

Other excursions will be arranged, with the sanction of the Directors, etc., of the Railway—to Launceston Castle, the Ancient Cornish stronghold; to the Saxon Abbey at Tavistock; to Endsleigh Cottage; and to the wild and romantic scenery of Dartmoor.

**ANNUAL MEETING.**—The "Annual Museum" of this Association will be open during the four days of the meeting, for the exhibition of:

1. The latest inventions in medical and surgical instruments and appliances of every kind. Also, for the special exhibition of ancient and modern fracture apparatus, or diagrams of such, thus setting forth the history of the treatment of fractures from the earliest records down to the present day.
2. New drugs and their preparations.
3. New articles of diet for invalids.
4. Pathological specimens; also photographs, casts, etc., illustrating disease.
5. New works on medicine, surgery, etc.

6. Models or drawings of any object of professional interest not included in the above list.

**Notice to Exhibitors.**—Application should be made as soon as possible; at the same time giving a list of the objects to be exhibited, and mentioning the space required. All objects sent must have a description attached. Parcels for the Museum should be addressed—"British Medical Association, the Assembly Rooms, Royal Hotel, Plymouth; care of H. Greenway, Esq." They must be delivered on or before July 31st, and be removed within three days after the termination of the meeting. Expenses of carriage and all risk must be borne by the exhibitors. All instruments and other articles intended for the Local Museum will be conveyed at owners' risks for half the usual fares on the Bristol and Exeter, South Devon, and Cornwall lines of railway. A card, bearing the name and address of the exhibitor, must be enclosed in each package, ready to be fixed on the outside. All communications respecting the Museum to be addressed to "Henry Greenway, Esq., Surgeon, Plymouth", the Secretary for that department.

**PAPERS.**—The following papers have been promised.

Tilbury Fox, M.D. 1. Hydroa. 2. A Note on Phtheiriasis, erroneously styled Prurigo.

J. Crichton Browne, M.D. Syphilis and Insanity.

J. Althaus, M.D. Paralysis of the Bladder, and its Treatment by the constant Galvanic Current.

T. J. Austin, M.R.C.S. Medical Electrification.

Thomas Littleton, M.B. The Effects of Submarine Descent on Man, and the Limits of his Capability.

William Roberts, M.D. Intemperance as a Cause of Chronic Bright's Disease.

W. H. O. Sankey, M.D. The Relation and Diagnosis between General Paresis and Locomotor Ataxy.

D. De Berdt Hovell, F.R.C.S. 1. The different Therapeutic Indications of Rheumatism and Neuralgia: with Remarks on Rheumatism as a Sequela of Diphtheria. 2. Uterine Truss or Support for *Post Partum* Hæmorrhage.

George Southam, F.R.C.S. Excision of the Tongue.

Edward Lund, F.R.C.S. Antisepticity in Surgery.

Furneaux Jordan, F.R.C.S. The Extension of Inflammation from the Epididymis to the Urethra: with Cases.

Thomas Beatty, M.D. 1. Fibro-cystic Disease of the Uterus. 2. The Radical Cure of Retroflexion of the Uterus.

Robert Barnes, M.D. Hypertrophic Elongation of the Cervix Uteri.

J. Braxton Hicks, M.D., F.R.S. 1. A Rare Form of *Post Partum* Hæmorrhage. 2. The Reduction of Inversion of the Uterus: illustrated by six Cases.

E. J. Tilt, M.D. Hysteria, and the various ways in which it has been viewed by Pathologists.

A. Meadows, M.D. The Treatment of Fibrous Tumours of the Uterus.

J. G. Swayne, M.D. Treatment of Hæmorrhage arising from Retention of the Secundines after Abortion.

Thomas Underhill, M.D. The Treatment of certain Cases of Placenta Prævia and of *Post Partum* Hæmorrhage.

J. G. Davey, M.D. Jenner and his Teachings.

Dr. Merrifield, Ph.D. The Meteorology of Plymouth for the last six years.

Cornelius Fox, M.D. The Estimation of Atmospheric Ozone by means of Aspirators and Acids.

J. W. Eastwood, M.D. Alcohol in Health and Disease.

R. Elliot, M.D. Life-Insurance Offices and Medical Fees.

William Ogle, M.D. Medical Reform personal, not parliamentary.

V. Jagielski, M.D. Koumiss: a Dietetic Remedy.

T. Clifford Allbutt, M.D. The Lesions of Enteric Fever as the Occasional Cause of a Permanent Injury to Nutrition.

C. B. Nankivell, M.D. The Provision of Medical Attendance on Independent Poor by Provident Dispensaries.

Arthur Ransome, M.D. The Respiratory Movements in Health and Disease.

J. T. Maunsell, M.B. Poor-law Medical Relief.

J. F. Payne, M.D. The Nervous Origin of certain Cutaneous Affections.

H. J. Alford, M.B. Loose Cartilages removed from Knee-joints.

J. Ingleby Mackenzie, M.D. The Climate of Sidmouth, with Meteorological Observations, 1865-1870.

Charles Steele, F.R.C.S. Excision of the Scapula.

Rawdon Macnamara, M.D. The Mode of Curing Anæmia by Compression; illustrated by the exhibition of Instruments employed for that purpose in Ireland from the earliest date up to the present time.

- George Johnson, M.D. The Pathology and Treatment of Cholera.  
 Henry Smith, F.R.C.S. Stricture of the Urethra, and its Treatment by Potassa Fusa.  
 Christopher Heath, F.R.C.S. The Treatment of Stone in the Female.  
 W. J. Square, F.R.C.S. Loose Cartilages, and the Removal by Subcutaneous Incision.  
 William Square, M.R.C.S. The Influence of Nerves on the Repair of Fractures.  
 S. M. Bradley, F.R.C.S. The Unity of the Syphilitic Virus.  
 J. H. Aveling, M.D. Arsenic in Menorrhagia and Leucorrhoea.  
 Robert Barnes, M.D. On so-called Emmenagogues, Abortifacients, and Oxytocics.  
 Protheroe Smith, M.D. 1. Supplemental Mechanical Force during Parturition, regulated by a Dynamometer.—2. A Successful Method of Treating certain Cases of Dysmenorrhoea and Sterility.  
 A. Wynn Williams, M.D. The Treatment of Cancer of the Neck of the Uterus and Allied Structures by the Injection and Application of Bromine.  
 Wilson Fox, M.D. The Successful Treatment of Cases of Acute Rheumatism, with an excessively High Temperature, by means of Cold applied externally.  
 Lawson Tait, F.R.C.S. 1. Obscure Effects of Tertiary Syphilis.—2. Diagnosis of Cancer of the Fundus of the Uterus.  
 R. W. Crighton, M.D. The Value of the Sulphate of Iron as a Local Application in Phlegmasia Dolens.  
 Henry Greenway, M.R.C.S. 1. The Value of Suspension in Surgery.—2. A New Mode of Hospital Construction.  
 David Davies, M.R.C.S. 1. The Difficulties and Trials of a Health Officer.—2. The Training, Qualification, and Duties of Nuisance Officers.  
 John Murray, M.D. (Inspector General). On Cholera.  
 Jonathan Hutchinson, F.R.C.S. 1. Some New Applications of Felt for Splints.—2. Diseases of the Skin following Vaccination.  
 Morell Mackenzie, M.D. Laryngeal Growths; the Comparative Advantages of their Removal by Laryngoscopic Treatment and Direct Incision into the Larynx.  
 C. A. Gordon, M.D., C.B., Deputy Inspector-General. The Prussian Siege of Paris, in some of its Relations to Hygiene and Surgery.  
 J. Hughlings Jackson, M.D. Tumour of the Middle Lobe of the Cerebellum.  
 Robert Martin, M.D. Intemperance as a Predisposing Cause of Cholera.  
 Benson Baker, M.R.C.S. Improvements in the Poor-Law Medical Service as a means of Economy in the Treatment of the Sick Poor.  
 J. A. Bolton, M.D. The Active Treatment of Acute Rheumatism and Gout.  
 J. Henry Bennet, M.D. Spain and its West Parts.  
 E. Long Fox, M.D. Tuberculous Phthisis.  
 William Hope, Esq., V.C. Sewage Irrigation considered in connection with Public Health.  
 T. J. Dyke, F.R.C.S. On the Modes of dealing with Outbreaks of Pestilential Fevers, sanctioned by the Health Authorities of Merthyr Tydfil.  
 William R. E. Smart, C.B., M.D., R.N. 1. Notes on the Institutions for the Relief of the Sick, Wounded, and Disabled of the Royal Navy.—2. On Injury of the Axillary Artery occurring in Artillery Practice.  
 Gentlemen desirous of reading papers, cases, or other communications, are requested to forward the titles to the General Secretary, or to one of the Secretaries of the Sections in which the paper is to be read. All papers should be forwarded to one of the above named officers on or before the 1st of August.  
 No paper must exceed twenty minutes in reading; and all subsequent speakers must not exceed ten minutes.  
 All speeches at the General Meeting must not exceed ten minutes each.  
 T. WATKIN WILLIAMS, F.R.C.S., General Secretary.  
 13, Newhall Street, Birmingham, July 15th, 1871.

#### CUMBERLAND AND WESTMORLAND BRANCH: ANNUAL MEETING.

THE annual meeting of the Cumberland and Westmorland Branch was held at the Bush Hotel, Carlisle, on Wednesday, July 12th, 1871. Dr. P'ANSON of Whitehaven occupied the Chair. Twenty-two members and visitors were present.

*New Members.*—Dr. MacBean (Annan) was elected a member of the Branch; and Dr. Thos. Sayer of Kirkby Stephen was elected a member of the Association and Branch.

*Report of Council.*—The Secretary then read the report of the Council as follows.

The Council of the Cumberland and Westmorland Branch of the British Medical Association, in submitting their third annual report, cordially congratulate the members on the prosperous condition of the Branch. At the present time, it numbers seventy members, showing an increase of one member over last year's list. During the past year, six new members have joined the Branch; two have died—Mr. J. B. Wilson, of Whitehaven, and Dr. Blaides, of Shap; and three have left the district.

Since the last annual meeting, there have been two general meetings of the Branch—the autumnal meeting being held at Keswick, and the spring meeting at Kendal. As this was the first time that either of these places had been visited by the Branch, the Council were somewhat anxious as to the result, and were much gratified at the successful and agreeable character of these meetings. The meetings were well attended, papers of a high standard of merit were provided, and good discussions followed the reading of them.

Since the last annual meeting, little progress has been made in medical reform. The Bill introduced by the Government last year was withdrawn on account of the opposition offered by the British Medical Association—an opposition in which, it will be remembered, this Branch took an active part. The Bills introduced by private members during the present session were not well supported, and had little chance of success. The Government hope to undertake the charge of the subject next year, and some settlement of the question may be anticipated.

The prizes open to the profession for essays on professional subjects are few in number, and the honour of obtaining one is greatly coveted. The Council have a pride and pleasure in stating that during the past year two gold medals have been awarded to members of this Branch for essays on subjects in Therapeutics. Dr. Clouston having obtained the Fothergillian Medal of the Medical Society of London, and the adjudicators of the Hastings Medal of the British Medical Association have just decided in favour of Dr. J. M. Fothergill. The Council warmly congratulate these gentlemen on their well merited honours.

It is a matter of deep regret that great irregularity prevails in the payment of subscriptions, and that in consequence a large amount of arrears are due to the Association. The subject has been frequently under consideration at meetings of the Committee of Council, and a plan has been approved which the Council of this Branch recommend for adoption. Circulars will be sent out four times in each year intimating to those who are in arrear the amount of their subscriptions due, and it is hoped that immediate attention will be given to the request contained in the circular.

The Committee on Clubs and Benefit Societies, appointed two years ago, has never presented a report.

*Treasurer's Statement.*—The balance in hand from last year was £5:5:4; subscriptions since received amount to £6:2:6; total, £11:7:10. The expenditure has been £6:16:8, leaving at the present time a balance of £4:11:2.

On the motion of the PRESIDENT, seconded by Dr. HEAD, the report was unanimously adopted.

*Votes of Thanks* were then accorded to the retiring President, the Secretary, and other members of Council for their services; and the retiring President, Dr. P'ANSON, was elected Vice-President.

*Office-Bearers.*—The following gentlemen were elected as office-bearers for ensuing year, viz: *President-elect*, T. S. Clouston, M.D. (Carlisle). *Honorary Secretary and Treasurer*, Henry Barnes, M.D. (Carlisle). *Members of Council*: R. Tiffin, M.D. (Wigton); M. W. Taylor, M.D. (Penrith); W. Reeves, M.D. (Carlisle); T. F. P'ANSON, M.D. (Whitehaven); W. T. Greaves, Esq. (Penrith); H. Hodgson, M.D. (Cockermouth). *Representatives of Branch on the General Council*: J. M. Fothergill, M.D.; R. Elliot, M.D.; T. S. Clouston, M.D.; and H. Barnes, M.D., *ex officio*.

*President's Address.*—The retiring President then vacated the Chair, and introduced the President for the year, R. Elliot, M.D., who delivered an inaugural address. Having alluded to the inauguration of the Branch at Carlisle in 1868, by its first President, Dr. Barnes, who genially and graphically contrasted the relative position of the medical profession to the public fifty years ago and now; and having referred to the following general meeting at Penrith, under the presidency of Dr. Taylor, who gave an admirable epitome of the History of Medicine; and to the meeting of last year at Whitehaven, when Dr. P'ANSON delivered a valuable address on the principal discoveries and improvements in medicine and surgery during the two preceding years, especially on thermometry and anaesthetics—the Chairman proposed, on this the fourth meeting, to dwell on the aims of the British Medical Association, and on the great influence for good which the profession acquired by such

organisation, particularly in reference to what is termed State Medicine. The Parent Association numbers, he said, 28 per cent. of the profession in Great Britain. This Branch boasts of 63 per cent. of the practitioners in Cumberland and Westmorland, a higher figure than that of any other branch. By the Association's second rule, the object is stated to be twofold; viz., to promote medical art-science, and to maintain the honour and interests of the profession. Under the first of these, may, with pride, be recorded the fact that, this year the Fothergillian Medal has been gained by Dr. Clouston, the President-elect, and the Hastings Prize by Dr. J. M. Fothergill, a representative of this Branch at the forthcoming meeting at Plymouth. Dr. Clouston has published an admirable paper on Neurotics; Dr. Taylor has importantly added to our knowledge of the propagation of infectious disease; and Mr. W. L. Dickinson of Workington has published several cases of trichinosis successfully treated, being the first observed and recorded in Britain, although forty years have elapsed since the first discovery of the flesh-worm in the subjects of a London dissecting-room. The second object, however, is no less important; and it has been not less efficiently exemplified by the organisation of the Parent Association, as well as by that of this Branch. Isolation or seclusion is ruinous to good feeling, just as association is abundantly and lastingly promotive of it. Let the profession in small towns, in this respect, be compared with our brethren in large cities, and the transcendent importance of the Association in obliterating prejudice and establishing friendship becomes undeniable. To the majority, this feature is probably the more important of the two. It may truly be said that, "singly we fall, united we stand!" We can thus consolidate and utilise our influence wherever our case is demonstrably good, so as to influence the public and the legislature. In State Medicine, this is essential. Individuals, unsupported and ununited, are simply powerless in restraining those vilest forms of wickedness by which the public are victimised, and property, health, and life destroyed; all of which social evils it is the object of State Medicine to abate, if not to annihilate. Quackery, the adulteration of food and medicines, and the tacit but obstinate maintenance of agencies, destructive alike of morals and health and life, under the specious plea of "vested interests," are amongst the chief objects against which State Medicine determinedly and philanthropically directs her shafts; these shafts can only be shot from a bow of resistless power—of a power far beyond that of any individual in a free country like ours. A despot, mighty alike in intellect and in will and power, like the great Napoleon, is the rare or unique example of an individual equal to the stupendous effort. In a nation such as ours—"great, glorious, and free"—such feats, by any individual, are plainly impossible. The Gordian knot, however, may be cut by means of organisation, such as that presented by the British Medical Association. Great, then, is the promise of the Association, in reference to the beneficent administration of State Medicine; and greater is the responsibility of those members of our profession who refrain from joining and aiding in this truly great work. The prevention of evil is proverbially better, and in fact it is easier, than the cure. To the wise and the good, a word is enough. Of all professions appertaining merely to this life, it has been wisely and eloquently said by the great Roman orator Cicero, that "man never so nearly approaches the character of the divine, as when giving health to men." This is conspicuously true of our profession under all circumstances, but it is eminently and peculiarly so in our relation to State Medicine; with the lofty and disinterested object of mitigating, and even of extinguishing, those appalling epidemics which, at intervals, decimate a nation; and of removing from our midst, those constant causes of permanent degeneracy and premature decay and death which afflict mankind generally, but most noticeably so in the poverty-stricken districts of large cities. State Medicine is not of recent date. In the Mosaic dispensation it had the highest importance assigned to it. The ancient Romans cultivated it. We are annually more and more appreciating its vital importance. Our peculiar education adapts us for its cultivation, and we must prove ourselves equal to the emergency.

*Papers.*—1. Mr. SINGLETON (Kendal) read a paper on the Treatment of Infantile Convulsions, and endeavoured to show how fallacious our treatment must be if convulsion be viewed as a disease, and not recognised as a mere symptom. Convulsions in children mostly had their source in causes "eccentric" or sympathetic of irritation elsewhere, and there were many symptoms to distinguish the convulsive state so dependent from convulsion due to central causes, the principal being the peculiar form of vomiting. The convulsion caused by the presence of undigested or improper aliment was by far the most frequent and most powerful, and was accompanied with profuse perspiration. The treatment of all forms of convulsions in infants must solely depend on the diagnosis as to the probable cause, ignoring the existing convulsion, save as a symptom merely. Infantile convulsions (due to causes eccentric), excepting teething (when large doses of conium, and not the

gum-lancet, should be employed), and convulsion where a vermifuge was indicated, were best treated by the administration of emetics; the most suitable emetic being ipecacuanha powder. And it was to be observed that ipecacuanha, when given as an emetic to young children, must be given in extremely large doses, as children tolerated the action of this drug relatively to a much greater extent than in adults. Convulsions occurring in tubercular meningitis he treated by counterirritation to the shaven scalp induced by croton oil; and he had observed that belladonna, of all sedatives, was the most reliable, through its power of diminishing the cerebral circulation.

2. Dr. MACLAREN (Carlisle) read a paper on the Treatment of Small-Pox by the Local Exclusion of Light. He pointed out that the treatment of this disease by keeping the cases in darkness had been attended with good results in preventing fever primary and secondary, and that it had the disadvantages of making ventilation and cleanliness difficult, and, it was said, of rendering mortality high. It was next stated that, from the time of Rhazes until the present period, the applications which had acquired the credit of preventing pitting were such as excluded light or its actinic rays. As proof that light favoured pitting, the absence of cicatrices in recorded cases of intrauterine variola was alluded to. And in conclusion, the writer mentioned the favourable results in preventing secondary fever and pitting which had attended the use of a light-excluder composed of collodion or gutta-percha and India-rubber dissolved in chloroform, to both of which was added lamp-black; this being freely applied to the parts of the body exposed to light, and it was suggested that sun-light strained through a yellow medium to exclude chemical rays was deserving of trial.

*Dinner.*—After the discussions on these papers had ended, the dinner hour had arrived, and the meeting was unable to take into consideration the third paper on the list—one by Dr. M'Gregor of Penrith. Eighteen gentlemen sat down to dinner, the President, Dr. Elliot, occupying the Chair, and Dr. P'Anson the Vice-chair.

#### METROPOLITAN COUNTIES BRANCH: ANNUAL MEETING.

THE nineteenth annual meeting of this Branch was held at the Castle Hotel, Windsor, on Friday, February 14th, at 3 P.M. The Chair was taken by the retiring President, T. HECKSTALL SMITH, Esq.

*Report of Council.*—Dr. STEWART, one of the Honorary Secretaries, read the following report.

In presenting this Report to the Metropolitan Counties Branch, at this its nineteenth annual meeting, your Council have to state that the numerical strength of the Branch remains nearly the same as it was last year. At the annual meeting in 1870, the number of members on the list was 368. Since that time, nine members have died, and thirteen have retired. Twenty new members have been added, making the total number at present 366.

The members who have died during the year have been: Mr. Lionel J. Beale; Mr. W. J. Clement, M.P. for Shrewsbury; Mr. John Dow; Mr. John Evans; Dr. William Griffith; Dr. John Hatton; Mr. Samuel Norway; Dr. John R. O'Brien; and Dr. T. H. Tanner. Of these, Dr. John Hatton deserves to be held in grateful memory by the Association, of which he was long a highly meritorious officer, having for fourteen years diligently and efficiently performed the duties of Honorary Secretary to the Lancashire and Cheshire Branch.

Notwithstanding the apparently large number of members of the profession included in the Branch, there are still many members of the Association in the district who have not yet joined our ranks. Your Council would take the present opportunity of impressing on the members of the Branch the importance of individual exertion so as to induce their friends to join. The diffusion of circular letters for the purpose of disseminating a knowledge of the advantages of membership both of the Parent Association and of the Branch does a certain amount of good; but your Council cannot but agree thoroughly with the opinion of the Council of the Birmingham and Midland Counties Branch "that more success is likely to follow the personal representation by its members of the advantages to such professional friends as they can influence, who do not yet belong to the Association and the Branch."

Your Council have little to report on the subject of Medical Reform. The settlement of the question is still unfortunately a thing *optandum magis quam sperandum*. At the last annual meeting, the Branch resolved that a petition should be presented to Parliament in favour of the Direct Representation of the Profession on the Medical Council, and of the restitution to the Bill then before Parliament of the clause which restricted the medical authorities from conferring their diplomas and licenses to practise independently of the central examining boards which it was proposed to form. The Bill, for reasons which have been

fully explained in the JOURNAL and elsewhere, was soon afterwards withdrawn. Nothing in regard to medical legislation has since occurred to call for action on the part of the Branch. Some of its members have seats in the Medical Reform Committee of the Association; and your Council are assured that these gentlemen will not fail to give warning at the proper time when it may become necessary for the Branch to act in its collective capacity.

In lending its aid to the Direct Representation Committee in its endeavours to secure the amendment of the Government Bill of last session, and so indirectly procuring the withdrawal of that, in many respects, useful measure, the Council feel that they and the members of the Branch who in large numbers signed the petitions of last year, have not incurred any responsibility which they need for a moment hesitate to accept. Those who opposed the Bill have been, and are, freely charged with having taken upon themselves a very serious responsibility in causing the postponement even for a single year of a measure which would have been an incalculable boon to the whole community. To this the ready and conclusive answer is, that the profession and the public have been deprived of this great boon since 1858, when the British Medical Association earnestly strove to confer it upon them, by the influence of those who now reproach us with a selfish and obstructive policy; and that, since these critics have been so long in finding out the virtues of the Association's original measure, and would have been content to do without it still longer, had not the Government compelled them to accept it, the Association is fully justified in preferring a brief additional delay to an imperfect measure which would require amendment or reconstruction a few years hereafter. That the Association many years ago earnestly maintained the very principles which are now held to be the only admissible basis of a satisfactory Medical Act, is surely the best of all practical arguments why the general body of the profession should be directly represented in the Medical Council. And to have consented to the enactment of the Government Bill, which perpetuated the old and faulty constitution of the Council, on the promise of a select committee to inquire into the propriety of granting that which we hold to be a *sine qua non*, would have been in the last degree inconsistent and suicidal.

There have been three ordinary meetings of the Branch during the spring months. The attention of the members and others who attended these meetings was directed on each occasion to questions full of interest and importance, both professional and social. The reading, by Mr. Fairlie Clarke, of a very able paper "On the Medical Aspects of Pauperism," drew together on March 3rd a large audience, and elicited a spirited discussion, in which Sir Charles Trevelyan, Mr. Corrance, M.P., Mr. W. H. Smith, M.P., Mr. Shaw Stewart, and Mr. Alsager Hay Hill took part. The direct result of this meeting was the formation, in connection with the Society for organising Charitable Relief in the Metropolis, of a medical Subcommittee which, in a series of meetings held from week to week, addressed itself to the task, which it has nearly accomplished, of drawing up a code of rules for the guidance of those who seek to establish provident dispensaries both in town and country districts. Dr. J. Ford Anderson, Mr. Fairlie Clarke, Dr. Hawksley, Dr. Heywood Smith, and Dr. Stewart are members of that Subcommittee. That this important social question, and the closely allied one of the remuneration of medical men for the vast amount of hitherto unrequited service rendered by them to the public, will now attract the attention which has too long been denied to them, your Council see no reason to doubt; and they feel that the Branch may fairly congratulate itself on having been so directly instrumental in giving so decided an impulse to a movement which, after having repeatedly gathered strength and languished again during the last thirty years, promises now to be crowned with success. Nor is this either the first or the second time within the last ten years—witness the successful struggle for securing the rights of the medical officers of the United Service, and the movement which ended in the appointment of the Royal Sanitary Commission—that this Branch has had the honour of bearing an early and conspicuous part in the assertion of principles which have, in the long run, triumphed over all opposition. On April 2nd, another large audience assembled to hear a highly instructive and seasonable paper from Dr. Edward Cator Seaton, "On some of the Lessons to be derived from the present Epidemic of Small-pox." That paper, published in the JOURNAL, has been extensively read, and has, your Council have reason to know, been received with gratitude throughout the country. The third ordinary meeting, having been unfortunately summoned on May 24th, and having thus to compete with the attractions of the great Epsom festival, was necessarily limited in numbers; and Dr. Stewart's paper "On Sanitary Organisation as viewed by the Joint Committee of the British Medical and Social Science Associations, the Royal Commission, and the Government," had not the effect which it was hoped it might have, of eliciting from a large concourse of

members of the Branch and of public men, a full expression of opinion in regard to the measures that have been proposed for adoption by the Imperial Parliament.

The Parliamentary Bills Committee is once more, your Council are happy to say, in active operation. Owing to some oversight of the central authority, the non-appointment till late in the spring of the General Committee enjoined by the meeting at Newcastle, rendered necessary the appointment by your Council of a provisional Committee early in the session, to look after those Bills which affected the interests of the medical profession. This Committee, either by itself, or in conjunction with the more recently appointed representatives of the other Branches, has been quietly but effectually carrying out the work committed to its care.

It has been represented by several members, that it would be desirable to make certain alterations in the constitution of the executive body of the Branch, with the view of increasing its efficiency. Your Council have taken the matter into careful consideration at several meetings, and have agreed to recommend for the approval of the Branch alterations in the laws which will, if carried, limit the tenure of office of ordinary members to three years, and will increase their number from twelve to eighteen. Your Council are also of opinion that a new law should be introduced, to give the Branch the power—if such a course should at any time be necessary—of expelling a member proved guilty of professional impropriety or misconduct.

Mr. LORD moved, and Dr. GEORGE WEBSTER seconded—"That the Report of Council now read be received and adopted." Some discussion regarding the proposed alteration in the laws followed, in the course of which it was explained that a special general meeting for their consideration would be called in October. The resolution was adopted.

*Treasurer's Report.*—Mr. DUNN, Treasurer of the Branch, presented his report. The income of the Branch for the year amounted to £61:11:9, and the expenditure to £44:13:9, leaving a balance in hand of £16:18:0.

Dr. WYNN WILLIAMS proposed "That the Treasurer's report be received, adopted, and entered on the Minutes." Dr. FELCE, in seconding the resolution, thanked the Branch for its donation of five guineas to the Medical Benevolent Fund, which formed one of the items of expenditure for the year. The resolution was carried.

*Election of Officers and Council.*—The ballot having been taken, the following gentlemen were declared elected the officers and Council of the Branch for the ensuing year. *President*, J. Russell Reynolds, M.D., F.R.S. *President-elect*, Sir William Fergusson, Bart., F.R.S. *Vice-Presidents*: George Johnson, M.D.; T. Heckstall Smith, Esq. *Treasurer*, Robert Dunn, Esq. *Secretaries*: A. P. Stewart, M.D.; Alexander Henry, M.D. *Ordinary Members of Council*: Benson Baker, Esq.; William Bartlett, Esq.; W. C. Begley, M.D.; Samuel Day-Goss, M.D.; J. E. Erichsen, Esq.; G. A. Ibbetson, Esq.; Henry Lee, Esq.; Richard Quain, M.D., F.R.S.; William F. Ramsay, M.D.; C. H. Rogers-Harrison, Esq.; James D. Rendle, M.D.; Joseph Seaton, M.D.

Mr. HECKSTALL SMITH, in resigning the chair as President, said that his duties during the year had not been onerous, but the performance of them had afforded him much pleasure and gratification. He had been highly gratified with the position in which he had been placed by the Branch. All the important points alluded to in the Report of Council affected the Association as well as the Branch. The general interest centred in medical reform. He was one of those who thought that it was best to defer the settlement of the question until a complete measure could be obtained.

Dr. RUSSELL REYNOLDS, on taking the chair, thanked the members for the honour conferred on him, and delivered an address.

*Vote of Thanks.*—Mr. W. RIVINGTON moved, Dr. W. DICKSON seconded, and it was unanimously resolved—"That the cordial thanks of the meeting be given to the President for his able address, and that he be requested to allow its publication in the BRITISH MEDICAL JOURNAL."

Dr. STEWART moved, and it was carried by acclamation—"That the cordial thanks of the Branch are due to the retiring President, Thomas Heckstall Smith, Esq., for his able and courteous conduct in the chair, and for the warm interest which he has always manifested in the prosperity of the Branch."

*Representatives in the General Council.*—The following members were chosen to represent the Branch in the General Council of the Association: J. H. Aveling, M.D.; S. Day-Goss, M.D.; Stamford Felce, M.R.C.P.Ed.; C. H. Rogers-Harrison, Esq.; Ernest Hart, Esq.; C. Heath, Esq.; A. Henry, M.D.; Berkeley Hill, Esq.; G. Johnson, M.D.; Henry Lee, Esq.; C. F. J. Lord, Esq.; W. Martin, Esq.; J.

Murray, M.D.; R. Quain, M.D., F.R.S.; G. P. Rugg, M.D.; J. Seaton, M.D.; E. J. Tilt, M.D.; A. W. Williams, M.D.

*Dinner.*—The members and their friends, to the number of forty-six, afterwards dined together at the hotel; the President, Dr. Russell Reynolds, occupying the chair.

#### BATH AND BRISTOL ANNUAL MEETING.

THE annual meeting of this Branch was held at the Bristol Museum and Library on Thursday, July 13th, at 4.45 P.M. C. H. COLLINS, Esq., took the Chair in the absence of the President, CHARLES BLEECK, Esq. There were present 43 members.

Mr. COLLINS said that he was sorry to have to inform the meeting that Mr. Bleeck was unable to attend, in consequence of an accident that he had met with some days before. Mr. Collins then resigned the Chair to CROSBY LEONARD, Esq.

*President's Address.*—After thanking the members of the Branch for the honour conferred on him in his appointment, the President referred to the great numerical increase during the last few years in the Association, and urged upon the members present to endeavour to add to the strength of the Association and its Branches by pointing out and advocating the advantages, both professional and social, which Branch membership afforded. Passing on to short obituary notices of deceased members of the Branch, including four ex-Presidents, he referred at considerable length to the lamented death of Dr. Symonds. Amongst the subjects treated of in the address were: The Sanitary State of Bristol, indicating some of the easily preventable modes of propagation of infectious diseases; Medicine as a Scientific Profession; The Aims and Advantages of Public or State Medicine; Modern Therapeutics; and the Registration of Diseases.

Dr. DAVEY proposed a vote of thanks to Mr. Crosby Leonard for his very able address, which was seconded by Mr. COLLINS and carried by acclamation.

*New Member.*—Mr. E. Long of Thornbury was unanimously elected a member of the Branch and of the Association.

*Report of Council.*—Mr. BOARD, the Bristol Secretary, read the following report.

Your Council has much pleasure in being able to lay before you a satisfactory report of the past session. Although the Branch has unavoidably lost several members, its numbers have increased from 176 to 179 since the last annual meeting. Thus fourteen gentlemen have been elected members of the Branch, while five have left the neighbourhood, two have resigned membership, and four have been removed by death.

It is our painful duty to record the deaths of Dr. Symonds, Dr. Irvine Smith of Bath, Mr. Hore, and Mr. Lang. The loss of Dr. Symonds, an ex-President of the Association, is especially to be deplored, not only by the Association, but also by the whole medical profession. By his death the profession and the public lose a physician eminent for his perfect knowledge of his profession, and for his scientific and literary attainments. In him we lose a kind and courteous friend and neighbour, trustworthy in every sense, a jealous guardian of the honour of our profession—one ever eager to stretch out a helping hand to a brother in distress, and anxious, even in failing health, to devote himself unselfishly to the good of the profession. He was the author of many valuable papers read before the Branch; and in 1863, when the General Meeting of the Association was held in Bristol, he discharged the duties of President in a most able manner.

The Bristol Royal Infirmary and the Bristol General Hospital have each lost a former member of their staff in the persons of Mr. Hore and Mr. Lang. We may say for each that he carried on his professional career in the strictest and most honourable manner.

Twenty-one papers have been read during the session, and several have given rise to much discussion.

Mr. Church having retired from the Council of the Bath Branch, Mr. Waugh was elected to fill the vacancy, subject to approval at the annual meeting.

At the last meeting of the Branch, Dr. Davey was elected representative member for this Branch on the Parliamentary Committee of the Association.

The accounts of the Branch are in a most satisfactory condition, there being a balance in hand of £19:5:1. Under these circumstances, your Council recommends that the donation of £3:3 to the Medical Benevolent Fund, made last year, be repeated. An appeal on behalf of this valuable charity has been lately circulated through the courtesy of Somerset, Wiltshire, and Gloucester; and your Council has much satisfaction in stating that many new subscriptions have been received, as well as several donations from individuals who are not members of the medical profession.

The scrutineers report that the following gentlemen have been elected members of the Local Councils; For Bath: Messrs. Lawrence, Waugh, Skeate, and J. K. Spender, M.D.; For Bristol: Messrs. Prichard, W. M. Clarke, C. H. Collins, E. L. Fox, M.D., and W. Budd, M.D.

Mr. R. M. BERNARD proposed, and Mr. R. W. TIBBITS seconded, "That the Report now read be adopted."

*President-elect.*—Mr. R. N. STONE proposed, and Mr. R. W. COE seconded, "That T. G. Stockwell, Esq., be President-elect."

This was carried by acclamation.

*Vote of Thanks.*—It was proposed by Mr. P. CHADWICK, and seconded by Mr. S. H. SWAYNE, "That the best thanks of the Branch are due, and are cordially tendered, to Mr. Bleeck, the retiring President, and to the Council of the Branch, for their able conduct of the business of the Branch during the past year."

Dr. HENSLEY proposed and Dr. BRITTAN seconded, and it was unanimously resolved, "That the best thanks of the Branch be tendered to the Secretaries, Messrs. Fowler and Board, for their services as secretaries, and that they be requested to continue in office."

*Representatives in the General Council.*—The following gentlemen were appointed Representatives of the Branch on the General Council of the Association. F. Brittan, M.D.; E. L. Fox, M.D.; C. Harper, Esq.; C. Leonard, Esq.; F. Mason, Esq.; E. Skeate, Esq.; C. Steele, Esq.; J. G. Swayne, M.D.

The proceedings closed with a vote of thanks to the Committee of the Bristol Museum and Library for the use of the Reading-Room.

#### YORKSHIRE BRANCH: ANNUAL MEETING.

THE annual meeting of this Branch was held at the Infirmary, Bradford, on July 26th.

*Report.*—The President, Mr. MEADE, after making some remarks on the present state of medicine, called upon the Secretary to read the report, which drew attention to the fact that this was the first year that the annual meeting had been held at other places than York, Leeds, and Sheffield; and it was thought that by the adoption of this plan the usefulness of the Association would be retained and its advantages become more generally known. After the relation of work done during the year in the Branch, and some remarks on the proposed alteration of the Rules at Plymouth, the report went on to state that the Council hoped that members would aid the gratuitous labours of the Secretary in relation to the subscriptions by the payment of them in January of each year. The neglect of this practice materially affected the financial position, and increased the difficulty of managing the accounts, of the Association. After the discussion of some Branch matters of business, it was stated that the numbers of the members in the district amounted to 333, of whom 144 belonged to the Branch. Fourteen members have been added this year, and the vacancies occasioned by resignations and deaths have been eight.

Dr. CLIFFORD ALBUTT proposed, and Dr. EDDISON seconded, the adoption of the report, which was unanimously agreed to.

*President.*—It was proposed by Mr. HUSBAND, and seconded by Dr. BOMAR—"That the annual meeting for 1872 be held at Leeds; and that C. G. Wheelhouse, Esq., be elected President for that year."

*Branch Council.*—On the motion of Dr. HEATON, seconded by Mr. FOSTER, the following gentlemen were elected:—B. Dodsworth, Esq., J. H. Gibson, M.D., W. D. Husband, Esq., W. Matterson, M.D., S. W. North, Esq., G. Shann, M.D.—of York; C. Chadwick, M.D., J. D. Heaton, M.D., S. Hey, Esq., T. Scattergood, Esq., T. P. Teale, Esq., C. G. Wheelhouse, Esq.—of Leeds; J. Benson, Esq., W. Favell, Esq., J. C. Hall, M.D., J. Haxworth, Esq.—of Sheffield; R. H. Meade, Esq., of Bradford; J. Ness, Esq., of Hemsley.

*Representatives in the General Council.*—The following were elected: C. Chadwick, M.D.; R. T. E. Cooke, L.R.C.P.Ed.; J. C. Hall, M.D.; J. D. Heaton, M.D.; S. Hey, Esq.; S. Holdsworth, M.D.; W. D. Husband, Esq.; W. Matterson, M.D.; R. H. Meade, Esq.; G. Shann, M.D.; T. P. Teale, Esq.; C. G. Wheelhouse, Esq.; J. Hodson Wright, Esq.

*Secretary.*—On the motion of Mr. TEALE, seconded by Dr. NICOL, Dr. Procter was re-elected Secretary.

*Cases and Papers.*—1. Dr. CLIFFORD ALBUTT made remarks, which were illustrated by cases, on some forms of Paralysis.

2. Mr. TEALE read a paper on Mucous Fistula in Ann.

3. Mr. JESSOP exhibited two patients on whom he had performed Adams's operation for Division of the Neck of the Femur.

4. Mr. HAXWORTH communicated a case of Gangrene implicating the Lower Jaw.

*Dinner.*—The members and their friends afterwards dined at the Victoria Hotel.

## CORRESPONDENCE.

## THE BRITISH MEDICAL ASSOCIATION.

SIR,—A letter appears in the JOURNAL of this morning, from Mr. Hodgson, of Brighton, of so extraordinary a character, that I cannot allow it to pass altogether unnoticed. I shall not attempt to make any reply to it, but ask you to permit me to request the members of the British Medical Association to withhold their judgment upon the various questions therein raised, or, I may say, charges made by implication against the General Secretary, until the annual meeting.

It is an unheard of proceeding for a member of a Committee to publish any part of the proceedings of that Committee without consulting his colleagues, or at least the Chairman of the Committee. The *animus* of the writer is so unmistakable, that I feel silence on my part will be wisdom. I am, etc., T. WATKIN WILLIAMS, F.R.C.S.,  
*General Secretary, British Medical Association.*

13, Newhall Street, Birmingham, July 29th, 1871.

## ALTERATION OF LAWS.

SIR,—Among the alterations of laws to be considered at Plymouth, I observe that there are some which relate to the Council and Committee of Council; and I wish to call the attention of members—especially those from the metropolis and from Ireland and Scotland, and those belonging to the public services—to the following points bearing on the question.

The Council is now exclusively elected by the Branches, each Branch returning one representative for each twenty members on its roll, making a total of about 120; and so long as all, or nearly all, the associates were affiliated to Branches, this arrangement left nothing to be desired. But this is now far from being the case: a large proportion of members, amounting to about two-fifths, are unconnected with any Branch, and therefore unrepresented on the Council. In the lists published last year I find that the members affiliated to Branches numbered 2520, while the total number of associates (exclusive of foreign and colonial) was 4178. This discrepancy chiefly affects London, Ireland, and Scotland, and the members attached to the public services. Middlesex has 614 associates, while the Metropolitan Counties Branch has only 360 members. Scotland, Ireland, and the public services, supply 353 associates, but (having no Branches) do not send a single representative to the Council. The effect of this is permanently to exclude a large number of our most eminent associates from any share in the management of the Association; and the weight and authority of their names is in consequence, to a great extent, lost to the Society.

To illustrate the working of the present arrangement, I may mention a few well-known names who have been members for years, and who have taken a prominent part in the proceedings of our annual meetings, but who have not now, and, I think, never have had, a seat on the Council: Sir William Jenner, Dr. Gull, Sir W. Fergusson, Dr. Sharpey, Dr. Bowlshe, Mr. Spencer Wells, Sir H. Thompson, Dr. Sieveking, Mr. Bowman, Dr. Hughes Bennett, Professor Lister, Dr. Gairdner, Dr. Christison, Professor Haughton, Dr. Beattie, etc. On looking over the list of members, I find that almost every known name in the profession in the three kingdoms is enrolled among them, and yet only a thin sprinkling find their way into the Council. I can scarcely think that this state of things is the result of deliberate purpose, but that it arises from an overlooked defect in the method of electing the Council; at any rate, it will scarcely be denied that the Association suffers both in influence and in usefulness from the circumstance.

One of the alterations to be proposed by the President of the Council will slightly tend to diminish this anomaly; namely, that in which it is proposed to give seats on the Council for life to the Vice-Presidents of the Association. But this remedy only touches the fringe of the anomaly; and I would suggest that all the proposals relating to the Council be for the present postponed, and that a subcommittee be appointed at the Plymouth meeting to consider and report generally on the election and duties of the Council and Committee of Council, with a view of suggesting to the annual meeting of next year such a change in the laws as will remedy their defects. It would be easy to suggest means whereby the most glaring of them would be corrected. It might, for instance, be enacted that the readers of addresses, the presidents, vice-presidents, and secretaries of sections, shall have seats on the Council *ex officio*. Power might also be given to the Council to add a certain quota of names to its own numbers, either by its own authority or with the sanction of the general meeting. But I will not discuss these suggestions any further. If an opportunity be given me, I shall be ready to propose

the appointment of a subcommittee to consider the matter, as an amendment to the proposal of the President of the Council on Rule 7.

There are two other alterations of quite minor importance that clearly require to be made in Rule 8, which relates to the duties of the Council; namely, in Sections 5 and 6, which enact that the Council shall nominate the readers of addresses at the ensuing annual meeting, and that it shall determine the order of business at the general meetings. Both these functions are evidently more appropriate to the Committee of Council, and are, I believe, now so performed, the law to the contrary notwithstanding.

Manchester, July 29th, 1871.

I am, etc.,

WM. ROBERTS, M.D.

## THE MEDICAL DEPARTMENTS OF THE BRITISH AND AMERICAN NAVIES.

THE following correspondence, which has been handed to us for publication, will be read with interest.

Navy Department, Bureau of Medicine and Surgery,  
June 15th, 1871.

DEAR SIR,—I have been culpably negligent in not complying with the wishes of the United States Naval Medical Corps, earnestly urging me to make, on their part and my own, grateful acknowledgment to our brethren of Great Britain, and to you, sir, in particular, for the cordial, earnest, and effective support given in our struggle to secure in the Naval Service the just recognition due to our honourable profession. My only excuse for the delay of an agreeable duty has been the hope of seeing, as the confusion of the contest disappeared, clearly where we are. We know that in the legal recognition of true principles we have gained much, not only for our own good, but also for that of the service generally. We flatter ourselves that there is an increasing tendency to fraternity, and to give a just practical expression to the principles which have been established. This is the natural result of eliminating false and inharmonious principles from any organisation. If we have further difficulty, it will be because some fragments of wrong are yet left in the machinery.

Notwithstanding the very clear and definite testimony of the Hon. Captain W. J. Ward, R.N., Attaché of the British Legation, laid before the Senate Naval Committee, we failed, by some misconception, to reach the perfection of the Royal Navy as regards the first lieutenant or second executive officer; and in this failure lies the source of disturbance, unless it be met with that discretion upon all sides which cannot always be expected.

Your support gave us encouragement, and the assurance that we were not advocating a narrow and local interest, but one which interested the self-respect of all scientific and professional men labouring in military service.

Your sympathy was not the outspeaking of professional brotherhood only, but of that unconquerable instinct common to both our peoples, everywhere resisting to the end, and at all sacrifices, wrong and aggression, asserting our kinship of race, and aiding the progress of civilisation. I have every hope and confidence that in all such labours of progress we will be found working, as in the present cause, with all the earnestness and power of fraternal union.

Repeating the thanks of the United States Naval Medical Corps to yourself, and to all our brethren of Great Britain who gave us their friendly aid, I am, Sir, with great respect, your very truly,

WM. M. WOOD, Surgeon-General U.S. Navy.

Dr. Fred. J. Brown, Rochester, England.

Rochester, England, July 17th, 1871.

DEAR SIR,—It is with much satisfaction that I reply to your letter dated June 15th, acknowledging the sympathy and support afforded by officers of the British Navy and myself to our brethren in the United States Navy in their struggle for the rights of the medical profession. I am authorised by my brethren to accept these gracious acknowledgments, and to express through you, to the medical staff of the United States Navy, our hope that the profession may soon attain to its rightful status in the sea-service of the Great Republic.

I have the honour to be, dear Sir, yours truly,

FREDERICK JAMES BROWN.

To Dr. Wm. M. Wood, Surgeon-General U.S. Navy, Washington.

BOARDING-OUT OF PAUPER CHILDREN.—Thirty-one Committees have been formed, and Secretaries appointed, for providing homes with foster parents for orphan or deserted pauper children beyond the limits of the unions to which they are chargeable, under the provisions of the General Order of the Poor-law Commissioners, dated November 25th, 1870.

## OBITUARY.

CHARLES NEILSON, M.D., KILLALA, IRELAND.

DR. NEILSON died on July 15th, aged 74. He was a native of County Down, and received his education at the seminary of his grandfather, the Rev. Moses Neilson, D.D., Redemon. He early manifested a talent for languages, having been familiar with the Greek Grammar at the age of seven years. He had also a similar aptitude for medical science; and, when only twelve years old, he was able to amputate a limb in the Dundalk Hospital, where he was initiated in surgery under the late Dr. Noble. He studied in Dublin, and in 1824 took out his diploma in the Royal College of Surgeons. He was elected a Fellow of the College in 1844. He began as a practitioner in Killala, and, on the establishment of the Poor-law system in Ireland, became the medical dispensary officer of the Killala Union. During the lengthened period of forty-six years' practice, Dr. Neilson was most successful in each department of his profession, having won the confidence of all classes by his skilful treatment of disease; while his urbanity of manner, combined with a genial and liberal disposition, endeared him to a large circle in the community, who now mourn his removal. In the years 1832 and 1849, when cholera ravaged the district, he was most active and successful in his treatment of that terrible epidemic. He always manifested literary and scientific taste of a high order, and kept up an extensive reading in medical, theological, and modern literature. For several months past he suffered severely from acute disease of the heart, which terminated in his death.

JAMES HESTER, M.D.

DR. JAMES HESTER, who died at Wangaratta in Australia on May 1st, was the son of Mr. James Torry Hester, formerly surgeon to the Radcliffe Infirmary, Oxford. His early professional life was passed under the guidance of his father at the Infirmary; after which he was sent to St. Bartholomew's Hospital, where he gained and retained the esteem of the staff and many of his fellow-pupils. Having completed his education and passed his examination, he studied for some months in Dublin, residing at the Rotunda; and subsequently passed six months attending lectures and practice in Paris. On his return, finding his health precarious, he resolved to go abroad, and took charge of a ship to Australia. Having returned home, he for a short time joined his father in Oxford; but, his health again giving way, he went to Buenos Ayres. Not liking the place, he returned to England, and obtained an appointment in the Peninsular and Oriental service. He had a very severe attack of dysentery, and relinquished this appointment in about two years. He returned to England, and went to India, where he obtained a valuable medical appointment; this he was induced to leave in consequence of suffering very severely from jungle-fever. He then settled at Albany, Australia, where he was very successful; he returned, however, to England about three years ago, and, after spending a short time in this country, went to Switzerland, where he obtained the degree of Doctor in Medicine and Surgery—being, it is believed, the first Englishman who succeeded in doing so. In 1870, he again went to Australia, and settled at Wangaratta, where he made many friends, and was succeeding admirably in his profession, when he died, apparently of some intestinal obstruction terminating in rupture of the bowel. In his character, he evinced the greatest amiability. Wherever he went, he made friends; and he was esteemed by all who knew him.

HERBERT CHALMERS MILES, L.R.C.P. Ed.

RECENT intelligence from India brought to his family the painful intelligence of the death of Dr. Herbert Chalmers Miles, Surgeon Royal Artillery, aged 38. He was the only surviving son of John Miles, M.D., of Eastbourne, late of the Charterhouse. The deceased was educated at the Charterhouse School; and, after receiving his professional education at St. Bartholomew's Hospital, entered the army in 1854, and has since been in much active service. He was engaged during the Crimean war and during the Indian mutiny, receiving a gunshot wound at the siege of Moolwash, whilst under fire. He had the honour of being presented with three medals. After returning to England for some months, he was ordered to Nova Scotia, where he passed nearly two years. In December 1867, he was again ordered to India, where his short career terminated at Colaba, Bombay, on June 16th, 1871, after twelve days of acute illness. He was buried with military honours at Bowree Cemetery, on June 17th. His funeral was attended by the Royal Artillery and many officers of the 49th and 10th Regiments, besides many friends.

## MEDICAL NEWS.

### VACCINATION UNDER CONTRACT.

THE annexed revised Instructions to Vaccinators under Contract have just been issued by order of the Lords of Her Majesty's Council.

1. Except so far as any immediate danger of small-pox may require, vaccinate only subjects who are in good health. As regards infants, ascertain that there is not any febrile state, nor any irritation of the bowels, nor any unhealthy state of skin; especially no chafing or eczema behind the ears, or in the groin, or elsewhere in folds of skin. Do not, except of necessity, vaccinate in cases where there has been recent exposure to the infection of measles or scarlatina, nor where erysipelas is prevailing in or about the place of residence.

2. In all ordinary cases of primary vaccination, if you vaccinate by separate punctures, make such punctures as will produce at least four separate good-sized vesicles, not less than half an inch from one another; or, if you vaccinate otherwise than by separate punctures, take care to produce local effects equal to those just mentioned.

3. Direct care to be taken for keeping the vesicles uninjured during the progress, and for avoiding afterwards the premature removal of the crusts.

4. Enter all cases in your register on the day when you vaccinate them, and with all particulars required in the register up to column 9 inclusive. Enter the results on the day of inspection. Never enter any results which have not been inspected by yourself, or your legally qualified deputy. In cases of primary vaccination, register as "successful" only those cases in which the normal vaccine vesicle has been produced; in cases of re-vaccination, register as "successful" only those cases in which either vesicles, normal or modified, or papules surrounded by areolæ, have resulted. When the vaccination of an unsuccessful case is repeated, it should be entered as a fresh case in the register.

5. Endeavour to maintain in your district such a succession of cases as will enable you uniformly to vaccinate with liquid lymph directly from arm to arm; and do not, under ordinary circumstances, adopt any other method of vaccinating. To provide against emergencies, always have in reserve some stored lymph;—either *dry*, as on thickly-charged ivory points, constantly well protected from damp; or *liquid*, according to the method of Dr. Husband of Edinburgh, in fine, short, uniformly capillary (not bulbed) tubes, hermetically sealed at both extremities. Lymph, successfully preserved by either of these methods, may be used without definite restriction as to time; but with all stored lymph caution is necessary, lest in time it have become inert, or otherwise unfit for use. If, in order to vaccinate with recent liquid lymph, you convey it from case to case otherwise than in hermetically-sealed capillary tubes, do not ever let more than eight hours intervene before it is used.

6. Consider yourself strictly responsible for the quality of whatever lymph you use or furnish for vaccination. Never either use or furnish lymph which has in it any, even the slightest, admixture of blood. In storing lymph, be careful to keep separate the charges obtained from different subjects, and to affix to each set of charges the name, or the number in your register, of the subject from whom the lymph was derived. Keep such note of all supplies of lymph which you use or furnish, as will always enable you, in any case of complaint, to identify the origin of the lymph.

7. Never take lymph from cases of re-vaccination. Take lymph only from subjects who are in good health, and, as far as you can ascertain, of healthy parentage; preferring children whose families are known to you, and who have elder brothers or sisters of undoubted healthiness. Always carefully examine the subject as to any existing skin-disease, and especially as to any signs of hereditary syphilis. Take lymph only from well-characterised, uninjured vesicles. Take it (as may be done in all regular cases, on the day week after vaccination) at the stage when the vesicles are fully-formed and plump, but when there is no perceptible commencement of areolæ. Open the vesicles with scrupulous care to avoid drawing blood. Take no lymph which, as it issues from the vesicle, is not perfectly clear and transparent, or is at all thin and watery. From such a vesicle as vaccination by puncture commonly produces, do not, under ordinary circumstances, take more lymph than will suffice for the immediate vaccination of five subjects, or for the charging of seven ivory points, or for the filling of three capillary tubes; and from larger or smaller vesicles take only in like proportion to their size. Never squeeze or drain any vesicle. Be careful never to transfer blood from the subject you vaccinate to the subject from whom you take lymph.

8. Scrupulously observe in your inspections every sign which tests the efficiency and purity of your lymph. Note any case wherein the

vaccine vesicle is unduly hastened or otherwise irregular in its development, or where any undue local irritation arises; and if similar results ensue in other cases vaccinated with the same lymph, desist at once from employing it. Consider that your lymph ought to be changed, if your cases, at the usual time of inspection on the day week after vaccination, have not, as a rule, their vesicles entirely free from areolæ.

9. Keep in good condition the lancets or other instruments which you use for vaccinating, and do not use them for other surgical operations. When you vaccinate, have water and a napkin at your side, with which invariably to cleanse your instrument after one operation before proceeding to another.

*N.B.*—Supplies of lymph are furnished to medical practitioners on personal application at 3, Parliament Street, London, S.W., between the hours of 12 and 2; or by letter (unstamped) addressed to the Medical Officer of the Privy Council, 3, Parliament Street, London, S.W. (National Vaccine Establishment.)

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at a meeting of the Court of Examiners, on July 27th.

Allen, Marcus Henry, Brighton (St. Bartholomew's)  
Aylen, Thomas Vaughan, Southsea, Hants (St. Bartholomew's)  
Barrow, Henry John Walter, Woolwich (Guy's)  
Brookfield, John Storrs, Halifax, Nova Scotia (Edinburgh School)  
Cartwright, John Peelope, Oswestry, Shropshire (St. Bartholomew's)  
Davies, David Arthur, Swansea (University College)  
Elkington, Ernest Alfred, Birmingham (Birmingham School)  
Hadley, Clement, Birmingham (Birmingham School)  
Hazel, William Francis, Oakley Square, N.W. (King's College)  
Hill, Charles Hamor, Teddington (St. Bartholomew's)  
Latimer, Henry Arthur, Plymouth (Guy's)  
McDonald, Michael Sweeny, Glasgow (Hull School)  
Marley, William Lane, Padstow, Cornwall (Middlesex)  
Mayne, Thomas, Stonehouse, Devon (University College)  
Meredith, William Appleton, Wimpole Street (University College)  
Monks, Frederick Aubin, Hoxton (Guy's)  
Morgan, Edward Rice, Swansea (King's College)  
Payne, George Speke, Hartfield, Sussex (St. Bartholomew's)  
Phillips, George Arthur, Whitwell, Herts (St. Bartholomew's)  
Rees, Albert Barnes, Swansea (St. Bartholomew's)  
Saunders, Arthur Rich, Haverfordwest (University College)  
Slack, George Frederick, Montreal (Charing Cross)  
Thrupp, James Godfrey, Marylebone Road (St. George's)

Five candidates having failed to acquit themselves to the satisfaction of the Court of Examiners, were referred to their hospital studies for six months.

Admitted members on July 28th.

Adcock, Hugh, Hunstanton (Guy's)  
Benham, William Thomas, Bristol (Bristol School)  
Bland, William Charles, Notting Hill (St. Bartholomew's)  
Bodman, Francis Henry, Devizes (St. Bartholomew's)  
Chambers, John Louis, Hackney Road (London)  
Clark, Henry Edward, Glasgow (Glasgow School)  
Coleman, William Franklin, Toronto (Canadian School)  
Gibson, Charles Henry, Dublin (Edinburgh School)  
Grayson, Francis Dorrell, Henley-on-Thames (Guy's)  
Hinchcliff, Edwin, Victoria, Australia (Edinburgh School)  
King, William Louis, Great Malvern (University College)  
Lucas, Thomas Pennington, Leominster (Westminster)  
Noad, Henry Carden, Hereford Road, W. (St. George's)  
Ransom, Frederick Parlett Fisher, Elmham, Norfolk (King's College)  
Robertson, Hugh, Toronto (St. Thomas's)  
Warren, George Milton, Toronto (St. Thomas's)  
Watson, Walter George, Talbot Road, W. (St. Mary's)  
Williams, Richard, Farnham, Surrey (Glasgow School)

Five candidates having failed to acquit themselves to the satisfaction of the Court of Examiners, were referred to their hospital studies for six months.

**ROYAL COLLEGE OF SURGEONS, EDINBURGH.**—The following gentleman passed his first professional examinations during the July sittings of the examiners.

Ritchie, Thomas George Gordon, Prestonpans

The following gentlemen passed their final examinations, and were admitted Licentiates of the College.

Ferguson, Daniel, Glasgow  
Gibson, George, Dublin  
Lombe, George, St. George, co. Down  
Mahony, Philip, India  
Moore, Samuel William, London  
Parry, Lloyd Davenport, Argyle  
Sanderson, T. Drummond, Edinburgh  
Scott, William Gifford, India  
Strathy, F. R. Lee, London, Canada  
Trimble, James, Enniskillen

**ROYAL COLLEGES OF PHYSICIANS AND SURGEONS, EDINBURGH: DOUBLE QUALIFICATION.**—The following gentlemen passed their first professional examinations during the July sittings of the examiners.

Arnold, Howard, Antrim  
Baird, James, Alloa  
Chambers, Theodore Stewart, Jamaica.  
Flamstead, William, Bengal  
Goodenough, Wm. Hessman, Carlisle  
Jackson, Richard, Lancaster  
O'Hanlon, W. Palliser, Bandon, Cork  
Steedman, D. M'Kenzie, Cape Town

The following gentlemen passed their final examinations, and were admitted L.R.C.P. Edinburgh and L.R.C.S. Edinburgh.

Anderson, William, Glasgow  
Bonnar, Thomas Walker, Dunfermline  
Clarke, Arnold, Cavan  
Hindle, James, Lancaster  
Jackson, Alfred, Yorkshire  
Kane, John, Adelaide  
Keys, Robert Atchison, Strabane  
Leadman, Alexander D. H., Bradford  
M'Kay, John Hector, Nova Scotia  
Mackie, John, Roxburghshire  
Nixon, Thomas, Lincolnshire  
Oliver, William, Coleraine  
Pentland, Henry T. de M., Quebec  
Pickering, Thomas Fenna, Cheshire  
Renton, William, Knaresborough  
Rutherford, R. Acheson, co. Leitrim  
Stafford, John Francis, Wexford  
Stewart, George James, Craignish  
Todd, James John, Rathfriland  
Wallace, Samuel Lane, Londonderry  
Young, William Edward, Belfast

**APOTHECARIES' HALL.**—The following gentlemen passed their examination in the science and practice of medicine, and received their certificates to practise, on Thursday, July 27th, 1871.

Brittin, Frederic George Morris, Wansford, Northamptonshire  
Clarke, John Clelland, Coleraine, Ireland  
Hartridge, Gustavus, Yalding, Kent  
Norman, George, Stockwell Park Road, Brixton

The following gentlemen also on the same day passed their first professional examination.

Birch, Robert, King's College  
Groves, Matthias, St. Bartholomew's Hospital  
Langley, Frank, Guy's Hospital  
Maclean, Allan, St. Thomas's Hospital  
Oates, James Pimlott, General Hospital, Birmingham  
Strugnell, F. W., St. Bartholomew's Hospital  
Vennings, Edmund, University College  
Waylen, George S. A., St. Bartholomew's Hospital

**APOTHECARIES' HALL OF IRELAND.**—The following gentlemen, having passed their professional examinations, obtained the licence to practise on July 21st.

Barber, Alexander, Coleraine  
Mason, William, Dublin  
Palmer, Joseph M., Armagh  
Rice, Thomas David, Tralee

## MEDICAL VACANCIES.

The following vacancies are announced:—

BATTERSEA, Parish of—Two Medical Officers of Health.  
BOURNEMOUTH GENERAL DISPENSARY—Resident Surgeon.  
BRIXWORTH UNION, Northamptonshire—Medical Officer for District No. 2.  
DALRY IRON-WORKS, Ayrshire—Surgeon.  
EDINBURGH VETERINARY COLLEGE—Professor of Zootomy or Comparative Anatomy; Professor of Cattle Pathology.  
GREAT NORTHERN RAILWAY—Surgeon for the Grantham District.  
HEREFORD GENERAL INFIRMARY—House-Surgeon.  
HUDDERSFIELD AND UPPER AGBRIDGE INFIRMARY—Physician.  
KINGTON UNION, Herefordshire—Medical Officer for the Eardisley District.  
MIDDLESEX HOSPITAL—Physician; Assistant-Surgeon.  
PLYMOUTH INCORPORATION OF THE POOR—Medical Officer for the Northern District.  
SOUTH DUBLIN UNION—Medical Officer, etc., for the Palmerstown Dispensary District.  
SOUTH WESTERN PROVIDENT DISPENSARY—One Attending Medical Officer.  
UNIVERSITY OF DURHAM—Medical Tutor at the Newcastle-upon-Tyne College of Medicine.  
UNST, Shetland—Parochial Medical Officer and Public Vaccinator.

## MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

\*DICKSON, J. Thompson, M.A., M.B., elected Physician to the Infirmary for Epilepsy and Paralysis.  
\*MURRAY, John, M.D., appointed Assistant-Physician to the Hospital for Sick Children, Great Ormond Street, vice \*J. F. Payne, M.B., resigned.  
SYMONS, Henry, Esq., appointed Demonstrator of Practical Physiology at St. Bartholomew's Hospital Medical School.

## BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication.

### BIRTHS.

ADDENBROOKE.—On July 28th, at Kidderminster, the wife of \*E. H. Addenbrooke, Esq., of a son.  
FURNISS.—On July 26th, at Hudworth Cottage, Castle Eden, the wife of \*J. Junius Furniss, L.K.Q.C.P.I., of a son.

### DEATHS.

BANKIER, James, M.D., Staff-Surgeon R.N., at Glasgow, aged 66, on July 26th.  
GRAHAM.—On July 8th, at Embleton, Northumberland, aged 43, Eleanor Jane Isabella, wife of Robert B. Graham, Esq., Surgeon.  
GRAHAM, Robert Buchanan, Esq., Surgeon, at Embleton, Northumberland, aged 41, on July 13th.  
LOMAX, Arthur Robert, Esq., Surgeon, at Eardisley, aged 50, on July 20th.  
\*SHEPHERD, Robert, Esq., Surgeon, at Grantham, aged 54, on July 25th.  
WHITE, John, Esq., Surgeon, at Storey's Gate, aged 73, on July 28th.

## OPERATION DAYS AT THE HOSPITALS.

MONDAY	Metropolitan Free, 2 P.M.—St. Mark's, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.
TUESDAY	Guy's, 1.30 P.M.—Westminster, 2 P.M.—National Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.
WEDNESDAY	St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.
THURSDAY	St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.
FRIDAY	Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic Hospital, 2 P.M.
SATURDAY	St. Thomas's, 9.30 A.M.—St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Lock (Clinical Demonstrations and Operations), 1 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—East London Hospital for Children, 2 P.M.—Hospital for Women, 9.30 A.M.

## NOTICES TO CORRESPONDENTS.

ALL Letters and Communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen Street, Lincoln's Inn Fields, W.C.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

TO PURCHASERS.—To insure attention, it is requested that all orders sent to the Office for extra copies of the JOURNAL be accompanied with halfpenny stamps for the amount.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

MR. W. F. MORGAN'S attention is called to the announcement as to cards of membership printed in large type over the leader last week, and repeated on the face of the JOURNAL to-day.

MR. SWAIN (Devonport), DR. AVELING (London).—All names of authors intending to read papers at the annual meeting, which were received at the office up to the time of going to press last week, were duly announced in the JOURNAL. The packet containing the additional names referred to, having been delayed in the post-office in its transmission from Birmingham, was not received until Friday, when the JOURNAL was printed, and in course of distribution. The names appear this week.

THE TREATMENT OF GANGLION.—We have received a note from Dr. Pirrie, of the Aberdeen Royal Infirmary, which came too late for previous insertion in the reports from this Infirmary, in which he states that he invariably treats ganglion by forcible rupture with the thumb, and when that fails, by subcutaneous puncture and pressure with the thumb. He has never seen any untoward results, or any return under these methods of treatment.

## ANTISEPTICS AND DISINFECTANTS.

SIR,—I must beg you to allow me a small space in the JOURNAL to reply to Mr. C. Calvert's letter on my paper on disinfectants. In the first place, I must express my extreme regret that anything I said in that paper appeared to Mr. Calvert to be of a personal character, for nothing was further from my thoughts. The paper was but a fragment of a much larger one on the various uses of carbolic acid, another portion of which is now in your hands for publication, and was written at a time when I thought Mr. Calvert was in practice as a physician in London. The abruptness of the style is due to my having "cut a long tale short" at your request, and the very points which I omitted are now being arrayed against me by Dr. Sumner and Mr. Calvert.

Mr. Calvert complains that I did not discuss his experiments in a scientific form, but this is merely expressing my objections to his experiments. The substances employed, and the circumstances under which they were placed were so various, that no scientific deduction could be drawn from them. Mr. Calvert does not appear to have considered all the bearings of his experiments, for he says that if I had regarded them, I should have found that the solution of carbolic acid he employed was not strong enough to coagulate albumen, forgetting that it was the vapour of carbolic acid, and not the watery solution, that he was testing as to its antiseptic powers. His experiments consisted simply in this; he suspended a piece of meat in an atmosphere containing carbolic acid and vapour, an atmosphere containing a little carbolic acid, and several pieces in simple atmospheric air. Near these latter, it is true, some well known antiseptics and disinfectants were placed, but as they were not visible, they did not preserve the meat, and were therefore declared to be not true antiseptics.

With regard to disinfecting linen and cotton goods by boiling, I find on inquiry that in this I am confirmed by Mr. Holland, of the Burial Board, that in most laundries, and in almost all colleges, the linen is not boiled at all. The custom is to put a large mass of linen into a washing tub, and pour hot water upon it. The possibility is that even the outer layers of linen are never raised to the boiling temperature, and before the inner ones are reached the water has sunk many degrees in temperature.

I know by experience that sulphur ointment made with sulphur which has been highly impregnated with sulphurous acid, is a more powerful remedy for itch than simple sulphur ointment.

I know by experiment that a quantity of sulphurous acid which is hardly recognised by the nose or smell, and which renders brown paper but does not bleach it, is sufficient to impregnate communication, and destroy various vegetable and animal parasites.

ROBERT BAX, July 31, 1871.

(CHARLES ROBERTS, F.R.C.S.)

NOTICE TO ADVERTISERS.—Advertisements should be forwarded direct to the Printing-Office, 37, Great Queen Street, W.C., addressed to Mr. F. H. HEATHCOTE, not later than Thursday, twelve o'clock.

We have in hand at this moment a large accumulation of papers—some read at Branch meetings, and others from members of the Association who have contributed them without passing them through the Branches, and many of them quite worthy of publication. The almost simultaneous occurrence of so many annual meetings of Branches, and the forthcoming annual meeting of the Association, throw an especial strain upon the JOURNAL at this time of the year. It may be worthy of consideration, looking to the natural desire of members for the early appearance of papers read at these meetings and marked for the press, whether some modification is not desirable of the periods of annual meeting of the various Branches, so as to allow their literary products to be forwarded in sequence rather than simultaneously.

RAILWAY ARRANGEMENTS FOR THE ANNUAL MEETING.—Dr. Bryan (Northampton) writes: I have corresponded with the manager of the Great Western Railway, and have obtained the concession from him to relax so far the tourist regulations as to allow a single tourist ticket to be issued to any of our members separately on the production of his card of membership; and he has given directions accordingly. Hence, for one month from Paddington to Plymouth, the fares will be, first class, 66s.; second class, 46s. According to the printed rules, tourist tickets are only issued to parties taking two tickets—which would have shut out many persons travelling singly.

We are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The New York Medical Gazette, July 29th; The New York Medical Record, July 20th; The Boston Medical and Surgical Journal, July 20th; The Madras Mail, May 20th; The Shield, July 29th; The Philadelphia Medical Times, July 12th; The Philadelphia Medical Independent, July 15th; The Birmingham Morning News, July 28th; The Northamptonshire Herald, July 29th; The Carlisle Express and Examiner, July 29th; etc.

COMMUNICATIONS, LETTERS, ETC., have been received from:—

Dr. George Johnson, London; Mr. C. Roberts, London; Dr. Madge, London; Dr. Aitken, Edinburgh; Dr. Falconer, Bath; Dr. J. Thompson Dickson, London; Dr. Hutchinson, Scarborough; Mr. T. Watkin Williams, Birmingham; Mr. G. F. Hodgson, Brighton; Mr. Anthony Temple, Kington; Mr. T. Collier, Ripon; Dr. H. Charlton Bastian, London; Mr. Venman, London; Dr. T. Clifford Allbutt, Leeds; The Rev. Dr. Haughton, Dublin; Mr. W. F. Morgan, Bristol; Mr. G. Cowell, London; Dr. C. Kidd, London; Dr. J. Roth, Northampton; Our Berlin Correspondent; Mr. Seymour, Brighton; Dr. P. Eade, Norwich; Mr. W. P. Swain, Devonport; Dr. Angus Mackintosh, Callington; Dr. R. Lord, Crewe; The Registrar-General of England; The Secretary of Apothecaries' Hall; The Registrar-General of Ireland; Mr. T. M. Stone, London; The Registrar of the Medical Society of London; Dr. Ford, Mains Riddell, by Dumfries; Mr. Hele, Aldeburgh; Dr. Procter, York; Dr. F. J. Brown, Rochester; Dr. Underhill, Great Bridge, Tipton; Dr. J. J. Phillips, London; Mr. J. N. Stevens, Plymouth; Our Dublin Correspondent; Dr. Wade, Birmingham; Mr. J. K. Kenyon, Wroughton; Mr. J. Monteith, London; Mr. B. Armitage, Stafford; The Medical Officer of the Privy Council; Mr. R. W. Goldie, London; Dr. Ransome, Bowden, Manchester; Dr. Althaus, London; Mr. J. Sampson Gamgee, Birmingham; The Secretary of the Sydenham Society; Messrs. A. and C. Black, Edinburgh; Dr. F. T. Bond, Southampton; Mr. B. Scott, Stamford; Dr. W. Squire, London; Dr. Tilbury Fox, London; Mr. Richard Davy, London; Dr. Jameson, Aberdeen; Mr. James Lane, London; Mr. A. T. Norton, London; Dr. Bryan, Northampton; Dr. R. Barnes, London; Dr. Smart, C.B., R.N., Penge; The Medical Officer of the Privy Council; Dr. Radcliffe, London; Mr. Berkeley Hill, London; Captain Burgess, London; Dr. T. Maunsell, Dublin; Mr. Benson Baker, London; Dr. L. Sayre, Bern; Mr. W. J. Square, Plymouth; etc.

## BOOKS, ETC., RECEIVED.

A Guide to the Treatment of Diseases of the Skin: with Suggestions for their Prevention. By Thomas Hunt, F.R.C.S. Ninth Edition. London: 1871.

The Physics and Physiology of Spiritualism. By W. A. Hammond, M.D. New York: 1871.

Galvano-Therapeutics: the Physiological and the Pathological Action of the Current upon the Acoustic, Optic, and Sympathetic and Pneumogastric Nerves. By W. B. Nefel, M.D. New York: 1871.

On the Physiological Effects of Severe and Protracted Muscular Exercise; with special Reference to its Influence upon Excretion of Nitrogen. By Austin Flint, Jr., M.D. New York: 1871.

A Treatise on the Diseases of the Nervous System. By William A. Hammond, M.D. New York: 1871.

Preliminary Report and Table of the Population and Houses enumerated in England and Wales, and in the Islands in the British Seas, on 3rd April 1871.

Brain Exhaustion. By Frederick Needham, M.D. London: 1871.

St. Moritz as a Health Resort. By R. Whitfield Hewlett, M.D. London: 1871.

The Baths of Bormio. By R. Whitfield Hewlett, M.D. London: 1871.

The History of the Small-Pox Epidemic in South Shields, 1871. By Andrew Leat, M.D. Edin. South Shields: 1871.

On Bone setting (so-called), and its Relation to the Treatment of Joints Crippled by Injury, Rheumatism, Inflammation, etc. By Wharton P. Hood, M.D. London and New York: 1871.

An Experimental Research on the Antagonism between the Actions of Physostigma and Atropa. By Thomas R. Fraser, M.D. Edinburgh: 1871.

## PRESIDENT'S ADDRESS,

DELIVERED AT

THE THIRTY-NINTH ANNUAL MEETING OF THE  
BRITISH MEDICAL ASSOCIATION,*Held in PLYMOUTH, August 8th, 9th, 10th, and 11th, 1871.*

BY JOHN WHIPPLE, F.R.C.S.,

Consulting Surgeon to the South Devon and East Cornwall Hospital.

WITH an inaugural address of this description there must ever be a certain amount of difficulty in the selection of a subject. So many branches of science invariably present themselves to the mind's eye, on either of which it would be tempting to dilate, that it becomes a bewildering task, if not an invidious compromise, to discriminate between their respective claims. That dilemma, which involves the option between—what may technically be termed infringing another's patent—a presumptuous encroachment on ground already appropriated by abler occupants and cultivated by more skilful hands, and a persistent restriction to the limits of a sphere either specially or professionally one's own, at the risk of appearing conventional to some, and of really proving tedious to many more, can only be successfully evaded by the simple process of rejecting both alternatives, and by wandering away to other scenes where may be found some neutral spot unassailable by either objection. Surely no one can cavil at the soundness of that political economy which recommends emigration to a more distant locality, when the homestead is overstocked and the neighbouring district tenanted by more enterprising and better qualified competitors. Should any other apology for my selection of Plymouth as the subject of this address be deemed necessary, I shall simply rest it on personal and professional grounds. I would pay a grateful tribute alike to the town itself and to the strangers it now welcomes, by reminding them that they are now treading on historic soil, and that there are many special features of interest associated with its past history which are too often forgotten in the whirl of present sensation, or are shorn of their real value by the curious yet fashionable propensity that is so rife among us—of subordinating home scenes and English antecedents to those of a purely foreign extraction. On the other hand, professional experience abundantly testifies that the mind cannot bear too heavy a strain, or digest at once more than a fair proportion of substantial or stimulating diet. Keeping this in view, I find my course more accurately defined. It is to send you forth to the duties and details of your respective sections with your digestive faculties unwearied, and your mental grasp unimpaired by any homeopathic treatment of my own. If it be true that the science of agriculture depends much on a due application of the rotation of crops, we shall not be far wrong in adapting a similar principle to an analogous field—the human mind. In both cases the sure condition of an ultimate return is a judicious appreciation of, and a proper deference to, those elements which may not inaptly be termed the surface and hidden depths of their respective systems. As with the field so with the mind—a summer's fallow may have its advantages, and the crop of sprightly tares turn out no mean preparation for an ample yield of weightier cereals. Unlike the mushroom creations of modern days, Plymouth has a pedigree which will bear inspection. If we explore the myths and legendary lore of antiquity—those volatile but yet portentous clouds on the horizon of history which have such a hazy indefinite attraction for so many of us—we shall find that on this spot giants fought, and were vanquished in the most approved manner by champions of lesser calibre; whilst tradition even goes so far as to affirm that it is from such encounters we may trace the first germs of a characteristic presumed, with slight exceptions, to be peculiar and indigenous to the West. At all events, we can easily understand why the science of wrestling found such enthusiastic adherents in the county of Devon, when we remember that here provincial prowess scorned other and more artificial weapons than the thews and sinews of manhood in its conflicts with these doughty assailants. In such a school the mysteries of such a science could not fail to be well taught and amply illustrated, whilst any proficiency attained in it must have been intensely practical, and not likely to be forgotten.

Leaving, however, these gleanings from the region of romance, let us pass on to firmer, because less debatable, ground. In Domesday Book we have something tangible, though after all it is but a microscopic glimpse of Plymouth under the name of Sutton or South Town, when

it formed part of the royal domains. It was doubtless very small and insignificant at that time; for we learn from Leland that even in the reign of Henry II it had made but little progress. Nevertheless there were germs of vitality in the place which he termed “a mene thing as an inhabitation of Fischars”, which only needed time for development, and eventually proved to be of rapid growth. Westcote thus alludes to this epoch: “It was sometime called Sutton or South Town, and being the land of Valletort, had that adjunct, Sutton-Valletort, or Sutton-Vautour. These were but two poor fishing towns at first, and of little regard; but when the convenience of the harbour, the commodious situation, and pleasant and salubrious habitation, was vulgarly known, it enticed many to repair hither, and increased so suddenly that of two or three small villages was made, by conjunction of them, this one spacious, populous, and rich Plymouth.” Its magnificent and commodious harbour seems to have been the chief cause of its material progress; for “the first important historical fact of which we have any record as connected with the town, is the assembly there, about the year 1287, of a large fleet of ships—325 in number—under the command of the Earl of Lancaster, brother of Edward I, which sailed for Guienne”. But prosperity has its disadvantages. It provokes the reprisals from which insignificance or mediocrity are comparatively safe, and is a challenge which envy and enmity will in rare instances pass by unnoticed. Thus with Plymouth. No sooner had it become a place of mark in the history of the nation than it had to bear the brunt of national disaster. In 1339, Plymouth was unmistakably the scene of a French invasion. Nor was this a mere exceptional instance. It simply proved the forerunner of a series of attacks, some more serious than others, which occurred during the subsequent century. That they were invariably repulsed is a matter of history; but that they were attended with much suffering to the unfortunate inmates of the town, involving at one time the destruction by fire of six hundred houses, is no less notorious. And yet a critical appreciation of historic facts, however much it may deplore, cannot exactly condemn, such a catastrophe as being altogether unmerited. Looked at in the light of a retributive act, Plymouth had certain special claims to the chastisement it received. In its case there was a peculiar anomaly which could invite no other result. In the first place it was comparatively defenceless; in the second it was superlatively aggressive. Without fortifications, it was a tempting bait for hostile reprisals; and as a standing menace to the French coast, from having been the headquarters of the Black Prince in his operations against that country, it justified, if it did not necessitate, their infliction. Under such a combination of circumstances, Plymouth at that crisis in its history learned a lesson which has lately been reproduced with startling effect at Sedan. As with individuals so with nations, aggressive tendencies will often prove costly experiments, unless the science of self-defence be thoroughly mastered and minutely applied before their development. Adversity, however, unfortunately for the optimists of the present day, is very often the only school in which wisdom is acquired; and, like the burnt child which dreads the fire, Plymouth took its burning to heart. “These continual attacks of the French upon the town,” we are told, “caused it to be selected as a national point of defence when in 1442 it was decided to have upon the sea continually eight ships from Candelmas to Martinmas.” If we smile at this proof of a national idiosyncrasy, which fails to lock the stable-door until after the steed is stolen, we try to find a guarantee for present security in the reflection that to be forewarned is to be forearmed—that it is our province to keep aloof from foreign complications, not merely until we are presumed to be in a position to enforce our view of the difficulty under solution, but until, humanly speaking, we are prepared for every emergency—contingencies of evil as well as those of prosperous omen.

Passing with a brief survey that tempestuous epoch of civil strife, when the houses of York and Lancaster strove for the ascendant, let me simply remind you that here Warwick landed, and commenced that victorious march which, successful from its suddenness, won for Henry VI the kingdom for a little interval, and subsequently culminated in the irreparable disaster at Barnet; that here Margaret of Anjou on that same day of evil augury also landed, to blanch the Red Rose's lustre on the fatal field of Tewkesbury. Then we come to an eventful period in the history of Plymouth—the reign of Elizabeth. Hear Camden's testimony to its repute at that time: “The town is not very large; but its name and reputation is very great among all nations, and this not so much for the convenience of the harbour, as for the valour and worth of its inhabitants.” Very specific on this point was Carew, from whom I also quote: “Here mostly have the troops of adventurers made their rendezvous for attempting new discoveries and inhabitations; as Thomas Stukeleigh for Florida, Sir Richard Grenville for Virginia, Sir Humphry Gilbert for Newfoundland, Sir Martyn Frobisher and Master Davies for the North-west Passage, Sir Walter Raleigh for Guiana.” Thus in the field of geographical exploration *facile princeps*, Plymouth might

well rest satisfied with such associations were there not other considerations, practically of greater value, which really outvie them. If it be a far higher effort of genius to consolidate the fruits of victory than to organise a superficial and resultless triumph over hostile combinations, the pioneers of our colonial system—those men of iron will and daring hardihood who first settled in the newly-discovered continent—must ever occupy a loftier niche in the temple of fame than even those hardy adventurers who ploughed a pathway through the waste of waters to its unknown shores. It was from Plymouth, and under the auspices of Devonshire men in the reign of Elizabeth, that the first colonising expeditions set sail; and though they were not successful in the attempt to form permanent settlements, yet it is from these sources that we trace those subsequent results which have had such a marked influence on the destiny and civilisation of the whole world.

But not only in the comparatively peaceful field of adventure did Plymouth win its laurels at this era. These were portentous times—times without a doubt when British alarmists had no unsubstantial grounds for gloomy prognostications. And the thunder-crash came at last. England must be annihilated; and, with the haughty arrogance of assured victory the gigantic Armada was launched forth for its destruction. I need not dwell on the oft-told tale of ambition crushed, and the Invincible destroyed. That well-worn page in a nation's history needs no reopening here. Let me rather introduce you to a scene which, striking in itself, may, from its local associations, not be so familiar as the sterner details of history to the majority among you. In the year 1588, there was a great gathering at Plymouth. Men had not met together then as now, to wander hand in hand in peaceful rivalry over the fertile field of science. They had met for action, sharp, prompt, and decisive; and there was an unmistakably rough and ready look about them which was exactly in keeping with their purpose. If we fail to detect it here at this present moment, let us rather congratulate ourselves on an alteration of circumstances, than indulge in querulous repinings on the evidence of national decay. But the Armada was expected then, and the British Fleet was lying in Catwater. For a nation that somehow has the reputation of never being exactly ready for an emergency, it is satisfactory to remember that on this occasion a fleet was actually prepared and impatiently waiting for the expected collision. Here were assembled all those great captains of the age whose renown is imperishable. Here were Raleigh and Sheffield, Grenville and Howard, Francis Drake and John Hawkins, Martyn Frobisher, John Davis, and a host of others on the watch for earliest information with respect to the movements of the hostile armament. Somewhere about the site of the present citadel there stood in those days the "Pelican Inn," very likely so-called after Drake's famous ship wherein he circumnavigated the world. The presumption may be hazarded that it was neither so commodious nor complete in its arrangements as the Royal Western Yacht Club which you will now find on the Hoe; but be this as it may, it seems to have answered the purpose of its naval frequenters sufficiently well. Behind it was a small bowling-green, where in friendly pastime they could wile away the long, tedious hours of their protracted suspense; whilst in front of it they could command a magnificent view of the Sound, and descry the earliest approach of friend or foe on the distant horizon. And here it appears that the men on whom England relied in her hour of extreme peril were actually collected—that thus were they engaged when the long-anticipated intelligence of the Armada's approach at length arrived. How they acted in the emergency is aptly illustrated by Drake's terse rejoinder—"There is time enough to play the game out first, and thrash the Spaniards afterwards." I am aware that such-like waifs and strays from local history are often entirely lost sight of amid the more engrossing conflict of imperial interests. This is a result which cannot be sufficiently deplored. Sorely straws like these are faithful indications of a nation's temper. Without effort they mark its changes, without pretence they define its bearings. Immaterial as it may appear to many, Drake's reply is a clue to Drake's success, and the scene on the bowling green of the Pelican a solution of the Spanish disaster. Such indomitable coolness in the hour of danger more than any other characteristic has conduced to make England what it is. Less pretentious than the fiery enthusiasm which we misname valour, it is a truer courage. Alike provident and self-reliant, if it fails to obviate a reverse, it knows how to endure it; if it must experience a disaster, it is not so inconsistent as to challenge it.

That we are not wrong in anticipating that characteristics like these must leave their impress on a nation's history the sequel amply testifies. Passing on to the time of the civil war, we find the spirit of Drake still pervading the town of his adoption. All throughout those days of fratricidal strife Plymouth gave a stubborn and consistent support to the Parliamentary cause. If your Royalist proclivities are somewhat startled by this claim to reputation being seriously advanced, there is

one consideration which will considerably modify your strictures on its development. However much mankind may differ on abstract theories, there seems to be a common consent among all parties to admire persistent energy and indomitable resolution when brought to the support of cherished principles; and it is absolutely refreshing, amid the political trimming and tergiversation of a later stage, to point to that unswerving tenacity of purpose which, having adopted its line of policy, steadily pursued it under difficulties without compromising the duties it involved or evading the responsibilities it assumed. Whatever side we may take in a vexed question, we can all concur in rendering our tribute of praise to the unwavering fidelity which shrinks from no sacrifice in the support of the one it maintains. If in all cases the end to be attained does not justify the means which are used for that purpose, it is no less true that there are instances presumable wherein the prestige of the end in view is considerably enhanced by the means employed to promote it. And without a doubt Plymouth at this time may claim, even from the bitterest antagonist of the course it pursued, this spontaneous acknowledgment—that what it did it did thoroughly. Unquestionably it battled for the constitution against despotism, but it was no half-hearted allegiance that it gave to the cause it espoused. With all the earnestness that denotes a cherished conviction, it took its stand on intelligible ground; and neither by intimidation nor cajolement, by actual suffering or protracted suspense, was it induced to waver in its resolution, or constrained to shift from its position. Imbued with much of the old Puritan spirit, reverses only seemed to harden it for sterner endurance, and, trained in the school of adversity, it learned how to command, if not to deserve, success. For four long and dreary years, bearing the brunt of constant assaults, for many months closely blockaded, exposed to the severe pressure of a siege and the intermittent surprises of desultory reprisals, it nevertheless held its own, unconquered and undismayed. When Essex was vanquished, and the whole of the West overrun by the Royalists, its persistent defence was alike proof against the blandishments of the king and the valour of his troops. It neither yielded to force, nor succumbed to that deteriorating process then, as now, so insidiously contagious—a veering round as fortune changes to claim an identification of interests with the side that is successful. As it commenced, so it closed that eventful epoch—a consistent supporter of the cause it had at first embraced. And if successful, were not the elements of success inherent in it? Probably we shall not be far wrong in assuming that they were so—that they were the result of a combination of characteristics rather complimentary to the town than derogatory to its assailants.

The last historical association to which I shall but briefly refer is the connection of Plymouth with William of Orange. Still keeping up its old reputation for decision of character, it immediately declared in his favour; and here, after its leader's successful landing in Torbay, his fleet found shelter for the winter. This coincidence appears to have had considerable influence upon its subsequent destiny. It was at once an appeal to a monarch's good graces, and his introduction to a town of which he was far too sagacious not to recognise the capabilities. And so Plymouth, which since the Restoration had been assiduously engaged in commercial pursuits, began again to dabble in the arts of war. And after a time Plymouth Dock, from the impetus given to it by stormy times and belligerent propensities, expanded into Devonport; and as the enterprising daughter absorbed the purely naval elements, so its bereaved parent, burying the memory of old regrets in the fond congratulations of maternal pride, was content to become identified with the strictly mercantile interests of this great port. Thus we present the pleasing spectacle of how possible it is for national and private interests not only to have a separate and contemporaneous existence, but also to develop simultaneous progress, and cultivate reciprocal relations, without clashing and without confusion, within the confines of the same harbour. Figuratively, the wolf and the lamb are wandering promiscuously over the same pastures without detriment on the one side, or deterioration on the other. Analogously the disputed point as to whether foxes and pheasants can be co-occupants of the same preserve, finds here its solution in the affirmative.

Time will not permit me to dwell at greater length on those collateral details, without which the history of any town must necessarily be incomplete. I can neither pause to pay a passing tribute to the men of mark who have enhanced the reputation of Plymouth, nor, usurping the functions of a provincial guide, to point out to strangers the special features of interest they are likely to find here. All such matters are, however, lucidly arranged and graphically described in Worth's *History of Plymouth*,\* a book lately published by an author to whose research I myself am personally indebted for much information, and with whom you may explore pleasantly, and I doubt not profitably also, many a

\* *History of Plymouth from the Earliest Period to the Present Time.* By R. N. North. W. Brendon and Son 26, George Street.

fertile field where I have not ventured to trespass. And if you find, as doubtless you will find, that here the sword has proved more trenchant than the pen; that art also as associated with Plymouth has completely distanced literature in the race for precedence; that, in fact, with one or two notable exceptions, its literature is, comparatively speaking, a failure when contrasted with the bright array of its artistic talent, I would fain hope that your presence here may stimulate us to remedy this deficiency. Such an assemblage as the one before me must leave its mark on the future history of Plymouth, if it be instrumental in calling our attention to those shortcomings, of which we are willfully ignorant or tacitly conscious. Once recognise our defects, and a most important step has been taken towards their amelioration. That there is nothing so successful as success is a truism we cannot refute; but success, be it remembered, is never so permanent as when it is evoked from the ruins, and established upon the basis of an admitted failure. If this result be attained by your co-operation, either in awakening our emulation or in giving an impetus to latent talent, as yet crippled and confined from its never venturing to soar beyond mere local associations, or from its shunning the friction which can only give it an enduring polish, it will add the element of permanency, though not an increase of cordiality, to the welcome which I now bid you to Plymouth.

## ADDRESS IN MEDICINE,

BY

GEORGE JOHNSON, M.D., F.R.C.P.,

Professor of Medicine in King's College, London; Physician to King's College Hospital; etc.

### NATURE AND ART IN THE CURE OF DISEASE.

MANY of those whom I have now the honour to address, will remember how great an interest was excited when, about fourteen years ago, the late Sir John Forbes published his book on *Nature and Art in the Treatment of Disease*. The author of that little volume, in clear and vigorous language, with pitiless logic, characteristic truthfulness, and fearless candour, pointed out the evils resulting from what he calls the over-active perturbative treatment and the mischievous polypharmacy which were then prevalent. Sir John Forbes lamented that in his day a purely expectant treatment of disease was rarely practised, except under other colours and under other names; and he referred to the results of homœopathic treatment, which he, with reason, looked upon as simply inert, in proof of the proposition that, "the power of Nature to cure disease is infinitely greater than is generally believed by the great body of medical practitioners and by the public. So great, indeed, is this power," he goes on to remark, "and so universally operative, that it is a simple statement of facts to say, that of all diseases that are curable and cured, the vast majority are cured by Nature independently of art; and of the number of diseases that, according to our present mode of viewing things, may be fairly said to be curable by art, the far larger proportion may be justly set down as cured by Nature and art conjointly." He elsewhere remarks that cases recorded by young practitioners in the medical journals afford additional evidence of a yet stronger kind, by showing not simply the power of Nature to overcome natural disease, but to overcome this and the artificial disease superadded by what he very unpolitely calls "the energetic ignorance of the practitioner."

To the same effect, many years before, Lord Byron, when half-dead of a fever in Greece, wrote what he intended to be his own epitaph:

"Youth, Nature, and relenting Jove,  
To keep my lamp in strongly strove;  
But Romanelli was so stout,  
He beat all three, and blew it out."

After all, however, he recovered on that occasion, and he adds: "That Nature and Jove being piqued at my doubts, did, in fact, at last beat Romanelli, and here I am well, but weakly."

Since the publication of Sir John Forbes's book, and partly, no doubt, in consequence of that publication, our views as to disease and its treatment have undergone a very great change. A purely expectant treatment is now as common as then it was rare. It is now fashionable and orthodox to trust to the curative powers of Nature, and to doubt the therapeutic power of art. The pendulum has swung from one extreme to the other. At that time it was said, "that according to the vulgar notion, the function of the physician consists in little else than the prescription or administration of drugs, and the function of the patient in little else than swallowing them." Now, on the contrary,

that which was once said satirically, has come to be an almost accepted rule of practice; namely, that "the chief business of the physician is to amuse the patient while Nature performs the cure."

Now it is a very noteworthy fact that, simultaneously and side by side with this firm belief in the almost all-sufficiency of Nature and the impotence of art, there notoriously exists an extreme unwillingness to admit that any phenomena of disease can rightly be considered as having a conservative or curative tendency. The writer of an article "On the Pathology of the Microscopic Arteries," in the April number of the *British and Foreign Medico-Chirurgical Review*, had good reason for the statement which he there makes, that to speak of pathological processes as curative efforts of Nature, "is a mode of looking at the phenomena of disease always suspiciously cross-examined at the present day."

This statement suggests the inquiry whether a suspicious cross-examination is not uncalled for and out of place when the object is to arrive at truth, and not merely to gain a verdict. For the discovery and appreciation of scientific truth, the judicial impartiality of the bench is certainly more effective than the zealous and sometimes not over-scrupulous partisanship of the bar.

Surely, there is, *à priori*, good reason to believe that in the curative processes of Nature there is an orderly method of procedure, of which, by a diligent search, we may gain some useful knowledge. That marvellous reparative power which cures a fever or an inflamed lung as thoroughly as it heals a wound or mends a broken bone, must certainly work after a definite plan in each class of cases. The characteristic manner in which, during the progress of acute febrile and inflammatory diseases, the temperature rises, fluctuates, and finally falls, within a period which, for each disease, has a more or less exact limit, is one amongst other indications of such a definite plan and order. And as conservative surgery has been much advanced by a careful study of Nature's method of healing wounds and repairing injuries, so it can scarcely be doubted that a thorough analysis of the more obscure phenomena of internal diseases, and an investigation of their physiological sequence and relationship, may afford us great assistance in our endeavour to conduct our patients safely through the storm of a dangerous sickness. Indeed, I hope to carry you with me in my attempt to show that much knowledge of this kind is already available and ready for daily use.

We are all too apt to forget that disease is a natural, although an abnormal condition of the body; that pathology is, in fact, a department of physiology, and that the phenomena of disease result from the action of the normal structures and forces only modified by morbid conditions. To take an extreme case, the time, perhaps, is not far distant when we may be able to give a physiological interpretation of even that destructive deviation from the normal processes of nutrition which results in the disease recognised as cancer. Meanwhile, much aid to scientific pathology and practical medicine is to be expected from the improved teaching of physiology, to which so much attention is now being given. Unquestionably there is a great call for improved and extended physiological training; for there are manifest signs of a lamentable ignorance of the subject not only amongst otherwise highly educated laymen, but amongst medical writers who publicly discuss physiological questions, and who therefore subject themselves to public criticism. You will not have forgotten that a very influential newspaper lately endeavoured to excite the sympathy of its readers and to bring discredit upon an eminent professor, by commenting on the supposed sufferings of a decapitated frog, whose automatic movements were assumed to be the result of volition and to be indicative of pain. Then, if any one desires to test the physiological acquirements of certain writers on pathology, let him study, as I have done, the copious literature of cholera. He will find, amongst other anomalies, that one writer of great eminence considers that he has sufficiently explained the collapse of cholera when he pronounces it to be the result of "paralysis of the sympathetic nerve." Another writer on cholera having satisfied himself by experiment that the disease is communicated by the poisonous discharges from the alimentary canal, maintains that the poison does not become absorbed so as to enter the circulation, but that it has a purely local action upon the epithelial lining of the bowel.

Now the rapid absorption and diffusion of all known poisons as an essential condition of their operation is one of the best established of physiological doctrines. The interesting observations of Dr. Bence Jones demonstrated, not only the rapidity of absorption from the alimentary canal, but also the rapid diffusion of the absorbed materials out of the vessels even into the non-vascular tissues. These physiological doctrines, as well as the numerous facts which go to prove the absorption of the cholera poison, are ignored by the author of the theory to which I have referred, and if we accept his teaching we are required to believe that in the case of the cholera poison a general law of physiology is suspended.

I propose now to refer to some very obvious and well-known phenomena as examples of morbid processes having a conservative or curative tendency. Let us take, for instance, the case of a patient who is jaundiced in consequence of mechanical obstruction of the duct by a gall stone. His urine is charged with bile, the result of a vicarious excretion of bile products by the kidneys. It will scarcely be denied that the elimination of bile through the urinary channels is, on the whole, a wholesome conservative process, tending, as it does, to free the blood from impurities, the retention of which might be injurious, and even fatal. Yet, this vicarious excretion is not effected without some functional disturbance, and even temporary structural change in the kidney. An examination of bilious urine often discovers in it desquamated renal epithelium, tube casts, and sometimes albumen—pathological conditions which quickly pass away when the bile, resuming its natural course, ceases to be excreted by the kidneys.

Again, in a case of diabetes there is an abundant secretion of saccharine urine. Now, whatever may be the primary seat and essential cause of diabetes, it is certain that the free elimination of the excess of sugar by the kidneys is essentially a beneficial and life preserving process. Yet this continued secretion of sugar not unfrequently induces structural changes which ultimately lead to a fatal result. The persistent elimination of sugar by the kidneys has the effect of changing the structure and the vital properties of their secreting cells, so that, in adapting themselves, as it were, for the secretion of sugar, they gradually become unfitted for the discharge of their own proper function, namely the secretion of urine. The renal gland cells at length become opaque, and are found to contain a large amount of finely granular material with oily particles. The circulation through the kidney becomes impeded, the gland is congested, its secretion is albuminous, and suppression of urine is the immediate cause of death in a large proportion of cases of diabetes.

I believe that the familiar facts to which I have here briefly referred afford a good illustration of a principle which admits of a very extensive application to the interpretation of morbid phenomena. A large number of diseases are caused by, or at any rate associated with, some form of blood-poisoning. The morbid poisons and their products are eliminated through various excretory channels, more especially through the kidneys, the liver, the skin, the lungs, and the mucous membrane of the alimentary canal. In many instances the elimination of the morbid poison causes much functional disturbance and structural change in the excretory channels through which the poison escapes, and these structural changes constitute the most striking outward signs and diagnostic marks of the diseases with which they are associated. Thus we have the cutaneous eruptions of the acute exanthemata, the gastro-intestinal symptoms of cholera, the bowel disease of dysentery and enteric fever, the hepatic disease which results from excess of alcohol or from the influence of malarious poisons, the renal disease, which may also be caused by an excess of alcohol, by the poison of scarlet-fever, and by various other morbid poisons which I need not now stop to particularise.

Here let me say that I am perfectly well aware that by a certain class of pathologists the doctrine of the elimination of morbid poisons is ridiculed as a vestige of a by-gone unenlightened age, well enough adapted to please the fancy of old women and ill-educated laymen, but quite unworthy the acceptance of scientific physicians. One of this very advanced school lately intimated to me privately that, as a supporter of this exploded notion, he looked upon me as the priest of a decaying faith. Now it is a remarkable fact that the opponents of the doctrine in question not unfrequently render it ridiculous by misrepresenting it; the misrepresentation being, of course, unintentional and apparently an unconscious result of confusion of ideas in the minds of the critics. Thus, quite recently in one of the medical journals, an eminent provincial physician asks what we mean by the term disease, and he replies by saying,—"In old times people used to think that a disease was some actual entity or thing which had got into the body in some way and was there lying hidden and secreted, and was to be cast out. We know that there are a few instances of this kind of thing. For example, we know that some disorders depend upon the presence of a tape-worm in the intestines, and that to cure them we must hunt the worm out of the body." This idea, which we know to be true only in a few specific instances, was at one time general. The germ of this idea still runs through a great many of our conceptions of the nature of disease. This is more particularly the case in the pathological conceptions of ill-educated laymen, but many traces of it are still to be found amongst ourselves also."

I venture to suggest that the writer of the passage which I have here quoted confounds, as others equally eminent have done before, the idea of disease with that of a morbid cause. If anyone maintains, or ever did maintain, that disease is an entity having an existence apart

from the living body, I am not here to defend so manifest an absurdity. I apprehend that what we all understand by disease is an abnormal condition of the living body. The causes of disease are almost infinitely various. Some diseases have their origin in purely mental, emotional, or nervous influences, but the cause of many diseases is as certainly, if not as obviously, a separate entity as the ovum of a tape-worm. For instance, the disease which we call lead-colic is the pain with constipation experienced by a man who has been poisoned by lead. The colic, of course, can have no existence apart from the sufferer, but the metallic poison which causes the colic was introduced from without, and may be again ejected from the system. We know that small-pox and scarlet-fever can exist only as phenomena of living bodies, but the cause of each of these diseases is a material and portable poison, which, being thrown off from the bodies of the sick, conveys the disease to the healthy. The theory of contagion as generally accepted, and the practice of disinfection as commonly adopted, both imply a belief in the elimination of morbid poisons. This doctrine of the elimination of morbid poisons is, of course, quite consistent with a belief that in part they may be decomposed and destroyed within the system, although we can have no proof of the actual occurrence of this destructive process.

I almost feel that I owe you an apology for occupying your time by insisting upon such obvious elementary truths. It is strange that at a time when so much discussion is going on as to the nature of morbid poisons, when germs and dust and fungi, their nature and origin and operation upon the living body, and the best mode of preventing or neutralising their effects form the subjects of fierce controversy, there should occasionally be heard a confused utterance which seems to imply that the whole controversy is utterly impractical and unmeaning; that while a tape-worm is an undoubted fact, morbid poisons are the phantom products of a disordered brain. As an illustration of this kind of unreasonable scepticism, I may remark that a recent writer on cholera in India, Mr. Macnamara, denies the existence of a blood-poison in that disease because Dr. Thudichum failed to obtain chemical evidence of such a poison. As if Dr. Thudichum had chemical proof of the existence of any of the morbid poisons of whose reality and destructive activity the evidence, other than chemical, is only too conclusive.

And now to return to the subject of curative efforts of nature and the conservative tendency of certain morbid processes. There are few diseases which afford more striking illustrations of the principle in question than the various forms of Bright's disease when traced through all their stages from their origin to their termination. Excluding from consideration those cases of albuminuria which are caused by a mechanical impediment to the circulation, the result, usually, of cardiac or pulmonary disease, it may be held as a doctrine generally true that the primary cause of Bright's disease in all its forms is a morbid condition of blood, and that the structural changes which the kidney undergoes are the result of a conservative effort to excrete noxious materials from the circulation. In cases of transient blood-poisoning, scarlet-fever for example, the structural changes in the kidney and the functional disturbance may be only temporary and the recovery complete. But in other instances, as, for example, cases of chronic alcoholism—a very frequent exciting cause of Bright's disease—the continued passage of noxious products through the secreting structures of the kidney gradually destroys the tissues, and the gland either wastes and contracts, or becomes so structurally changed as to be unsuited for the discharge of its functions. There is then a secondary blood-contamination, a result of retained urinary excreta, and this uræmic condition may in a variety of ways bring about a fatal result. In illustration of our present subject, it may be observed that when the renal disease has reached an advanced stage life is often prolonged for a time by the vicarious elimination of urinary excreta through the mucous membrane of the alimentary canal. It is probable, too, that the dropsical symptoms which often complicate renal disease are the result of a conservative effort to free the blood from an excess of water, whose retention within the vessels would be more detrimental than its accumulation in the subcutaneous tissue and the serous cavities.

I wish to avail myself of the present opportunity to protest against a purely theoretical, although professing to be an anatomical, division of cases of Bright's disease, which originated with Virchow, and which has been accepted by some subsequent writers apparently without inquiry, and certainly without proof. A German theory appears sometimes to be as irresistible in this country as a German invasion has been found to be elsewhere. The theory to which I refer is this: That there are three forms or classes of cases of Bright's disease; in one class of cases the uriniferous tubes are the seat of structural change; in a second class the blood-vessels of the kidney are primarily and chiefly implicated; while in a third class the essential structural change consists in what is eupho-

niously called hyperplasia of the connective tissue between the tubes. Now this is a question of anatomical fact, and I am prepared at any time to demonstrate, as I have often done before—first, that in every case of Bright's disease both the uriniferous tubes and the renal blood-vessels are always structurally changed; secondly, that in no cases of Bright's disease does the essential structural change consist in a so-called hyperplasia of the connective tissue between the tubes. There is one insuperable objection to the connective tissue theory, and it is this, that the best anatomists agree in opinion that there is no connective tissue between the uriniferous tubes of a healthy kidney. It is difficult, therefore, to believe that hyperplasia or overgrowth of that which has no existence can constitute the essential anatomical character of any form of Bright's disease. Moreover, this theory compels those who adopt it to disregard very obvious structural changes within the tubes, changes which are not explained by the theory, and which are inconsistent with it.

In further illustration of conservative morbid processes, let me direct your attention for a moment to certain changes of almost constant occurrence which are found in the heart and in the minute arteries, after death from chronic Bright's disease. In the first volume of the *Guy's Hospital Reports*, Dr. Bright pointed out the fact that in a large proportion of cases of chronic Bright's disease there is considerable hypertrophy of the left ventricle of the heart, even when there is no obvious mechanical impediment to the circulation, the cardiac valves and the large arteries being free from disease. Dr. Bright, not being infected by the modern heresy which forbids us to seek for design in morbid processes, believed that this hypertrophy of the left ventricle had a physiological significance, and he suggested as a probable explanation of the phenomenon that "the altered quality of blood might so affect the minute and capillary circulation as to render greater action necessary to force the blood through the distant subdivisions of the vascular system." About four years since I had the satisfaction of being able to demonstrate as an anatomical fact, that which Dr. Bright had long before suggested as a reasonable hypothesis. I will state briefly the steps by which I was led to this result. It has been conclusively proved that the force which propels the blood through the systemic arteries is derived from the contraction of the muscular walls of the left ventricle of the heart. The force of elastic resiliency in the walls of the large arteries is derived from the muscular contraction of the heart as obviously as the elastic power of an archer's bow has its source in the muscles which bend the bow. The elastic walls of the arteries, distended by the injecting force of the ventricle, contract when that force ceases to act. The resiliency of the arterial walls, reacting upon the blood during the diastole of the ventricle, gradually converts the intermitting jet of blood from the heart into a continuous stream in the minute arteries and capillaries, just as the net-covered India-rubber ball in the ether-spray apparatus converts the intermitting current of air into a continuous stream in the tube beyond. The larger arteries have their walls mainly composed of yellow fibrous tissue, with but a small proportion of muscular fibre; on the other hand, the walls of the smallest arterioles which terminate in the capillaries are mainly composed of muscular tissue. These minute arteries, with their muscular walls, under the influence of the vaso-motor nerves, regulate the blood-supply to the various tissues and organs. By the contraction of their walls the arterial canals are narrowed, and the blood stream is in a corresponding degree lessened; on the contrary, relaxation of the arterial walls enlarges the canals, and a fuller stream of blood is permitted to pass. The minute muscular arteries, therefore, perform the function of stop-cocks; they exert a regulating, but not a propulsive, influence upon the blood stream.

Now let us proceed to apply these well established physiological doctrines in explanation of the hypertrophied left ventricle in cases of chronic Bright's Disease. It occurred to me as in the highest degree probable, that if, as Dr. Bright long ago suggested, the morbidly altered blood is impeded in its passage through the smaller blood-vessels, the cause of this impediment must be an excessive contraction of the muscular walls of the minute arteries. Then, if this were so, the continued over-action of the arterial walls should result in hypertrophy of their muscular tissue, and the degree of over-action would be found registered in the thickened arterial walls. The next step was to search for this hypertrophy of the arterial walls in cases of chronic Bright's Disease, when *post-mortem* examination showed that hypertrophy of the left ventricle existed, without disease of the valves or the large arteries to explain its occurrence. Accordingly we sought for it, and found it unmistakeably present, not only in the minute arteries of the kidney, where I had often seen it many years before, but also in those of the pia mater, the skin, the intestines, and the muscles. It will probably be found to exist in the arteries of other tissues which we have not yet examined. There is good reason to believe that the undue contraction of the arteries which results in hypertrophy of the walls is excited by

the abnormal quality of the circulating blood, while the hypertrophy of the left ventricle is a natural result of the increased action required to force the blood through the resisting arterioles.

Now it is obvious that, in order to maintain the exact balance between the propulsive force of the heart and the regulating power of the minute arteries, there must be a nice relationship between the hypertrophy of the ventricle and that of the arterial walls in each tissue. It is manifest, too, that if the arteries in any tissue are relatively less hypertrophied and strengthened than those in other parts of the system, the capillaries of that tissue must be liable to be over-distended, and even ruptured, by the injecting force of the hypertrophied heart. In accordance with this view, we found that in one case of chronic Bright's Disease, complicated with cerebral hæmorrhage, the minute arteries of the brain were certainly less hypertrophied than those of other tissues in the same subject. In another case of hæmorrhagic effusion into the retina, the arteries of the retina presented no appearance of hypertrophy, while those in other tissues were as obviously hypertrophied as were the walls of the left ventricle.

In these days of specialism, when the tendency is to dis sever the various organs of the body, and to forget their physiological relationship to each other, it is interesting and instructive to find that the deterioration of the blood which results from the degeneration of one organ—the kidney—may induce hypertrophy not only of the walls of the heart, but also of the walls of the minute arteries in every tissue throughout the system. A good illustration of this of the very ancient doctrine that, "if one member suffer, all the members suffer with it."

Time will not permit me to comment upon the various symptoms of Bright's Disease, which receive their explanation from the anatomical changes which I have described. There is, however, one phenomenon to which I must make a passing reference. A full, hard, resisting radial pulse, with increased arterial tension, as indicated by the sphygmograph, is commonly observed in cases of chronic Bright's Disease. The explanation is obvious, by reference to the two antagonistic forces, that of the strong left ventricle, and that of the equally strong, resisting arterioles. So that, when the history of a case and the chemical and microscopical characters of the urine are insufficient to determine the question whether the renal disease is chronic or of recent origin, the physical signs of hypertrophy of the left ventricle, with increased arterial tension, afford important confirmatory evidence.

Before I pass on to the next division of my subject, I wish to say another word in defence of the teleological argument as applied to the structure and functions of the living body, whether in health or in disease. It is sometimes asserted that we can learn nothing of causation, or purpose or design, and that our sole business is to study the sequence of phenomena. Yet it is notorious that some of the greatest discoveries in natural science have been made by men who have followed up, step by step, the evidences of design and purpose in the structure of organised beings. By this process of observation and reasoning, Harvey made the grand discovery of the circulation of the blood. Mr. Darwin, acknowledged even by those who differ from him to be one of the greatest and most philosophical of living naturalists, is indefatigable in his endeavour to discover and to explain the purpose and the design displayed in the structure of animals and plants. Thus, with reference to the wonderful ball-and-socket ornaments on the wing-feathers of the Argus pheasant, Mr. Darwin says: "No one, I presume, will attribute the shading, which has excited the admiration of many experienced artists, to chance—to the fortuitous concurrence of atoms of colouring matter. That these ornaments should have been formed through the selection of many successive variations, not one of which was originally intended to produce the ball-and-socket effect, seems as incredible as that one of Raphael's Madonnas should have been formed by the selection of chance daubs of paint made by a long succession of young artists, not one of whom intended at first to draw the human figure" (Darwin's *Descent of Man*, vol. ii, p. 141). He argues that those who deny that this beauty of plumage is designed to captivate the female bird, will be compelled to admit that the extraordinary attitudes assumed by the male during the act of courtship, by which the wonderful beauty of his plumage is fully displayed, are purposeless; and he adds, "this is a conclusion which I, for one, will never admit."

Now this surely is a teleological argument. Obviously then Mr. Darwin sees no inconsistency between teleological reasoning and the theory of evolution, of which he is so powerful a supporter, and so eloquent and able an exponent.

Again, the writings of John Hunter abound in the most ingenious suggestions as to the physiological purpose of morbid processes. For example, he gives a reason for the cessation of the circulation when the respiration is suspended. He says it depends upon "the sympathetic connexion which exists between the heart and lungs (one action ceasing, the other also ceases); which sympathy is established, because if

the heart were to continue acting, it would send improper blood into the body, by which it can be supported only a little while. The right auricle and ventricle also cease acting, although not so early, and for the same reason; because on the cessation of the function of the lungs, the blood cannot receive any benefit in passing through them. These actions and cessations are all dependent on life and the connexion of one action with another." (Palmer's *Hunter*, vol. iii, p. 78.)

We now know that the immediate cause of the arrest of the circulation following upon apnoea is the resistance to the passage of blood offered by the contraction of the minute pulmonary arteries, and not the cessation of the heart's contractions as Hunter supposed; but we may still believe that the final cause or purpose of the arrest is that which Hunter suggested—namely, that when respiration is suspended, nothing would be gained by sending the blood through the lungs, or by supplying the tissues with un-aërated blood.

During the time which remains to me to-day, my purpose will be to show that, as practitioners of medicine, we have something more to do than to watch the phenomena of disease as passive spectators, and that in our endeavour to prevent, to mitigate, and to cure disease, we have a better guide than mere empiricism.

Obviously, one of the most essential conditions for the successful treatment of disease is an exact diagnosis. If diseases essentially different are confounded together, it is impossible to arrive at any trustworthy conclusion as to the effect of particular remedies or plans of treatment. Nor does it suffice for successful treatment that a disease be correctly named and referred to its right place in a nosological system. I need only refer to the group of cases which are designated epilepsy to illustrate this proposition. There is reason to believe that the immediate cause of an epileptic convulsion is, in all cases, identical—namely, a sudden and extreme anæmia of the brain; but the remote and exciting causes of this cerebral anæmia are numerous and very diverse. It may be a result of failure of the general circulation consequent on profuse and rapid hæmorrhage, or a plug of fibrine (embolism or thrombosis) in the pulmonary artery; or the pulmonary, and consequently the systemic, circulation may be rapidly arrested by one of the various forms of apnoea; or by the accidental admission of atmospheric air into the veins during the performance of a surgical operation at the root of the neck or in the axilla. But in most cases of epileptic convulsion the arrest of the circulation and the cerebral anæmia are probably due to a sudden and extreme contraction of the minute intracranial arteries. The exciting causes of this arterial contraction are very various. It may be the result of a purely nervous or reflex influence acting, through the vaso-motor nerves, upon the cerebral vessels. Examples of this form of epileptic convulsion are afforded by cases in which the determining cause is emotional excitement or mental anxiety, syphilitic or tuberculous inflammation of the brain or its membranes, painful dentition, the irritation of intestinal worms. In another class of cases, blood-poisoning is the immediate cause of the arterial contraction. To this group belong cases of uræmic convulsions—convulsions the result of alcoholism, and the convulsions which sometimes occur during the initiatory fever of the acute exanthemata. If the treatment of epileptic convulsions is to be successful, or even harmless, we must do something more than give the disease a name and prescribe bromide of potassium, valuable as that remedy is in many cases of this terrible disease.

We are sometimes told that our chief duty as practitioners is to treat symptoms, and to leave pathological theories to those who have nothing better to occupy their time and attention. A patient consults us for aphonia; shall we prescribe for this symptom without looking into the larynx to ascertain its cause? Loss of voice, more or less complete, may be a result of a transient functional nervous derangement; it may be caused by the pressure of an aneurism, or of a cancerous or other tumour, upon the pneumogastric nerve or its recurrent branch; it may be a direct result of a simple or a malignant tumour within the larynx, or of the swelling or ulceration which results from the various forms of inflammation to which the larynx is liable. For the practical purposes of prognosis and treatment, it is not sufficient to be able to say of a disease that it is laryngitis; we have farther to ascertain to which of the three large groups of cases it belongs; namely, the catarrhal, the strumous, or the syphilitic form of laryngitis.

Again, when it is said that we are to treat symptoms, is it meant that we are to make it a rule of practice to endeavour to repress all the symptoms of disease without reference to their origin, their physiological significance, or their probable conservative tendency? Such a rule would lead to the repression of the eruption of scarlet-fever and small-pox by external cold, to the abrupt arrest of choleric discharges by opium, and to the weakening of a strongly pulsating hypertrophied heart associated with valvular disease by low diet and depletion—modes

of treatment condemned alike by pathological science and by the results of experience.

In estimating the results of treatment, the ultimate appeal must obviously be to experience; experience, however, has notoriously proved, in many instances, a fallacious guide—*experientia fallax* is a maxim which we shall all do well to keep continually in mind.

But, of all the delusive guides in practice, a false theory of disease is the most to be dreaded. It was an erroneous theory that suggested the antiphlogistic treatment of delirium tremens and the narcotic and alcoholic treatment of cholera; and theory alone prevented the more speedy discovery and rectification of these practical errors.

A knowledge of the causes of disease, and of their *modus operandi* in the production of morbid phenomena, may be made practically useful in many and various ways. The evidence obtained within the last few years of the manner in which cholera and enteric fever spread through the contamination of the air and drinking-water by the intestinal discharges, has greatly increased our power of preventing these destructive diseases. The ascertained influence of comparative dryness of soil and of atmosphere, resulting from improved drainage, in diminishing the mortality from phthisis in various parts of America and in this country, forms another important contribution to practical and preventive medicine.

To discover, and if possible to remove, the exciting cause, may sometimes suffice for the cure of a disease of most formidable nature and of obscure pathology. In illustration of this statement, I am tempted to relate very briefly the following case. A boy suffering from tetanus came under my care in the hospital. The symptoms, which had existed for rather more than a week, had commenced about ten days after the infliction of a wound in the upper part of the thigh by a sharp piece of wood. The wound had healed; but I found that the cicatrix was remarkably hard and tender when pressed. While examining the case, I remembered two fatal cases of traumatic tetanus referred to by Dr. Taylor in his book on *Poisons*. In both cases, the wound had healed; but in one there was found after death, beneath the cicatrix, a piece of iron; and in the other a splinter of wood. Thinking it not unlikely that some foreign body might be present in my case, I gave the boy chloroform, and requested the house-surgeon, Mr. Whitmore, to cut through the cicatrix. In doing so, he found neither iron nor wood beneath the skin, but a piece of woollen stuff of about the size of a small pea. The stick which wounded the boy's thigh had pierced his cloth trousers, and, carrying with it a piece of wool, had left it in the wound. The tetanic symptoms gradually subsided. Repeated small doses of chloral apparently assisted the recovery; but, if the foreign body had remained under the skin, it is probable that neither this nor any other remedy would have prevented a fatal result.

There is a numerous and important class of cases in which suppressed action of the skin by cold or by some unknown atmospheric influence is the exciting cause of disease in internal organs: for example, cases of acute renal dropsy, whether occurring during the progress of scarlet fever, or unconnected with that disease; cases of catarrh and bronchitis; cases of acute pneumonia; and some cases of acute rheumatism. Now there is a principle of practice common to all these cases, which is this: that if, at the very commencement of the disease, a free action of the skin can be promoted, the malady may often be cut short; or, if not entirely and promptly arrested, it will be greatly mitigated. It is notorious that an ordinary catarrh may almost certainly be cured by free diaphoresis at the very commencement of the attack. I have myself gone into a hot-air bath suffering from headache, pain in the limbs, and other indications of a severe incipient catarrh, which, if allowed to run its course, would probably continue for a period of from one to two or three weeks; and in the course of half an hour the symptoms have been entirely removed by the action of the bath. The same treatment by hot-air or blanket baths is certainly very efficacious in the early stages of acute renal dropsy, more especially when cold has been the exciting cause of the disease. The object of the diaphoretic treatment in these cases is not, as some writers appear to imagine, to sweat-urine through the skin, but, by diverting a large amount of blood to the surface, to lessen the congestion of the kidney—as dry cupping over the loins does in a less degree—and thus to increase the secretion of urine. The objection which has been made to this sweating practice—that it tends to waste a portion of the water which is required to wash morbid products from the uriniferous tubes—affords a good illustration of the insufficiency of mere physics to explain physiological phenomena.

In connexion with this diaphoretic practice, I have a few words to say on the treatment of catarrhal pneumonia. With reference to the treatment of pneumonia, two very distinct stages of the disease must be distinctly recognised—first, a febrile prepneumonic stage; second, the stage of pneumonic exudation. The commencement of an attack which

results in pneumonia is usually marked by rigors, a high temperature, quickness of pulse and breathing, not unfrequently vomiting or diarrhoea, or both. Then follow the signs of exudation into the lung; and as a rule, in an uncomplicated case, when the lung-tissue is consolidated, the temperature quickly falls, and the pulse and respiration become less frequent. Then, more or less rapidly, the inflammatory exudation is expectorated, and the lung is restored to its normal condition. I maintain that pathologically there is an analogy between the pulmonary exudation of pneumonia and the cutaneous eruption of small-pox, in so far as the initiatory fever abates when the exudation occurs—in the one case into the lung, in the other into the skin. Both are febrile and eruptive diseases; in one disease the eruption being pulmonary, and in the other cutaneous. Now I believe that, by treatment promptly applied during the febrile pre-pneumonic stage, the amount of subsequent exudation may be greatly lessened. The treatment suggested by theory and approved by experience consists in the prompt restoration of the suppressed cutaneous secretion, by hot air or water or wet sheet and blanket baths, an emetic of antimony or ipecacuanha when there is nausea without vomiting, and a calomel and colocynth pill, followed by a saline purgative. I have no doubt that by these means, adopted at the very commencement of the febrile stage, the severity of the disease may be very much mitigated; whereas, after the pulmonary exudation has occurred, the time for active treatment has passed: rest and food are then the chief requisites. To discuss the treatment of pneumonia without reference to the stage of the disease, is to include, under one name, pathological conditions essentially unlike.

It remains for me now to sum up in a few sentences the main points which I have had the privilege to bring before you.

I have suggested that a belief in the power of Nature to cure all curable diseases is inconsistent with a disbelief in the existence of morbid processes having a conservative or curative tendency. I have indicated various pathological phenomena the conservative tendency of which appears to me indisputable; and I have endeavoured to show that, by a careful study of the functional and structural changes which result from disease, we may obtain most valuable indications for treatment—learning thereby both to do that which may aid Nature and to avoid such means as may tend to thwart and hinder the natural curative processes.

Again, I have intimated that it is difficult, and, as it seems to me, impossible, to reconcile a disbelief in the elimination of morbid poisons with a belief in the spread of disease by contagion. Confirmatory evidence as to the elimination of morbid poisons is afforded by the disastrous results of repressive methods of treatment. To take all possible precautions to exclude the cholera-poison from the system, and then, when once it has gained an entrance, to endeavour to retain it there by opiates and astringents, are practical modes of procedure utterly inconsistent with each other; unless, indeed, the object of this repressive treatment be to sacrifice the individual for the public good—to prevent the patient, at the peril of his own life, from scattering the seeds of disease and death amongst the community.

I believe that the success of our attempts to cure and to prevent disease depends mainly upon an exact diagnosis and discrimination of the various forms and shades and stages of disease; upon a correct interpretation of pathological processes and symptoms; a careful avoidance of erroneous and misleading theories; and, lastly, upon a prompt recognition of the exciting causes of disease, some of which may be avoided, some removed, while the influence of others may be in a greater or less degree counteracted by the timely employment of suitable means.

#### THE USE OF IRON IN SCARLATINA.

I AM desirous of drawing the attention of the profession to the use of iron in scarlatina. I have given it for the past two years with great success; so much so, as to induce me to believe that in it we have a powerful remedial agent for that disease. I have found, if it be given as soon as the disease makes its appearance, that not only does it shorten and lessen the severity of the attack, but it also fortifies the patient against the after-consequences—dropsy, etc. The form which I have mostly used has been the liquor of pernitrate of iron, in syrup or glycerine, in doses of ten minims every three hours for children of from one to six years, increasing, according to age, to fifteen, twenty-five, or thirty minims. During convalescence, I have given citrate of iron and quinine, ammonio-citrate of iron, or syrup of phosphate of iron, according to circumstances. This, with the exception of warm fomentations to the neck in cases of scarlatina anginosa, is all the treatment I have adopted, and, as I have before stated, with better result than has followed any other. I hope soon to give cases; but in the meantime I ask my professional brethren to give my suggestion a fair trial, and I believe they will be well satisfied with the results.

RUSSELL ALDRIDGE, M.D.

## CHOLERA:

ITS DIFFUSION, PROPHYLAXIS, SYMPTOMS, AND TREATMENT.\*

By JOHN MURRAY, M.D.,

Inspector-General of Hospitals, Indian Medical Service.

As cholera is regularly advancing from India through Russia and the Baltic ports towards England, and as the disease has pursued this course on several previous occasions, its arrival here may be shortly anticipated. As August and September are the months during which the last three epidemics prevailed in England, it is now time for every precaution to be taken to guard against its attack. As I have had opportunities of seeing this disease in India every year since 1833, I have been requested to relate the results of my experience in that country; and I willingly do so in the hope that it may be useful.

It is important that information should be given regarding the early symptoms of cholera and its treatment, as a delay of two or three hours will in many instances allow the disease to advance to a stage where those remedies will prove powerless, which, if exhibited sooner, would have controlled the disease and saved the life of the patient.

Much of the difficulty in understanding cholera has arisen from writers only acknowledging the presence of the disease when it has reached the third stage or collapse. I beg to state that the opinions to which I shall call attention on most of the important points in this disease are supported by a very great majority of the medical officers now in India, as shown in a recent report submitted by me to the Indian Government, in which the opinions of 505 medical officers are carefully tabulated.

In no malady are there more marked and characteristic symptoms than in cholera; but the symptoms, which are only found in one stage, are so dissimilar to those induced by the poison in an earlier stage or mild attack, that the connection has by many been overlooked. The value and importance of the early detection of the presence of the poison cannot be over-estimated, as we all know that, after a certain stage, the vital organs are rendered, by the absent or diminished absorption of the stomach, little sensible to the action of remedies; their functions are paralysed by the presence of the poison. It is in preventing the supervention of this stage that most life has been saved; and the physician who can soonest detect the presence of the poison will be most successful in his practice.

The earliest symptoms that can be recognised are those of *malaise*, viz., depression of spirits, want of appetite, torpidity of the bowels, and desire for stimulants. That the *malaise* I have described is caused by the presence of the poison of cholera is an opinion strengthened by the fact that, during an epidemic attack, when this feeling exists, the action of a purgative—especially salts—will almost always be followed by the other symptoms of cholera, and the circumstance of the frequent occurrence in men who have left the infected locality in apparent health and have been attacked within one or two days.

To the symptoms of *malaise* succeed *diarrhoea*, nausea, and vomiting; the urine is scanty; the stools light-coloured, then colourless, like rice-water, with occasional cramps, heart-burn, and slight headache. The countenance is dark and the eye-balls congested. This is followed by *collapse*, great prostration of strength, burning in the epigastrium, congee or rice-water vomiting and purging, with cramps and suppression of urine; cold clammy perspiration, feeble pulse and cold breath, broken voice and shrunk and livid face. When reaction takes place, the burning pain in the epigastrium disappears, the restlessness subsides, the stools become coloured, urine is secreted, warmth returns to the palms of the hands, the colour improves, the pulse becomes stronger, and sleep ensues.

In many instances the disease does not progress beyond the stage of *malaise* or *diarrhoea*. The poison appears to be digested or eliminated by the *vis medicatrix nature* through the natural functions of the system—hence the great importance of supporting these, and avoiding their being overtaxed, exhausted, or depressed.

Cholera is a specific disease, caused by the presence of a specific poison in the system; it multiplies or is reproduced; it must be vital and amenable to the ordinary laws which regulate other specific poisons, modified by the peculiar structures of the body which are chiefly affected. It must enter the body through some of the ordinary channels. Before health can be restored, it must be eliminated either in a vital state or after being decomposed or digested. Although we are unable, in many instances, to trace the manner in which the poison enters the system,

\* Read in the Medical Section at the Annual Meeting of the British Medical Association in Plymouth, August 1871.

yet in others the channel is evident and the source clear. The instances where cholera has appeared after drinking water contaminated by cholera discharges from wells, streams, tanks, or vessels, are numerous and well authenticated. The most convincing case which has come under my own notice occurred during the Hurdwar epidemic of 1867, when a pilgrim arrived at Jough Kullian in the Punjab, on the 28th April. He was taken ill with cholera near a well and died next day. He had bathed, and his soiled clothes were washed in an adjoining pond. Other parties who afterwards visited the well and the pond for water and abluion were attacked two days afterwards; and up to the 15th May, fifty-three were attacked in that village, of whom twenty-seven died. There had been no cholera there for the previous twenty-four years.

I have witnessed numerous cases and heard of many more where the poison must have entered through the lungs; those attacked having been in the vicinity of cholera patients, or of their evacuations. It is difficult to show that the skin is the channel of communication, because the poison may be disseminated in the surrounding air, and thus enter by the lungs. But there are many instances on record of the disease appearing after the wearing of clothes worn by cholera patients; and Dr. MacLean mentions that the last case that occurred in the attack at Malta in 1865, was that of a washerwoman who stole a soiled shirt and wore it.

The poison leaves the body through the same channels by which it enters; viz., the bowels, the lungs, and the skin. Its presence in the discharges from these organs is recognisable in most instances by the smell—a mawkish, sickening odour, well known to those who have seen much of the disease. In the earlier stages the poison appears to be destroyed, or digested, without exciting any active symptoms, and this is the safest way of nature getting rid of it. The first active symptom is diarrhoea; and here we can be useful, as the system during this stage is amenable to remedies.

I shall now allude to some facts that are important in a practical point of view, as tending to promote or restrain the diffusion of the disease. I carefully examined the Records in the Medical Department in Calcutta from the year 1814, and found that, with the exception of the Delta of the Ganges, where the disease is never absent, its appearance in an epidemic form is limited to certain seasons and extending over three months in the year, and that this period of the year varies in different parallels of longitude; but there were sharp occasional attacks at other seasons.

The period of observation in Europe is shorter. It is probable that the disease may have appeared in former ages under the general names of plague, black death, or sweating sickness; but all the ordinary symptoms of what are called sporadic cases have frequently been found. The epidemics of 1849, 1854, and 1866, occurred in August and September; and we may infer that the arrival of the disease which is now gradually advancing therefore will be at the same season, and it becomes our duty to prepare for its advent.

All experience of the course of the disease teaches us that it rages with the greatest intensity, and proves most fatal where people are collected in great numbers—where there is crowding and filth, defective ventilation and impure water; and that it is aggravated by want and bad food. It is here that the circumstances of civilisation bear on the propagation of the disease.

Great benefit has arisen from a careful attention to the laws of sanitation, which have been assiduously studied of late years by many zealous investigators of this branch of medical science. Sanitation is of the greatest importance in the precautionary treatment of this epidemic, in ameliorating the violence of the attack, restraining its dissemination, or warding it off entirely. On sanitation there is no difference of opinion; and both the medical profession and the public are aware of its importance, and its direction is in good hands.

There is another point of no less importance in the precautionary treatment, on which the profession was not in former years so unanimous. I allude to the contagious nature of the disease, meaning thereby the transmissibility, directly or indirectly, of the specific poison from a sick to a healthy person. I am unable to state the exact proportion of those who consider cholera as non-communicable in Europe or America; but in India there were only five out of five hundred and five medical officers who stated that it is not communicable. There is a slight divergence of opinion regarding the channel through which the communication takes place, and the changes undergone by the poison after leaving the diseased person, but none as to a diseased person being a source of danger if admitted into a healthy locality. The precautionary measures indicated by this opinion consist in the exclusion and isolation of the affected, and the removal of the healthy from the infected locality.

There has been a great diminution of mortality from epidemic cholera in India, particularly amongst the European troops, and in the garrisons, since precautionary measures founded on these indications have been

carried out. In many cases, cantonments and prisons have remained free from attack whilst the disease has raged amongst the population of the surrounding districts, and the mortality has been materially diminished in most of the stations where it did break out; still, in several stations and garrisons where the sanitary arrangements have been carried out by most efficient officers, there have been very severe and fatal outbreaks of the disease under my own superintendence, particularly in the cantonments of Peshawar, Kohat, Allahabad, and Gwalior, and in the Central Prison at Agra, which has long been celebrated for the completeness of its sanitary arrangements.

There was great difficulty in carrying out measures for its exclusion even from the garrisons and cantonments; and it is questionable if they were ever strictly observed in large towns. In England the disease must enter by the sea-ports; and the admission of ships with the disease on board is more under control, and should be restricted, and the cases treated on board special cholera hospital-ships. I question the possibility of perfect isolation of any hospital on land, unless it be an island. When the disease has once appeared in a port or town, special cholera hospitals should be established, with which there should be no unnecessary communication. Small detached buildings, tents or huts, are best for cholera cases: the air is purer, and the depression from the sight of the suffering and death of other patients is diminished.

The removal of troops or prisoners is a simple process in India. The supply of tents and means of carriage is ample, and the surrounding country open. In small villages the inhabitants desert their homes and live in the open air; and many who have the means leave the large towns. The precautionary arrangements in towns have been limited to the construction of special cholera hospitals and the general distribution of medicines. People have generally a great aversion to leaving their homes and entering a cholera hospital; but these hospitals were generally filled with travellers and poor people. Restrictions were occasionally attempted in infected localities in the towns, but it is questionable if they did any good. The free use of disinfectants applied to the evacuations has been employed with marked advantage.

In thus prominently calling attention to the communicable nature of cholera, I do not wish it to be inferred that I think it as communicable as many other diseases, or that there is very great danger in attending on the sick, especially in Great Britain, where decomposition is comparatively less rapid than in India. I have attended thousands of cases, and only contracted the disease three times, which yielded readily to early treatment. The exemption of hospital attendants, where prompt treatment is available, is remarkable; and the number of relatives and friends who attend in private houses and escape, or only have very slight indisposition, is generally observed. This should encourage all to neglect no duty to suffering humanity, while at the same time all unnecessary exposure should be avoided and every means used to prevent the disease being disseminated to others.

I now come to the most important branch of the subject—the medical treatment, in which the practice has been most uncertain in late epidemics, whilst some are of opinion that it is of little or no use in the advanced stages. This latter statement is not correct, and has a most injurious tendency by depressing the spirits of the patient and destroying his confidence in the physician. This confidence is a most powerful means of supporting hope when life is wavering in the balance. I have seen a patient's life hang on the expression of my face when, in deep collapse, his pulse was imperceptible at the wrist.

My object in giving in detail the symptoms of this well known disease is to enable the early presence of the poison in the system to be recognised, as it is here that medical treatment is most efficacious. It is of little importance that analogous symptoms may be induced by other causes if remedies used be not injurious to health, and they check the further development of this disease, which in an advanced stage is almost beyond the control of medicine. It is our duty to assist Nature and to relieve pain. In the stage of *malaise* the poison is thrown off without any violent or very prominent symptoms by the natural functions of the system. Our task here is to support the strength, avoid indigestible food and depressing causes. The only medicine that I have found useful in this stage is a little quinine every day. The subsequent indications of the treatment are to remove the abnormal symptoms as they appear, of which the most early is *diarrhoea*. The first indication is to check this and restore the case to the stage of *malaise*, then remove the cause and restore the natural secretions. Irritating or indigestible food in the bowels is the most frequent cause of diarrhoea; and should this not previously have been discharged in the evacuations it should be removed and a recurrence of the looseness guarded against, as I have always found it the most powerful exciting cause of collapse. I have found this best carried out by a combination of opium with carminatives in the form of a cholera pill, composed of one grain of opium, two of black pepper, and three of assafoetida. It appears to check the

looseness and stimulate the secretions. This pill does no harm if needlessly administered. It should be repeated should the looseness continue. It will cure most cases, and in all restrain the symptoms until regular medical advice can be procured. This is a most important point in the use of this simple remedy. It may be distributed to every house and be available in a few minutes, whereas the delay of a few hours may allow the disease to advance beyond control. I know no better remedy for this stage. These pills have been distributed in tens of thousands in the towns and villages of India with most satisfactory results. Some surgeons prefer red to black pepper, and others add camphor to the opium and assafoetida, and report favourably of the combination. They are distributed in the dispensaries, and are placed in the charge of the police in India. In this country, similar arrangements might be made.

In collapse, our power is limited by the circumstance that the vital organs are insensible to the ordinary action of medicines. Experience shows that opium, astringents, and alcohol, lie inert in the collapsed stomach, though these are the ordinary remedies for pain, looseness, and debility. It is also my experience that the free use of these remedies at this stage causes death, either by preventing reaction, or by causing local complications should reaction appear.

There is another cause of death which is not generally understood, but which it is in the power of all sufferers or attendants on the sick to check or to prevent. I allude to the extreme danger of assuming the erect posture, or even of sitting up in bed, during collapse, or the earlier stage of reaction. I have seen myself, and I have heard of many cases, where fatal syncope instantly followed sitting up in bed or rising to go to stool.

It must be borne in mind, while indicating the treatment in this stage, that the poison of the disease is contained in the congee evacuations in an active form, and also that the first sign of reaction is coincident with the appearance of bile in the evacuations. The dilution of the irritating contents of the bowels and the restoration of the watery particles of the blood are indicated and best fulfilled by frequent small quantities of cold water, to which a little soda or carbonate of ammonia may be added with advantage. In protracted cases I have seen decided benefit from the use of Liebig's extract of meat, made fresh and given frequently. I have also seen most marked benefit from the exhibition of hot saline enemata given after each motion. In some instances it has acted like magic, the symptoms subsiding after one injection, but in many others they have been powerless. I have thought that the artificial supply of Nature's own remedies in the stage of *malaise*, the secretion of which is suspended by the action of the poison as the disease advances to collapse, might be useful, and the results in a few cases in which they were used previous to my departure for India were highly satisfactory; seven out of nine having recovered, and the two fatal cases having been pulseless and dying before the remedies were used: these remedies were gastric juice and bile, in the form of acidulated pepsine, fifteen grains, and inspissated bile fifteen grains, given alternately every hour. The first dose of bile was followed by vomiting; but bile soon appeared in the evacuations, and mild reaction set in gradually. Shampooing with warm turpentine liniments gives relief to the cramps, and mustard poultices on the epigastrium restrain the vomiting. I think I have used a little quinine with advantage when Nature made an effort at reaction.

I have only time to allude to some of the other remedies which have been highly recommended. I found bleeding unsuccessful in 1833, and I have seen no reason to change my opinion. The practice is generally condemned in India. Calomel I have found inert in collapse, both in large and small doses, and consider that the benefit attributed by many to its use arises from its being employed instead of spirits or strong remedies. There is danger of its being accumulated in large quantities when reaction takes place. Sulphuric acid and acetic acid are less dangerous; but I have not seen decided benefit from their use. I have not found advantage from ammonia, except when added in small quantities to the cold water. I found, in 1833, the transfusion of saline fluids into the veins caused most hopeful reaction; but it was only temporary, and this is the general result of numerous trials made by other medical officers in India. Brandy I consider dangerous in proportion to the quantity given in the stage of collapse, and opium as decidedly poisonous in this stage. Chloroform, though it may give temporary relief, tends to induce dangerous head symptoms on reaction. Astringents are not beneficial. Purgatives are dangerous in the earlier stages, and not useful in collapse; they are generally condemned in India. Heat has been extensively tried by warm baths, but the fatigue entailed is dangerous. It has been tried in the form of hot-air baths, but the result has not been encouraging.

When reaction takes place, rest and careful nursing will complete the cure where collapse has not lasted long; but in protracted cases,

in addition to these remedies, medical treatment may be required for low fever, uræmia, or local complications, regulated by the ordinary rules.

One of the inducements which have led me to write this paper is the hope that the confidence in the treatment of cholera, particularly in its earlier stages, which my long experience has given to me, may be imparted to others through this National Association; and be extended to the people of this country, and help to ward off panic when the disease appears amongst us. I also wish to condemn the use of violent remedies in cases that appear to be hopeless, knowing the dangers they induce, and to recommend the milder expectant treatment which has in many instances been followed by favourable results.

#### REPORT OF THE COMMITTEE ON THE OBSERVATION AND REGISTRATION OF DISEASE.

THE following report was read at the annual meeting of the British Medical Association at Plymouth, August 1871.

The past year has been full of promise of the ultimate success of the efforts of this Association to bring about a national registration of disease. At the general meeting, held at Newcastle-on-Tyne, on August 12th, 1870, it was resolved—"That a deputation from the Association should seek an interview with the President of the Poor-law Board, to represent to him the views of the Association with respect to the registration of disease, and that Dr. Rumsey, Dr. Sibson, Dr. A. P. Stewart, Dr. Morgan, and Dr. Ransome be requested to form the deputation."

In accordance with this resolution, the above named gentlemen waited upon Mr. Goschen, in conjunction with a deputation on the same subject from the Poor-law Medical Association, and several other gentlemen interested in the question. After a careful inquiry into the views of the deputation, Mr. Goschen said that the arguments in favour of the registration of disease were very clear and strong, and that every one must accept them. The chief points to be considered were by what machinery it could be carried out, how rapidly, and at what cost. He thought, however, that the question was one for the Government, and not for his department, and he remarked that it would be undesirable to go into the matter until the report of the Royal Sanitary Commission had been considered by the Government.

The report of this Commission appeared in the spring of the present year, and contained very important and conclusive arguments for a registration of disease, apparently in every respect identical with that proposed by this Association. We append an extract from this report, from which it will be seen that the Commissioners were fully impressed with the importance of the subject, and with the necessity both of obtaining speedy returns of new cases of diseases occurring amongst large bodies of the population, and of making these returns immediately available for the suppression of epidemic disease. It does not appear, however, from the recommendation of the Commission, that any definite plan for obtaining these objects is put forth, nor any arrangement made for transmitting the records through a local officer of health. Your Committee recommend, therefore, that a memorial be addressed to Her Majesty's Government, praying that in any measure of sanitary reform this most valuable aid to the suppression of disease should be fully provided for, and that arrangements should be made by which health officers could make immediate use of the returns of disease before they are transmitted to the central offices of the Government.

Your Committee regret that they have to announce the discontinuance of the returns made for the last four years by the Northumberland and Durham Medical Society. Although those made at Manchester and Salford, St. Marylebone, and Birmingham still continue, the fact that this influential body is unable to carry on the undertaking is only another proof of the need of a truly national registration of sickness.

But, however complete the registration of deaths may be, it cannot give a fair estimate of the grief and poverty occasioned by sicknesses that are not fatal; it cannot indicate where or how these are to be prevented or remedied; it cannot tell the cost which is worth incurring for their diminution. To these ends, the first step must be a registration, so far as may be practicable, of all the cases of the most prevalent and injurious sicknesses among such portions of the population as may suffice for an estimate of the general state of the public health, and especially of the health of the working classes, and of those for whom sanitary arrangements are most urgently needed.

All the witnesses examined by us on the point have spoken strongly of the need of this registration of sickness. Among the chief purposes it would serve are these:—  
1. It would keep the public, and especially the Central Sanitary Authority, constantly aware of the state of the public health in every part of the country. A certain amount of knowledge of this kind is obtained from the registers of deaths, and it would be hard to over-estimate the good service they have done; but the greatest knowledge they can supply is, not only scanty, in comparison with what is wanted and can be had, but is often too late to be useful. In nearly all cases of epidemic and contagious diseases time is lost before the deaths, few in comparison with the cases, begin to attract attention. In many instances weeks have elapsed,

before the existence of widely prevalent and preventable diseases has become known to any efficient Sanitary Authority. Thus, the best opportunities have been lost both of ascertaining the origin of epidemics, and of preventing or limiting their spread. The chances of suppressing an outbreak of disease are in direct proportion to the speed with which it becomes known to a Sanitary Authority; and it is only by a systematic registration of all cases, whether fatal or not, that the speediest information can be attained. The advantage of obtaining such information has been proved in Ireland, where the medical officers of districts, in which epidemic or infectious diseases appear, are bound to report them to the Poor Law Commissioners in Dublin, who at once send down inspectors and, if necessary, assistant medical officers.

2. The registration of sickness would teach more than we can yet guess of the magnitude of the grief and poverty caused by disease. This is very incompletely shown by a register of deaths. For example, in an epidemic of scarlet fever, the deaths are rarely more, and often less, than ten per cent. of the cases. But, reckoned by its money cost, a non-fatal case may be more costly than a fatal one; for, in the one, the cost ends with burial, in the other it has to be borne through the whole period of sickness, and of the often tedious convalescence. Moreover, after every epidemic of scarlet fever, whether it has been very fatal or not, thousands are left disabled for long periods, or for life, with diseases of the ears, or bones, or joints, the glands, or other parts; and the great majority of these are a burden on the working power of the healthy.

What is thus true of scarlet fever is equally true of other epidemics. Their mortality is no sufficient measure of the importance, whether for the sake of humanity or of economy, of preventing or limiting them. In an epidemic of relapsing fever not more than one or two of every hundred cases may appear on the register of deaths; but the cost of the other ninety-eight in every hundred must be enormous, seeing that every one of them has to be expensively maintained for many days or weeks.

Moreover, it has often been observed that an epidemic, even when very fatal, does not add largely, if at all, to the total mortality of a few years. When many die of one epidemic, fewer die of others, or of all other forms of disease. But there is no such counterbalance for the cases of sickness and disability that are left as the residue of an epidemic. These are costly so long as they continue; they are a dead loss.

Terrible as epidemics are, when we count the thousands that have died quickly in them, and guess at the misery consequent on the deaths of those who worked for others, they would seem much more terrible, if we could count the consequences of the necessity of maintaining the many more thousands, who are disabled for months or years from working either for themselves or for others.

3. It is probable that the registration of sickness would show more urgent need than is yet felt for diminishing, if possible, many diseases that, being neither epidemic nor often fatal, are commonly regarded without concern. Ague is very rarely fatal, it counts for little on a register of deaths, yet ague in all its various forms, and its long abiding, is a great hinderer of work, a great burden on the wealth of the nation, a burden which good sanitary arrangements could remove, and probably would remove if it were shown to be worth the cost.

And so of scrofula, of rheumatism and bronchitis, and of many other disabling maladies. We cannot doubt that a registration of sickness would show that not only the personal misery, but the public loss caused by these diseases is enormous. Thousands suffer either constantly or through a large portion of the year. Many of them suffer and are thus disabled year after year, and during all their sufferings they are maintained wholly or in part by the labours of others. It is probable that, on the whole, these diseases are much more costly than the most terrible epidemics; certainly they are so, if we reckon their influence on the progeny of those who suffer. And yet to what amount they are costly, or what cost ought to be incurred for their diminution, we can scarcely guess without a registration of sickness.

4. Another class of cases, of which the death registers do not nearly indicate the importance as affecting the working power of the country, are those of diarrhoea, influenza, and other widely prevalent maladies which, though often trivial to the individual, are very impoverishing in their effects on the people generally. The deaths caused by them are not felt as causes of poverty, for they are fatal to very few except children and invalids and old persons; they are often too few to attract any attention, and every year thousands suffer and are unobserved by any Sanitary Authority. Yet the cost of these diseases in loss of work is so great that it can scarcely be estimated.

5. The registration of sickness would further show whether and in what degree legislation is needed for the prevention of diseases dependent on occupations and social habits. Much has already been done in this direction, by the inquiries directed by the medical officers of the Privy Council, but the effects of many occupations on health are still unknown.

The effects of social vices and vicious habits of life, whether any of them are sources of such sickness, poverty and decay, as to justify on public grounds a considerable expenditure of money and of executive force, cannot be known without registration.

6. In all these, and in many other instances, a registration of sickness would supply a comparatively full knowledge of the prevalence and magnitude of diseases which are imperfectly indicated in the register of deaths, but of which a fuller knowledge might be expected to touch the means of prevention. Equally it would correct some errors which are scarcely avoidable in deductions from the death registers. In these, for instance, each death is registered at the place at which it occurs, whether the fatal disease commenced there or elsewhere. Yet it is obvious that, for the prevention of disease, we ought to know where it began, rather than where it ended. The registration of sickness would tell the former; that of death tells the latter.

The errors from which are not trivial. Large classes of persons, including domestic servants and "boarders on premises," usually leave the places in which they reside as soon as they feel severely ill. The places in which they die are thus made to appear more unhealthy, and those which they leave less unhealthy, than they truly are.

7. Finally, the insane, and many other persons who have been long invalided with various diseases, when they die, and this is registered as the cause of death. Yet that which it was most important to prevent, because it cost the more costly, and wasted, though it did not cause distress, life, was the earlier and longer disease which would have appeared in a register of sickness, but takes a subordinate, if any, place in a register of deaths.

8. A registration of sickness is essential as a test of the fitness of institutions for the reception of the sick and poor. The registration of deaths in various hospitals and asylums is important; yet it may tell little more than the proportions of cases of every disease fittingly admitted into them. That which ought to be known is the number and character of the cases of sickness that begin in each hospital, e.g., of fevers, of consumption, of springing up among the inmates for other ailments.

And it may be hoped that a registration of sickness would bring to light not only truly infectious and contagious, or venereal, or various phases and among various classes, but some instances from the study of which means of improving the public health might be derived. There is reason to believe, for instance, that workers in brass are

insusceptible of cholera, that people bred in rural districts are less liable, than those who live in towns, to the blood-infections following injuries. And, if these are facts, it is not likely that they are the only facts of the kind; there must be many more, which a registration of sickness would help to detect.

On all these grounds we recommend that authority and sufficient means should be given to the Registrar-General for a registration of sicknesses, under the direction of the Central Sanitary Authority. But questions may arise as to how far the registration should be carried.

It would be unwise to attempt to register all cases of sickness in the whole population. The number of cases severe enough to disable from work, or to require medical help, is probably in England and Wales not less than thirteen millions a year. The cost of registering so vast a number of facts, however simply, would be far beyond its value.

It would be impossible to register all cases in private houses. The diseases constantly registered should be those which affect large numbers of the population, which may be considered as, in a greater or less degree, preventable by sanitary arrangements, and which are usually not difficult of discrimination. The registration of other diseases than these should be by a single entry of the total number of "other diseases;" but an exact registration of any of them might be from time to time directed by the Central Sanitary Authority.

The registration would, in the first instance, include only or scarcely more than those among whom sickness is, for various reasons, already registered. These would be sufficiently numerous for a general and speedy estimate of the prevalence, in every part of the country, of the diseases which are the greatest causes of misery and the most likely to be prevented by due care. They would include all the sick attended under the poor law; the inmates of nearly all charitable institutions; patients at hospitals, asylums, and dispensaries; the workmen in some mines, factories, and other large establishments in which great numbers of persons are under the care of medical men who are obliged to make returns of all the sick they treat.

In all these cases some sort of record is made of sicknesses; but, however useful the records may be for private or local purposes, they are useless for any general or national purpose, being without uniformity, and therefore unfit for either summary or comparison. In many instances these local records include more particulars than would be necessary for a general registration; such as the name of the disease in every case, the name, residence, occupation, &c. of the patient. Details of this kind would be usefully preserved for local purposes; but the general purposes of the registration of sicknesses would be sufficiently served by a central registration of only the few most important facts, and by the Central Sanitary Authority and his officers having access to all local registers.

The method of registration may be safely left to the department of the Registrar-General. The subject has already been carefully considered in his office; and a member of his staff, Mr. James Lewis, has shown that returns for such a registration as suggested may be collected from all parts of England and Wales, and arranged and published weekly, so as to be at once accessible to both the Central and Local Authorities.

The practicability of such a registration is proved by its having been carried out by the medical authorities in the army, and by private exertions in Newcastle-on-Tyne, in Manchester and Salford, and, for a time, by the London medical officers of health. The system maintained, for the registration of the contagious diseases of animals, in the veterinary department of the Privy Council, a registration, not only of the first occurrence, but of the progress of every case, may be taken for a model of that which, it may be hoped, will some day be maintained for the registration of preventable diseases among men.

If the registration of sickness be added to the work of the Registrar-General's Office, it will make the relations of that office to the public health so much larger than to any other subjects, that it would be advisable that the office should be a department under the proposed Central Sanitary Authority.

## DRAFT REPORT OF THE PARLIAMENTARY BILLS COMMITTEE OF THE BRITISH MEDICAL ASSOCIATION.

YOUR Committee have to report that, owing to an oversight of the Committee of Council, they were not duly constituted in accordance with the resolution of the annual meeting until the greater part of the parliamentary session had passed. Prior to this, however, the Metropolitan Counties Branch had endeavoured to partly fill the blank by nominating its Parliamentary Bills Committee as formerly. Thus most of the measures introduced into Parliament affecting public sanitary questions or the interests of the medical profession, have in some form received consideration from officers of the Association.

Energetic opposition was made, through the intervention of Mr. Ernest Hart, to clauses in the Coroner's Bill threatening to deprive Poor-law medical officers and others of their fees for *post mortem* examinations conducted for inquests. That Bill was withdrawn. The Committee had great pleasure in warmly seconding Sir Dominic Corrigan's amendments to the Lunacy Regulation Bill (Ireland), and preventing the imposition on the Poor-law surgeons of Ireland of onerous duties without fee or reward. They warmly approve of Sir Dominic Corrigan's Lunacy Bill introduced this session, proposing to afford just remuneration to the Irish Poor-law medical officers for certifying dangerous lunatics, and for improving the superannuation of the medical officers of Poor-law medical asylums. This measure will be reintroduced early next session; and your Committee propose in concert with its author, to give it their warmest support, with whom they are in cordial communication. They have likewise thought it right to give their support to the principle of the measure introduced by Mr. Donald Dalrymple, M.P., for the Restraint of Habitual Drunkards; and Mr. Dalrymple attended a meeting of the Committee, and explained the

scope and provisions of his Bill; and your Committee was represented at the deputation which waited on Mr. Bruce, and elicited the promise of a Select Committee early next session to consider the whole subject.

Your Committee have also supported the appeal for the consideration of measures intended to lessen the present destruction of infant life, and especially the regulation of Baby-farming. The subject was referred to a Select Committee, whose deliberations were much influenced by the disclosures made in the *BRITISH MEDICAL JOURNAL* three years since, and the remedies then suggested. Among the most important evidence taken was that of three members of the Select Committee—Mr. Ernest Hart (the editor of the *JOURNAL*), Mr. Curgenven, and Mr. Benson Baker; and your Committee rejoice to add that the report of the Select Committee generally concurs in their views and adopts their suggestions. It is believed that the Government will introduce a measure based upon these recommendations early next session.

The amelioration of the condition and the improvement of the system of the Poor-law Medical Service have largely engaged the attention of your Committee. They supported Mr. W. H. Smith's motion, which had at least the effect of bringing on an interesting debate, and obtaining an important declaration from the Government of their intention to consider the propriety of introducing considerable reform or amendments. Mr. F. S. Corrance, M.P., has attended a meeting of your Committee, and has expressed his intention of introducing, on the first opportunity, a measure for the purpose of applying to England some parts of the Irish Poor-law medical system. He was accompanied by Dr. Rogers, the President of the Poor-law Medical Officers' Association. That Association seconds Mr. Corrance's intentions; and your Committee, after consideration of the scheme advocated, believe that it will be beneficial, and propose to support it at the proper time.

The larger questions of Poor-law Medical Reform, and of Medical Reform properly so called, as well as of State Medicine, belong to separate Committees of the Association, and have not, therefore, been dealt with by this Committee.

Mr. Stansfeld's Bill for consolidation of the public departments of Medical Relief, Poor Relief, and Public Health, came under consideration. Some objections were urged from quarters deserving respect. Your Committee, however, felt it their duty to support the measure as one of immediate and obvious advantage.

The Pharmacy Acts Amendment Bill and the Licensing Bill came under consideration on two occasions. Both have subsequently been withdrawn; but your Committee made some representations to Government as to necessary amendments, which were promised due consideration, and which will be repeated, if necessary, should those measures be revived.

As to the Vaccination Acts Amendment Bill, the Committee objected to the principle that any one should be allowed to purchase immunity from the operation of the Act by payment of a small monetary fine. They rejoice to find that the Bill proposes to authorise district medical officers to vaccinate those liable to take small-pox in houses where the disease is present, and to make payment to them as though they were public vaccinators. This clause was pressed upon the Government prior to the passing of the Bill by a deputation of the Poor-law Committee of the Association, acting in conjunction with a deputation of the Poor-law Medical Officers' Association.

Thus the session has afforded ample scope for the activity, and evidence of the usefulness, of this Committee of your Association. There is no other body possessing a similar representative character charged with the duty of watching over legislative measures affecting public sanitary interests and the interests of all classes of the medical profession. Your Committee, recognising the importance and responsibility of the task, will continue, if reappointed, to perform the duty with care and diligence. They wish to impress upon the associates at large, and upon members of the profession generally, the importance of freely communicating with them upon all measures introduced into the legislature affecting individual or collective professional interests.

#### DRAFT REPORT OF THE POOR-LAW COMMITTEE OF THE BRITISH MEDICAL ASSOCIATION.

YOUR Committee have to report that, having been convened at the request of the Chairman of the Poor-law Medical Officers' Association, they have met the Council of the Association in conference on two occasions, and have made representations to Ministers which have not been without effect.

On October 14th, they met to consider a scheme of reorganisation of the Poor-law Medical Service which had been carefully considered by Dr. Rumsey, Dr. Ransome, and other authorities, bearing partly upon this general question, and partly upon the question of Registra-

tion of Disease. This memorandum they presented, through a numerous and influential deputation, to Mr. Goschen, then President of the Poor-law Board. Dr. Sibson, Dr. Farr, Dr. Ransome, Dr. Morgan of Manchester, Dr. Phillipson of Newcastle, Dr. Stewart, and other influential members of the Association, expressed their views. The result of the deputation is reported at length in the *BRITISH MEDICAL JOURNAL*, October 22nd, 1879. It was highly favourable to the general views of the Association, and promises substantial results.

On a second occasion, your Committee met the Committee of the Poor-law Medical Officers' Association in conference on the subject of the Vaccination Regulations, and had a lengthened interview with Mr. Simon, Medical Officer of the Privy Council. The special subjects discussed were the consolidation of vaccine statements, the regulations as to gratuities, and the desirability of relaxing the rigid rules as to stationary vaccination. The deputation was received with great courtesy by the Medical Officer of the Privy Council, who discussed with them in detail the points at issue. As results of this deputation, they may point to the clause in the Vaccination Amendment Act authorising district medical officers to vaccinate in houses where small-pox is present, and to claim payment for the same. The medical officer also announced his intention of codifying and publishing the regulations concerning gratuities to public vaccinators.

Your Committee regret that they have not been constituted and called together in a more regular manner. They believe that it will be to the advantage of the profession that they should be reconstituted, in order that the Association may continue to lend its powerful aid to the officers of the Poor-law Medical Service.

They regard with satisfaction the present organisation of the English and Irish Poor-law medical officers, and trust that the Association will continue to assist with all its influence the efforts of those Associations to elevate the status of the service and increase its public usefulness.

ERNEST HART.

## REPORTS

OF

### MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS OF GREAT BRITAIN.

#### ST. BARTHOLOMEW'S HOSPITAL.

##### CASE OF HYDATID TUMOUR OF THE LIVER, WITH ICTERUS.

(Under the care of Dr. DUCKWORTH.)

THE notes of this case were kindly supplied by Mr. G. Bagot Ferguson.

Emma R., aged 25, married five years, was admitted on May 1st, 1871. She had one miscarriage three years ago. She was born in, and had always lived in, London. She could lie without discomfort in any position. The face was considerably jaundiced, as also was the body generally, the chest being most deeply stained. The jaundice commenced about four months previously, increasing, with intermissions, up to the time of admission. The ocular conjunctivae were deeply stained. The lips were dry; the tongue clean and moist, fissured longitudinally. There was no oedema of the feet and legs. Her liver was palpably much enlarged, the right lobe reaching within about three inches of the crest of the ilium in the mesial line to about two inches above the umbilicus; the left lobe reaching far into the left hypochondrium, and about four inches below the cartilages. The upper limit of the liver was normal. The abdomen over the liver was tense; and, on percussion, the so-called hydatid fremitus was evident, chiefly over the enlarged left lobe. The abdominal tension was greatest, and the prominence most marked, in the mesial line, about two inches below the ensiform cartilage. A rounded mass at the lower right border might possibly have been the distended gall-bladder. Her girth in the widest circumference was thirty-two inches. There was no ascites, and no enlarged abdominal veins were visible. The appetite was fair; no thirst; bowels open. The urine was extremely dark in colour; it had been thus only a few days. The catamenia were regular and normal. She complained of pain at the seat of the tumour, and a cramping sensation and feeling of weight. She slept badly, and suffered much from nightmare. The tumour had increased mostly during the last three or four years; but she thought it was there, though small, as long as seven or eight years ago, because of uncomfortable sensations of weight in its present site, and from the great tendency which she had to nightmare. Its growth had been attended by no actual pain. At a place where she lived as housemaid six years ago, three dogs were kept, which she petted much; she did not know if they had worms.

May 14th. She was tapped by Mr. Holden with a Thompson's

trocar, slightly beneath the ensiform cartilage, through the linea alba; and less than half a pint of light yellow slightly turbid fluid was drawn off. Microscopic examination revealed hooklets in the fluid, and granular debris of hydatid cysts, of specific gravity 1009. Trace of albumen and abundant chlorides were found. She suffered little from the operation, or afterwards, but felt relieved by it. Next day, the jaundice was less.

May 19th. She was tapped again by Mr. Holden, with a similar trocar, about an inch to the left of the linea alba. Nothing escaped, the trocar having been plugged by two cysts somewhat larger in size than a pea, lifeless and degenerating. She experienced afterwards and during the night a good deal of pain diffused over the abdomen, but was better next day. She had been put under the influence of opium.

May 24th. She was feeling very well. The jaundice was considerably less; girth thirty-one inches.

June 2nd. She was tapped again by the aspirator between and below the punctures, and about four ounces or more of fluid removed; it contained fragments of membranes, and a few shrunken and bile-stained hydatids, of specific gravity 1009. She suffered severe pain for about half an hour, and experienced some pain even next day. The girth was reduced to thirty inches.

June 10th. The girth was thirty-one inches. The urine was now natural, but became darker lately for one day.

June 12th. She was discharged at her own urgent request, and ordered to be an out-patient, and to be readmitted again at some subsequent date. She is still somewhat jaundiced.

REMARKS BY DR. DUCKWORTH.—The occurrence of jaundice with a hydatid tumour is a much more rare occurrence than might reasonably be expected. In fact, the absence of this symptom is generally a point in the diagnosis of hepatic tumours due to hydatids. In this case, although the enlargement had existed for a long time, certainly four years, and possibly more, the jaundice only came on about four months before admission. It is also noted that it has increased, with intermissions, up to the present time. When this symptom first appeared, there were no indications of rupture of the cyst into a branch of the gall-ducts; nor was there any history of biliary colic, such as would certainly have supervened had some of the secondary cysts entered the common bile-duct. The tumour did not suppurate; for no pus was found in the fluid withdrawn from it at any time, and no constitutional signs of such an event occurred. There was a slight bilious tinge in the liquid, however; and, although it could hardly be supposed that the tumour communicated directly with the biliary ducts, yet products of hepatic secretion had found access to the cysts, and may have had a share in promoting their degeneration, which was certainly in progress. It is, therefore, fair to presume in this case that, with the increase in the growth of the tumour, or of a portion occupying, or rather implicating, the lobes quadratus specially, the common duct had become much obstructed. There were no signs of catarrhal icterus; and the probable enlargement of the gall-bladder, the absence of distended abdominal veins and of ascites, would show that the ducts in the fissure of the liver were not particularly implicated.

## UNIVERSITY COLLEGE HOSPITAL.

### SKIN DEPARTMENT.

#### SEBORRHOEA SICCA VEL SQUAMOSA.

(Under the care of Dr. TILBURY FOX.)

SEBORRHOEA, or sebacous flux, is not generally recognised by medical practitioners, but is confounded mostly with eczema. In some instances, the altered sebaceous secretion may be of an oily character; in others, hard and even cornuous; and in some, again, it may form small plates or scales on the surface. The latter form of disease was well exemplified in a case which has come under Dr. Fox's care. The patient was a young woman aged 17, who, having been fat and flabby, was otherwise in good health. Two or three years previously, she had been in King's College Hospital with some lung-disease; otherwise she had never been ill. There was nothing of importance to note as regarded her family history. The disease had attacked both sides of the face—indeed, its whole surface, save the lower part of the nose and around the mouth; and had existed in a state similar to the present for the last four months. It commenced as a little red spot on the right cheek; this went away in a few days, and then the whole face became hot, red, and scaly; and in a week both sides became affected. The earliest appearance of the disease was like that of a burn. There was no "discharge" at first, and there had been none since; the surface had not been even moist, but only dry and hot. On admission, the whole of both cheeks were covered by small flat plates of the size of a split pea, very much

like those of ichthyosis squamosa; and they were stuck rather firmly in the face, but could be detached readily. They then showed a dry and red surface beneath, and a patency and prominence of the sebaceous follicles. The face had not been so freely covered until recently, because the girl always washed away the scales each day, but had allowed them to accumulate of late. She had always noticed that the scales were more rapidly and freely produced after exposing the face to the sun. The same condition of things as that just described existed on the top of the head. The glands on the neck were enlarged.

REMARKS.—No mistake ought in such a case to occur in the diagnosis. The negative evidence was strongly against the idea of the disease being eczema. It was clear that there was no discharge. The scales were fatty. The glands of the skin were seen to be enlarged, congested, and patent. On placing some of the scales under the microscope, they were seen to be made up of roundish well formed cells, and a large amount of fatty matter, mostly granular, intermingled with oily particles. There was no "blastema" or other evidence of true "inflammatory action". The treatment in the present case consisted of saline aperients at first, followed by the mineral acids, lotions of carbonate of soda and borax, and subsequently *huile de cade* ointment, with cod-liver oil internally.

## UNIVERSITY HOSPITAL, BERLIN.

### CASES FROM THE SURGICAL CLINIC.

Under the care of Dr. B. VON LANGENBECK.

(Reported by Mr. R. W. PARKER.)

I. HYDRONEPHROSIS.—A child named Hiller was brought to the hospital on May 12th, with a left single hare-lip. There was also fissure of the hard palate and velum. The child had a large abdomen, but otherwise appeared healthy. It was operated on by Professor von Langenbeck the day after its birth, and in six days the wound was quite healed. Meanwhile the child seemed to have great difficulty in swallowing, which rather increased than diminished. The child grew weaker, and finally died on the eighteenth day.

Post Mortem Examination, May 30th.—The cleft had healed, and the wound cicatrised. On opening the abdomen, the whole track of intestines was normal, but empty and contracted. The liver and spleen were healthy. On removing these organs, there remained in the abdomen an irregular mass of thin-walled intercommunicating cysts of various sizes; on dissection, they were found to be in connexion with the kidneys. The left kidney had become converted into a thin-walled fluctuating bladder, six centimètres long by four centimètres broad. From the hilus there passed an ureter as large as the small intestine, and, after many unusual windings and convolutions, entered the bladder in the normal position and manner, having resumed its usual size about three centimètres before its insertion. It was found, however, that there was a stricture of the ureter, so that the urine had difficulty in entering the bladder. On cutting into this kidney, it was found to consist of a very much enlarged pelvis, into which opened the enlarged calices. The whole was surrounded by a thin layer of gland-substance three or four millimètres thick. On the right side, in the normal position for the kidney, near the spine, nothing was found. The right kidney was situated much more anteriorly; it was converted into a mass of convoluted cysts, with thin fibrous walls, without any trace of gland-substance. From the hilus proceeded the ureter, which at its commencement was of the size of a child's stomach; it gradually narrowed, and, after much unusual winding, was inserted into the bladder. But in the bladder was found a septum dividing it unequally; and within this shut-off portion of the bladder was found the orifice of the right ureter. There was no communication with the rest of the bladder; so that the accumulation of the urine in the bladder and ureter will account for their distended condition, as also for the condition of the right kidney. From the absence of any very special symptoms, this condition of things was not in any way suspected during the infant's life. The brain and eyes were normal.

II. SPINA BIFIDA: ABSENCE OF CEREBELLUM.—The child (a girl) at the time of its birth had a soft small swelling immediately below the occiput. It was not brought to the hospital until four weeks later, at which time the swelling was of the size of a large walnut. The child, with the exception of slight hydrocephalus, was healthy and well proportioned. No active treatment was advised; but the mother was cautioned to protect the tumour from blows, and as much as possible from friction. Eight weeks later, the tumour had grown very rapidly and was as large as an ostrich's egg; the skin was tense, thin, semi-transparent, and inflamed (more especially on the under surface, wher

the tumour rested on the neck); and the superficial veins were congested. As rupture seemed imminent, it was now tapped with an exploring trocar, and about four ounces of a thin straw-coloured serous fluid were drawn off, after which the cannula was withdrawn, and the wound closed with adhesive plaster and collodion. In spite of this, however, the fluid continued slowly to ooze out, and the tumour became daily less, as also did the head. The operation produced no special effect on the child at the time; but three days later it became restless, and was seized with convulsions. It died on the fourth or fifth day.

*Post Mortem Examination.*—The spine, cord, and membranes, from the sacrum to the fifth cervical vertebra, were normal and healthy. There was neither infiltration nor congestion, and no trace of inflammation. The arches of the upper five cervical vertebrae were not closed, there being a median fissure about one *centimètre* wide; the laminae terminated in button-like processes. The covering of the tumour was found to consist of—1, integument; 2, dura mater; 3, a serous, gelatiniform, infiltrated areolar tissue; 4, a thin fine vascular membrane—a prolongation of the pia mater. The cyst contained a coagulated fibrinous straw-coloured mass. The fissure led into the central canal of the cord itself; this canal was enlarged to the extent of one-half or three-quarters of a *centimètre*. The anterior pillars of the cord were of normal size; the posterior, on the contrary, were distended and thinned to about one *millimètre* in thickness. The calvarium was abnormally large. The posterior fossa of the base of the skull was very flat. The posterior half of the foramen magnum, instead of being semi-circular, was directed backwards to a sharp angle, forming a triangle with a somewhat rounded base—as though the foramen had also partaken of this arrest in development. The tentorium cerebelli was absent, and the transverse sinus present only as far as the pars petrosa, where it terminated in a kind of *cul-de-sac*. The cerebellum was entirely absent. The pons Varolii was normal, as were also the crura cerebri. The nerves were in full number. The tuber cinereum was very thin. The third ventricle was filled with serous fluid.

III. SARCOMA OF SUPERIOR MAXILLARY BONE: EXCISION.—A man named Kilpin, aged 28, was operated on in March 1870, by Professor von Langenbeck, for a tumour in the right canine fossa, which extended also to the alveolar process. The tumour was dissected off from the jaw, and a triangular piece of the alveolar process was removed by bone-forceps. He did very well, and served as a soldier during the last war.

He had the first symptoms of recurrence during January of this year, while bivouacking out in the cold in France. He had pain in the old cicatrix, and remarked a swelling in the same place. Shortly afterwards a swelling appeared also in the right half of the hard palate. He got his discharge from the army, and was taken into the hospital. On closer examination, a swelling of the size of a walnut was found in the canine fossa. The right nostril was closed, and the right eye was also a little displaced upwards. On the hard palate there was a rounded hard swelling, accurately bounded by the median line; it was not ulcerated. On May 24th, Dr. Langenbeck removed the whole of the superior maxillary bone, including the anterior half of the floor of the orbit. In the course of the operation, it was found that the bone was very hard. The antrum was enlarged, and filled with the tumour. The floor of the orbit was pushed upwards, and perforated in two places. The external wound all healed by first intention in about six days. The man is entirely free from pain now, and doing very well. On cutting into the tumour, it was found to be of a white opaque colour. Under the microscope, it was found to belong to the fibro-nucleated tumours, consisting of closely interlacing bundles of long spindle-shaped cells, with large oval nuclei, but no stroma.

Professor Langenbeck's incision for excision of the jaw commences at a point corresponding with the junction of the nasal and frontal bones, and is carried obliquely downwards and outwards as low as the angle of the mouth (which is not touched), then upwards and outwards to a point corresponding to the centre of the zygomatic process; thus making a broad round-ended oval flap, which is dissected upwards, so as to expose the whole of the bone to be excised.

I am indebted to my friend Dr. Busch, Senior Assistant-Surgeon at the Royal Klinikum, for much help and kindness in getting these notes.

## REVIEWS AND NOTICES.

PUERPERAL TEMPERATURES AND TEMPERATURE. VARIATIONS IN THE DISEASES OF CHILDREN. By W. SQUIRE, L.R.C.P. London: J. and A. Churchill, 1871.

No one in this country has devoted more attention to the subject of temperature in the diseases of children than Mr. SQUIRE; and credit is

especially due to him from the fact that all his observations have been made, and that accurately, while engaged in a busy practice. He has shown that family practitioners have no lack of opportunities, if they choose, to avail themselves of the thermometer as a valuable clinical aid, and furthermore to collect a mass of information regarding temperature in disease, which is not so easily gathered in hospital practice. The first of the two pamphlets which Mr. Squire has just issued, that on puerperal temperatures, is devoted chiefly to the natural history of ordinary labours, in which the following conclusions are drawn by the author: "That some elevation of temperature arises in natural labour; that there is afterwards a considerable fall of temperature which is favoured by sleep; that there is a subsequent exaltation of temperature which has for its natural termination the secretion of milk." It is also shown that the diet in childbed should not be of a toast-and-water character, but that substantial alcoholic beverages may be in some cases advantageously added to substantial food. Some remarks on the use of chloroform and chloral, which are worthy of attention, conclude the pamphlet. In noticing the work on *Temperature Variations in the Diseases of Children*, we would observe that some of the results given come from carefully investigating the stage of invasion in certain diseases; thus, the period of the actual beginning of measles can be recognised and fixed so as to enable timely separation to be effected: in the same way, the early stages of whooping-cough and diphtheria. The diagrams show at a glance how measles may be said, as a disease, to end with the eruption, while scarlet fever is only beginning with it. In speaking of varicella, a diagram is given in which it is shown that the day preceding the rash the temperature is even below normal, the true beginning, in fact, of the disease; while in small-pox there is always two days' illness, and fever often as high as 105 deg. before the spots appear. Moreover, the tendency to high temperature in varicella is seen to be on the second day; and, though it may then run higher than in the case given, it has been known to be 104 deg. at its highest; and mumps has been higher still, at its acme also on the second or third day; yet it soon subsides and becomes normal by the sixth day, when no more spots appear. The incubation periods and times of infection of these complaints are considered. In treating of the value of temperature observations in diagnosis, it is shown that the temperature variation of infants follows the same rules, and is within the same limits, as that of adults, and therefore becomes as serviceable for purposes of diagnosis. Mr. Squire alludes to the low range of temperature in some children, which is, he believes, explained by a dislike to, or deprivation of fatty food. A rather singular confirmation of this has been recently afforded by the fact, that the low temperature found by Dr. Finlayson amongst the children at the Manchester Workhouse was precisely at the time when Dr. E. Smith was compelled to call attention to the insufficiency of the diet-table. Space has no more than allowed us to touch on the valuable and interesting contents of Mr. Squire's pamphlets. We confidently recommend their careful perusal and study.

## REPORTS AND ANALYSES

IN

### MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

#### STEAM-SPRAY INHALER FOR SMOKE OR VAPOUR.

MESSRS. KROHNE AND SESEMAN, surgical instrument makers to the London Hospital, have just adapted, at Mr. Bird's suggestion, the principle of his inhaling-pipe for smoke or vapour to Dr. Siegle's patent steam-spray inhaler, of which they are the proprietors. This inhaler has proved eminently successful for the employment by inhalation of medicated artificial sprays in the treatment of various diseases of the throat, nose, larynx, bronchi, etc., to which all liquid substances in the form of spray were applicable. By combining the principle of Mr. Bird's inhaling-pipe for smoke or vapour, the products of combustion, and diluting them by the steam-jet instead of air, as in Mr. Bird's ingenious little instrument, the most valuable results are obtained. The smoke of opium, stramonium, hemlock, pellitory, tobacco, lettuce, or any kind of pectoral herbs, either alone or in combination, as well as the fumes of sulphur, nitre, iodine, or mercurial preparations that require combustion to volatilise them, may be inhaled with the greatest comfort and facility by the most debilitated or nervous persons; while the temperature and the dilution by the steam-jet is so complete, as to render even the most acrid smoke or vapour perfectly respirable and most soothing and agreeable.

THE Subscriptions to the Association for the year 1871 became due in advance on January 1st. All which are not already paid, should be forwarded to the General Secretary, Mr. T. Watkin Williams, 13, New Hall Street, Birmingham; or to the Secretaries of Branches.

## BRITISH MEDICAL JOURNAL.

SATURDAY, AUGUST 12TH, 1871.

### THE ANNUAL MEETING, 1871.

THE meeting of the Association during the present week was anticipated with great interest by a very large number of members, and for varied reasons. The *locale* of the meeting promised largely that holiday element which is an inseparable characteristic of such peripatetic annual gatherings, whether brought together in the name of medicine, of science, of sociology, or of archæological research. The programme indicated discussions of great importance for the votaries of that young Hercules of modern medical birth—State Medicine. Politicians saw in the Report of the Committee on Medical Reform vistas of a warm political discussion; and lovers of a general scrimmage (of which there are always, in a great Association, some active amateurs and many amused spectators) had the prospect of a freely announced "business" debate, which, it was declared, would be decidedly militant. Outside all these extraneous considerations was the fact that the Association, growing annually more numerous and widely spread, is becoming also more united and powerful; and that its annual meetings deal now with questions so large and numerous, and grasp them so firmly and steadily, that its meetings have an importance which cannot but grow. The better part of the anticipations of the meeting have been fully realised; the worse have not. In point of numbers, the assembly will rank among the most numerous on our record. The variety and beauty of the objects of local interest, the warm and anxious desire shown by the resident members of the profession in demonstrating them to their visitors, the general air of holiday and contentment, completed the satisfaction of those who seek relaxation at this as a great professional fête.

The important business of the first night of meeting passed over with what might be characterised as almost uninterrupted harmony; for the dissent from the report and recommendations of the Council and Committee of Council was confined to so few (some half-dozen gentlemen voting against the whole mass of the meeting), that practical unanimity was attained. It is pretty generally understood that the business management should be where the business itself is; and that, as the business lies in London, except at the meetings of the Committee of Council and the annual meetings, the business manager should be there. It was not much to the purpose to remind the Committee of Council that they had not before accepted propositions of reform; for no such proposition as this, which is the evident and essential reform, had ever been placed before them. And, looking to early provincial associations of office, it is unlikely that anything else than a small catastrophe, such as the total neglect of the business of the Association from March 1869 to October 1870, such as Mr. Hodgson described, and the consequent defalcation of an unsupervised clerk, would ever have made acceptable the change now proposed. Acceptable, how-

ever, it proved to be; and it was carried by an overwhelming majority. The subsequent proceedings were characterised by something more than mere harmony—a general desire to recognise every kind of merit, and to do justice to good qualities and good services, too apt to be forgotten in periods of temporary eclipse. In this course all parties agreed; and in this unanimous agreement to forget unpleasant facts in the past, to remember only what it is useful to remember, and to profit by them in the future, there may be seen the happiest augury for the future conduct of affairs.

The first night passed—and passed so happily—the rest of the meeting went merrily as marriage-bells. Two excellent Addresses; compliments from the Corporations; sectional meetings, not overloaded with papers or audiences, but still, well attended; general compliments; fine weather; sea-excursions; the *Agincourt*, with its broken plates and its crest fallen; the turret-ship; reviews; visits to Dartmoor, to Torquay, and a round through notable points of Cornwall in view,—these were more than enough to furnish forth a physical and intellectual feast. The business of the meeting is still progressing; and, thanks to the exertions of Mr. Whipple, Mr. May, the Mayor of Devonport, Dr. Littleton, Dr. Hogarth Clay, Mr. Swain, Dr. John Rolston, Dr. Row, and others whose names we shall be enabled to give in further detail next week, the accessory arrangements of the meeting have been carried out in laborious detail to a point of great excellence, and there is every reason to anticipate that the meeting will terminate without any kind of drawback to mar its perfect success.

### CHOLERA AND THE TYNE.

THE several authorities for administering the Nuisance Removal Acts on the Tyne have held a meeting at Newcastle, and have decided to act together for the purpose of carrying out the recent Order of Council, made with the view of preventing the introduction of cholera into this country, as will be seen from the following resolutions, which were passed at that meeting.

1. That in the opinion of the meeting an inspection should be made of vessels arriving from suspected ports, and that one or more medical officers, with such assistance as may be requisite, should be appointed to act in conjunction with the officers of Her Majesty's Customs.
2. That a floating hospital should be at once provided for the reception of all cases of cholera occurring afloat.
3. That application be made to the Tyne Improvement Commissioners to lay down, in the Narrows, moorings for infected vessels and the floating hospital.
4. That all necessary steps be taken, and requisite assistance and appliances provided, for carrying out the preceding resolutions and the disinfecting of vessels.
5. That the expenses to be incurred along the whole course of the river, with reference to cases occurring afloat, should, in whatever nuisance authority they may arise, be defrayed by the contribution of every nuisance authority on the banks of the river in proportion to the rateable value of each district.
6. That a Committee, consisting of the Mayors of Newcastle, Gateshead, Tynemouth, and South Shields; the Collectors of Her Majesty's Customs at Newcastle, Tynemouth, and South Shields; the Deputy Master of the Trinity House; the Chairmen of the different local authorities; three members of the Newcastle Corporation, and one from each of the other boroughs, with the different Town Clerks and Clerks of Local Boards, be appointed such Committee, and that they be requested to appoint sub-working Committees to carry out the preceding resolutions.
7. That the meeting be adjourned until the 10th day of August instant, at two o'clock, and that the different local authorities be then prepared with the names of the persons to represent them respectively, and with their written assent to the mode in which the expenses are proposed to be defrayed.

MR. THOMAS COOKE has, by a large majority, been elected Assistant-Surgeon to the Westminster Hospital.

It is proposed to establish a cottage hospital at Southend, to cost £800. It is intended to be quite simple and cottage-like.

AMONGST the sixteen Communalist prisoners now being tried at Versailles are M. Rastoul, a physician, and M. Jourde, a medical student.

A STATUE of Sir Humphrey Davy is to be erected in Penzance, the town of his birth. The total cost of the statue will be, it is estimated, about six hundred pounds.

A REMARKABLE case of hydrophobia, in which the symptoms became developed four months after a bite from a dog, proved fatal a few days ago in London. The patient was a girl, ten years of age, and died in University College Hospital.

#### THE NEW BARONET.

THE honour of baronetcy has this week been conferred on James Paget. That distinction has long been anticipated by the unerring verdict of his profession. *Laudatus à laudatis*, Sir James Paget has long held a foremost place in the hearts and minds of his brethren. Many words are out of place; and it is not in a man's lifetime, and, so to say, in his presence, that it is most fitting to say all that is good in him and of him. Gifted with the highest endowments and charms of intellect, his scientific eminence has only made the more remarkable the wide range of virtues and sympathies which adorn his character.

#### THE BARNES CONVALESCENT HOSPITAL.

THE foundation-stone of the Barnes Convalescent Hospital at Cheadle was laid on July 28th by the Bishop of Manchester. Mr. Barnes has already given £26,000 towards its erection, and it is probable that a further sum of from two to three thousand pounds will be required before it is completed. It will be an imposing-looking building, with a frontage of 105 yards. A large winter-garden, roofed in with glass, 100 yards long and 70 wide, will occupy the centre, and afford ample light for the side wings. There will be a cubic space of 3,300 feet for each patient. The hospital is eight miles from Manchester, and has an admirable situation upon a sandy soil in one of the prettiest parts of Cheshire.

#### CHOLERA.

ON board three of the steamers from Cronstadt to Hull there have been fatal cases of cholera; but the health of Hull was never better than at the present moment, the death-rate for the fortnight ending on Wednesday being only 18.9 per 1,000 of the population. The Sanitary Committee of the Local Board of Health have taken the most prompt action with a view to prevent any importation of the dreadful malady. The chairman of that committee, Mr. Alderman Mayfield, first heard that cholera had occurred on board a Hull steamer, the *Burgos*, on Friday last. He at once conferred with the Mayor and the Board's Law clerk, and the same day, before the arrival of the new order in Council relating to cholera, he appointed temporarily a medical officer to board every ship arriving from Cronstadt, and put the sanitary inspector in motion, ordering the preparation of the Cholera Hospital—a wooden building, erected when the town was threatened with the cholera in 1866. At a meeting of the Sanitary Committee, held on Wednesday, the chairman's action was approved, and the following among other resolutions carried:—"That the Local Board, as the nuisance authority, hereby directs that the master of every ship arriving within this district from a place infected with the cholera, having on board any person affected with the cholera, or the body of any person dead with the cholera, must anchor at a place in the Hull Roads at a distance of not less than one hundred and fifty yards eastward of the Humber training ship *Southampton*, in order that all persons on board such ship may be examined and certified, as required by the order." The committee next appointed a medical practitioner, Mr. J. F. Holden, to visit each ship arriving from an infected port. A resolution was also passed to circu-

late among shipmasters copies of the Order in Council. It was also resolved that the law clerk write to the admiralty, asking for the loan of an old war vessel, to be fitted up and used as a hospital ship in the Humber. It was further resolved that the surveyor be empowered to take all necessary steps to place the public and private sewers and ditches within the Board's district in a thoroughly sanitary condition. Other resolutions of a like nature were also adopted.

#### THE NEW HALIFAX INFIRMARY.

THE new Infirmary to be erected at Halifax will contain 217 beds when it is fully completed. At present, the portion accommodating eighty-four beds will only be built. The total cost per bed is estimated at £150.

#### ST. MARY'S HOSPITAL MEDICAL SCHOOL, LONDON.

DR. HANDFIELD JONES has been appointed Lecturer on Clinical Medicine, in the place of Dr. Sibson; and Mr. Spencer Smith to the lectureship on Clinical Surgery, vacant by the resignation of Mr. Samuel Lane. Dr. Broadbent has been appointed co-lecturer with Dr. Chambers on the Principles and Practice of Medicine, and Mr. Gascoven co-lecturer on Surgery with Mr. J. R. Lane. Dr. Nunneley has also been appointed Lecturer on Histology and Experimental Physiology.

#### SMALL-POX IN HAMBURG.

THE following particulars with reference to the prevalence of small-pox in Hamburg have appeared in the newspapers there. The particulars are not of the whole place; for, as far as we know, no official returns on the subject have been published. But the accompanying figures are taken, as above stated, from a newspaper which professes to give the number of cases admitted into the General Hospital and into an Infirmary between January and June last: January, cases 311, deaths 7; February, cases 419, deaths 18; March, cases 471, deaths 38; April, cases 601, deaths 39; May, cases 637, deaths 65; June, cases 834, deaths 85; total cases, 3,273; deaths, 252. It is also reported that the deaths from this disease have been very numerous in the State, the numbers being given as follows: January, 62; February, 107; March, 160; April, 226; May, 400; June, 466; total, 1,421. We believe that the population of Hamburg is somewhere about three hundred thousand; so that, if this amount be taken, the death-rate would appear to be something more than four per thousand of the population—an unmistakably high death-rate for six months.

#### THE SMALL-POX AND SUMMARY OF ITS MORTALITY.

THE present epidemic of small-pox, which may be said to have broken out in the last three months of 1870, caused, according to the Registrar General, 1,229 deaths in England and Wales during that quarter. In the first three months of this year they rose to 4,903, and in the quarter ending June last they further increased to 7,012. Of these, 3,241 occurred in the metropolitan division, 1,120 in the north-western counties, and 1,069 in the northern counties; the remaining 1,585 were distributed among the seven other registration divisions. It will thus be seen that the principal centres of infection were the same four that were noticed in the Quarterly Return for the first three months of this year: London, from which the disease spread into the extra-metropolitan portions of Middlesex, Surrey, and Kent, and also into that part of Essex adjoining the east end of London; Liverpool, from which the infection extended to a considerable number of the other towns in the densely populated Lancashire district, including Manchester, Salford, Bolton, and Wigan, and also, but slightly, into Birkenhead. The third principal centre of infection was the coal districts of the north, more notably the towns of Newcastle, Sunderland, Stockton, and Durham. The fourth distinct outbreak was in the mining districts of South Wales. In London, the deaths from small-pox increased from 2,400 in the first, to 3,241 in the second quarter of this year; in Lancashire and Cheshire they declined from 1,224 to 1,120; they rose in Northumberland and Durham from 461 to 1,022; while in South Wales they declined from

207 to 109, although the fatal cases had increased in Swansea. Of the other and smaller outbreaks which cannot be directly traced to any of the above four centres of infection, the following are the most important:—Southampton, where the deaths from small-pox increased from 24 in the first quarter of the year to 229 in the quarter ending June; Weymouth, where from two in the first, they rose to 39 in the second quarter; Falmouth, which showed an increase from 11 to 27; Bridgewater, which showed 12 deaths last quarter; Oswestry, in which 14 deaths occurred last quarter; Stoke-upon-Trent, in which district 103 occurred in the second quarter, against but one in the first quarter; Nuneaton, in which the numbers were respectively 9 and 26; Coventry, which showed 4 and 14; and Great Grimsby, in which the deaths rose from 18 in the first quarter to 164 in the three months ending June last. The three Ridings of Yorkshire, comprising the ninth registration division, with its more than two and three-quarters millions of population, has hitherto comparatively escaped the effects of the present small-pox epidemic; in the first quarter of this year the deaths from this disease in Yorkshire were but 69, while in the three months now under notice they had only increased to 98; of these, 21 occurred in Bentham and 20 in Kirk Leatham sub-districts, the former in the West and the latter in the North Riding.

#### THE CONTAGIOUS DISEASES ACTS.

THE Association for extending these Acts has shown a remarkable—we had almost said a culpable—apathy in the face of coming events, and has by no means risen to the height of the responsibilities which the members assumed before the country when they commenced their proceedings. They have resolved at a recent meeting to postpone the general meeting of the members, which was to have been held when the Report of the Royal Commission appeared, until the publication of the minutes of evidence, of which the subcommittee hopes to lay before the Association, and the public an impartial summary before Parliament reassembles next session. In the meantime, the subcommittee considers that the Association has much cause for congratulation in the result of the inquiry. The modification and extension of the Acts for the purpose of lessening disease, restraining immorality, and for obtaining legal power to remove young girls from a life of sin, which have throughout been the avowed objects of this Association, are, in the main, adopted by the Commission in their Report. This document has been drawn up after an exhaustive inquiry, in which every one who believed he or she had information to give was allowed full liberty of speech and a patient hearing. It is most satisfactory, they observe, to find that not one of the outrages so vividly described by certain opponents of the Acts has been proved to have actually occurred; and that, while disease among the troops quartered outside the districts of the Acts has increased, and not diminished, it has fallen to less than one-half of its old prevalence where the Acts are put in force. It would be still more satisfactory to find the Association intelligently at work to foil the misrepresentations, and, by truthful and intelligent agents capable of speaking on a platform and writing effectively in local prints, counteracting the restless and mischievous misstatements which form part of the ubiquitous system of agitation of the friends of contagion.

#### BRITISH PHARMACEUTICAL CONFERENCE.

THE annual Conference of Pharmacologists was held last week at Edinburgh, just before the meeting of the British Association. Mr. Stoddart presided. There were about a hundred members present. The President's address discussed pharmaceutical progress. Papers were read on Chloral by Mr. Mason, F.C.S. The conclusions were favourable to the general purity of the substance. Mr. Wood made some important remarks. He believed it was the general experience that what caused the principal variation in the chloroform results, was the presence of rather more or rather less water in the sample examined. But in the manufacture of chloral it appeared probable that there were produced, in a greater or less proportion, certain other substances, and that these might remain associated with the chloral in greater or less proportion; and those sub-

stances were likely to exercise very considerable influence on the medicinal properties of the article. The chloroform test, as far as his experience had gone, failed to be of much use in indicating the presence or absence of such substitution products. What was really required was the means of testing chloral so as to recognise their presence. He himself was inclined to regard the boiling point as a more valuable test to apply; though that, unfortunately, was liable to a defect which was probably due to the action of heat on the chloral itself.—Mr. H. C. Baildon read a brief paper recommending a decoction of the bark of *Rhamnus frangula*, or black alder, as a gentle cathartic, calculated to serve as a valuable substitute for senna.—The Conference then adjourned for luncheon.—The Conference resumed at two o'clock.—Communications were read from Mr. C. H. Staples, on "The Compound Iron Mixture of the British Pharmacopoeia"; by Professor Allen, R.C.S., on "The Purity of the Permanganate of Potassium of Pharmacy"; and from Mr. T. B. Groves, F.C.S., on "Solutions". "On the Use of Blistering Flies in Hydrophobia" was the subject of a worthless paper from Mr. Henry Groves, of Florence.

#### MUNIFICENCE.

MR. CHARLES BROOK, of Enderley Hall, Leicestershire, the head of the firm of Messrs. Jonas Brook and Brothers, thread manufacturers, Huddersfield, lately gave to the Trustees of the Infirmary in that town a "convalescent home," which he has erected at a cost of £12,000, and to the endowment fund of which he presented an additional £18,000. The "home" has been built in the midst of a beautiful landscape, and overlooks, not only Messrs. Brook's manufactories (Meltham Mills), but a church, model working-men's dwellings, schools, dining-hall for operatives, and a people's park, all the gifts of Mr. Charles Brook. The donor in person opened the building, and it was the sign for an almost general holiday in the town. In the evening a banquet was given to celebrate the event.

#### NEW SICK ASYLUM FOR EAST LONDON.

ON Friday last, the Poplar and Stepney Sick Asylum, which has been erected under the provisions of the Metropolitan Poor Act (1867) for the accommodation of the sick of the parishes of Poplar, Bromley, Bow, Limehouse, Wapping, Shadwell, and Ratcliff, was opened for the reception of patients. The building, which has been erected on a plot of land opposite the workhouse of the Stepney Union, at Bromley-by-Bow, has been constructed on the pavilion principle, and consists of eight separate blocks, all of which are connected by a corridor 10 feet wide, and upwards of 600 feet long. Though no great architectural effects have been intended, yet a pleasing effect is obtained from the general arrangement of the pavilions, and by judicious variety in the use of the materials, which are Portland stone and brick. The building is certified by the Poor-law Board to contain 572 beds, and the cubic space allotted to each patient varies from 1,000 feet to 1,500 feet. The central block contains the officers' rooms and a chapel, the latter being fitted to seat 100 persons. It has an open timbered roof of pine, with moulded tie beams and curved ribs under the principal rafters meeting in an apex, and the spandrels filled with perforated panels. Eight stained grisaille windows give light to the building. The whole asylum is warmed by hot water coils. The building was erected by Mr. R. Mann, of Kentish-town, at a total cost of £43,000. This amount is defrayed from a loan made by the District Asylum managers, the repayments from the poor-rates of the district being spread over a long series of years.

#### NORMAL AND MORBID ANATOMY OF THE PELVIS.

AMONGST the useful works chalked out by the Obstetrical Society is the collection of specimens of the pelvis (male and female) of the various races, together with, if possible, foetal heads at term; the collection of abnormal female pelvises or casts; the collection of histories, drawings, or photographs and descriptions, of abnormal pelvises, where it is not possible to procure the pelvis themselves or casts. To carry out this work, a "Pelvis Committee" has been appointed. It is suggested that, as the vacation will be scattering the Fellows of the

Society in various directions, they might lend material aid to the Committee, and at the same time attain a pleasant and instructive motive for their wanderings, if they would undertake to visit such collections as may fall in their way, taking notes of the objects of interest they may contain, and opening communications with the authorities with a view to the procuring of casts, photographs, descriptions, etc. Gentlemen about to start on their tours, who may wish to help in this way, are invited to write for instructions and introductions to the Secretaries, Dr. Wiltshire and Dr. Heywood Smith.

## DIARRHOEA IN LONDON.

ACCORDING to the Registrar-General's return for the week ending August 5th, the deaths in London were so many as 350 below the average numbers in the corresponding week of the last ten years. The fatal cases of diarrhoea, which had been 110 and 201 in the two previous weeks, further rose to 225 last week; this number, however, was 72 below the average number from this complaint in the corresponding week of the ten years 1861-70, corrected for increase of population. Of these 225 deaths from diarrhoea last week, 189 were of infants under one year of age. To cholera and choleraic diarrhoea 18 deaths were referred last week, against 9 and 17 in the two previous weeks; three were of adults, and the rest of infants; the adult cases were all certified as "choleraic diarrhoea," of a few days duration. The mean temperature last week was again somewhat below the average, or probably a still larger fatality from diarrhoeal diseases would have been recorded.

## SMALL-POX IN MANCHESTER.

OUR Manchester correspondent sends a short note on two cases of small-pox which terminated fatally last week. The details are, we think, worthy of record. The first case was that of a girl, aged 20, who died in the Manchester Royal Infirmary. She had three well-marked cicatrices from early vaccination, and also three good vesicles of revaccination, which had been performed a fortnight before her admission, with lymph taken from a child. She sank on the sixth day of the eruption. At the *post mortem* examination, all the organs were found to be healthy. The second case occurred at the Small-pox Wards of the Poor-law Guardians in Canal Street, and was under the care of Mr. Westmorland. The patient was a man, aged about 35, who presented no cicatrices of early vaccination. On the fourth day, Mr. Westmorland found him breathing with great difficulty, and on examination, discovered that the dyspnoea was caused by a very great enlargement of the tongue. He freely incised it down each side with the effect of giving temporary relief, but the glossitis, in spite of this, increased, and in the night, while the patient was asleep, the swollen tongue seems to have fallen back upon the larynx, and caused death by suffocation.

## VIVISECTION.

THE Committee on Vivisection of the British Association have reported as follows.

A Committee, consisting of ten individuals, having been appointed at the last meeting of the British Association, held at Liverpool, to consider the subject of physiological experimentation in accordance with a resolution of the General Committee, the following Report was drawn up and signed by seven members of the Committee: 1. No experiment which can be performed under the influence of an anæsthetic ought to be done without it. 2. No painful experiment is justifiable for the mere purpose of illustrating a law or fact already demonstrated; in other words, experimentation without the employment of anæsthetics is not a fitting exhibition for teaching purposes. 3. Whenever, for the investigation of new truth, it is necessary to make a painful experiment, every effort should be made to ensure success, in order that the suffering inflicted may not be wasted. For this reason, no painful experiment ought to be performed by an unskilled person with insufficient instruments and assistance, or in places not suitable to the purpose—that is to say, anywhere except in physiological and pathological laboratories under proper regulations. 4. In the scientific preparation for veterinary practice, operations ought not to be performed upon living animals for the mere purpose of obtaining greater operative dexterity.—Signed by M. A. Thomson, Oxford; John H. Balfour and Arthur Gamgee, Edinburgh;

G. M. Humphrey, Cambridge; William Flower, Royal College of Surgeons, London; J. B. Sanderson, London; George Rolleston, Secretary, Oxford.

## THE ADVANCE OF CHOLERA.

ACCORDING to Dr. Zuelzer, of Berlin, Asiatic cholera has now entered Germany. During the first three days of August, seventeen fatal cases occurred in Königsberg; the first was of a Polish merchant who arrived at Königsberg from Wirballen. In Riga, seventy-five deaths from cholera were reported between the 5th and 22nd of July.

## MEDICAL EXPERTS IN COURTS OF LAW.

WE have received the following from Mr. James Lane and Mr. Arthur Norton, in reply to the communication published last week from Mr. Lawson Tait.

In your last number you have published some remarks by Mr. Lawson Tait, in which he criticises as a "scandal to science" the evidence given by "two London hospital surgeons" on the occasion of a trial which recently took place at the Guildhall for alleged malpraxis by a dentist. We (the surgeons alluded to) are ready to admit that the present method of taking the evidence of medical experts may be open to grave objections; but the facts of the case in question have been entirely misrepresented by Mr. Tait, and, instead of being liable to the interpretation which he has placed upon them, should, in our opinion, rather be quoted as an example of the way in which juries will occasionally return a verdict in direct opposition to the evidence before them and to the most obvious principles of justice. The following are the real facts. In November 1869, the plaintiff, a mate of a vessel, had his second upper molar tooth extracted by a dentist in Liverpool. The dentist heard no more of the matter till *eighteen months afterwards*, when he received a lawyer's letter demanding compensation for injuries alleged to have been done to the patient's jaw, which request not being complied with, an action for damages was brought. The defendant, the dentist, having no recollection whatever of the circumstance or of the individual, and being in complete ignorance of the nature of the alleged injury and of the evidence to be adduced in support of it, applied to us to examine the plaintiff in his behalf. We accordingly met by appointment for this purpose on the morning of the trial, and, after having waited two hours for Mr. Tait, the medical attendant of the plaintiff, were informed, on that gentleman's arrival, that he preferred not to meet us. We therefore examined the man in his absence; but his legal adviser would not permit us to ask any questions. We found that the teeth and apparently a considerable portion of the alveolus of the left upper jaw were wanting; that there was a sinus discharging matter beneath the upper lip; that the hard palate was extremely tender when touched; and, further, *that the nasal septum had fallen in, and the nose was completely flattened*. We learned, as the case went on, that, in addition to a large sequestrum of the alveolus which had been removed, together with the teeth belonging to it, by Mr. Tait, several other pieces of bone had come away through the nose; and that there was still some dead bone remaining. Our evidence was to the effect that it was in the highest degree improbable, if not impossible, that such extensive disease, especially in the direction of the nose, could have been caused by the extraction of a second molar tooth, even if the jaw had been fractured or fissured for three-quarters of an inch in an upward direction from the alveolus of that tooth, as described by Mr. Tait; who, however, did not see the patient till seven months after the occurrence. We stated also that fractures of the superior maxilla in a healthy person commonly united with great facility, and were rarely attended by serious complications; but that appearances precisely similar to those presented by the plaintiff were not unfrequently met with as the result of constitutional disease, and notably of syphilis. We had also no difficulty in controverting, from our own experience, the statement of Mr. Tait that syphilis, though it might affect other portions of the superior maxillary bone, never affected its alveolar process. The case, however, after all, did not turn so much on the medical evidence as on the question whether reasonable care and skill were applied by the dentist in the extraction of the tooth; it being laid down that, unless the contrary could be shown, no after-consequences would entitle the plaintiff to damages. Mr. Tait has told you that the jury immediately found most substantial damages for the plaintiff; but he has not told you that at the close of the plaintiff's case, the judge intimated his opinion that there was no evidence of want of skill or care on the part of the dentist, but allowed the case to proceed, reserving leave to the defendant to move the full court to have a non-suit entered; and, after hearing the defendant's evidence, he summed up very strongly in his favour. There was a pro-

tracted discussion in the jury box before the verdict was given. The case, therefore, is still *sub judice*; and it is not improbable that the verdict may yet be reversed.

We care little for the opinion of Mr. Lawson Tait; but when that self-satisfied gentleman places himself on a high moral and scientific elevation, and serenely sits in judgment in your columns on the conduct of two members of his own profession with whom he has been brought in contact, modestly drawing comparisons in his own favour, we feel impelled to question his title to the position which he has assumed, and to ask what right he has to infer that the evidence given by us in this case was less honest and conscientious than his own. When this self-constituted censor morum talks of our evidence as a "scandal to science", and as an "unfair attempt to damage the cause of a poor man", he must mean, if he means anything, that we perverted the facts or distorted our real opinions in order unworthily to serve the cause of those by whom we had been consulted—an imputation alike offensive and unjustifiable. It is a "scandal", sir, to our profession, when members of it are found ready publicly to fling about against their *confrères* such reckless and unfounded accusations as these.

#### ST. THOMAS'S MEDICAL SCHOOL.

DR. MURCHISON will deliver the lectures on Medicine in conjunction with Dr. Peacock; Dr. John Harley, on Physiology and Practical Physiology, in conjunction with Dr. Ord; and Mr. Francis Mason and Mr. Wagstaffe, on Descriptive Anatomy. The demonstrations on Morbid Anatomy will be given by Dr. Payne.

THE MEDICAL ARRANGEMENTS AT THE CAMP AT SHOEBOURNESS. THE arrangements this year are of a more complete character than on previous occasions. A hospital-tent, to afford accommodation for six patients, with separate surgery and requisites, has been furnished, and attendants have been supplied from the Army Hospital Corps. Mr. Wickham Barnes, 2nd Middlesex Artillery, is Surgeon in charge, assisted by Dr. W. H. Arthur, 1st Sussex Artillery; Mr. Corbet, 2nd Essex Artillery; and Mr. E. F. Willing, 7th Essex Artillery. The sanitary arrangements of the camp are good, and very little illness has appeared.

#### THE NEW BATHS AT UNIVERSITY COLLEGE HOSPITAL.

WE have had the satisfaction of inspecting the new baths at this hospital, which are now verging on completion, and will be opened in a few days. On a previous occasion, we alluded to the arrangements which were being carried out in their construction. The baths are, it will be understood, not by any means exclusively intended for the treatment of cutaneous affections, although, no doubt, Dr. Tilbury Fox will claim for this class of diseases the largest demand on their therapeutical use. There are means afforded, by the medicated, Russian, vapour, douche, and other baths, for the treatment of nervous and pulmonary diseases, acute rheumatism, and other general maladies; and we look forward with interest to the rich therapeutical harvest which will now no doubt be gathered in the treatment of diseases by the physicians and surgeons of the hospital. The very successful completion—indeed, the existence—of the baths is chiefly due to Dr. Tilbury Fox, who has carried out the undertaking with great energy. The well known architectural ability of Mr. Manning in the arrangement and perfecting of detail is fully represented.

#### THE PRIVY COUNCIL AND THE CHOLERA.

THE Privy Council has issued the following orders in accordance with the powers of the Sanitary Acts:—1. No master of any ship in which, during the voyage and before the arrival thereof at any port of the United Kingdom, any person has been attacked with or died of cholera, shall bring his ship into any such port until he has destroyed the clothing and bedding of all persons who shall so have died, or had an attack of cholera on board such vessel during such voyage. 2. In this order, the term "ship" includes vessel or boat. The term "master" includes the officer or person for the time being in charge or command of a ship. The term "cholera" includes cholerae diarrhoea. 3. The terms "clothing and bedding" mean and include all clothing and bedding in actual use, and worn or used by the person attacked as aforesaid, at the time of and during such attack. 4. Every person offending against this order

shall be liable on summary conviction to a penalty not exceeding £10. 5. The Lords Commissioners of Her Majesty's Treasury are to give the necessary directions herein accordingly.

THE BRITISH ASSOCIATION.—The sittings of the British Association terminated on Wednesday. The general Committee has resolved to make application to Government for a grant of £2000 to assist in defraying the expenses of observing the eclipse of the sun, which will take place in December next. The intended observations are to be made in India and Ceylon. The total number of tickets sold for the Edinburgh meeting was 2463, and the money received £2575.

THE office of Medical Officer of Health for Islington has become vacant by the resignation of Dr. Ballard. The salary attached to the office amounts to £300.

## SCOTLAND.

#### CRAIG *versus* JEX BLAKE.

A FUND is being raised by the friends of the Medical Education of Women Society in England and Scotland, for the purpose of defraying the expenses of the late action, in which the pursuer obtained damages of a farthing, while the defendant was saddled with costs to the amount of nearly £900. Professor MacDonald, of St. Andrews, in a letter which appears in the *Scotsman*, proposes that a public testimonial be given to Miss Jex Blake, and intimates a subscription from himself of £5 towards the object.

#### EDINBURGH ANNUAL DINNER OF THE LICENTIATES IN DENTAL SURGERY.

THE annual meeting passed off successfully in the Douglas Hotel; Mr. Robert Hepburn, late President of the Odontological Society of Great Britain, in the chair, supported by Vice-Admiral Sir Edward Belcher, Dr. Richardson, and others.

#### PREPARATIONS FOR CHOLERA.

WE are glad to observe that the local authorities in most of the east coast seaport towns of Scotland are actively engaged in preparing to meet an epidemic of cholera should it appear in their midst. Many of them are erecting hospitals or making arrangements with the infirmary authorities so as to secure efficient and early attention to cases which may occur.

#### MEDICAL SCIENCE.

PROFESSOR HUGHES BENNETT delivered last week a graduation address at the formal "capping" of the graduates of the University of Edinburgh, which, at any other time of less pressure, we should have been disposed to present to our readers *verbatim*. Vigorous, clear, eloquent, and bold, this address defined the position in the State of the physician, and the attitude in science of the biologist; it dealt severely with the intolerant and ignorant pretensions of verbally educated *litterateurs* and dogmatic theologians to sit in judgment on researches and theories on which they were less qualified to judge, by the blankness of their ignorance and the prejudices of their cultivation, than an intelligent savage. Professor Bennett's address was enthusiastically received.

## IRELAND.

#### VISIT OF THE ROYAL FAMILY TO ST. VINCENT'S HOSPITAL, DUBLIN.

ON Thursday, H.R.H. the Prince of Wales, Prince Arthur, Princess Louise, the Marquis of Lorne, and several noblemen in attendance, visited St. Vincent's Hospital. They were received by Cardinal Cullen and other clerical dignitaries, and were then conducted through the various wards by Dr. Mapother, Mr. O'Leary, and Mr. Doherty, the Surgeon-Dentist.

## APOTHECARIES' HALL OF IRELAND.

At the annual meeting of the General Council of the Apothecaries' Hall of Ireland on August 1st, 1871, the following gentlemen were elected as office-bearers for the ensuing year:—*Governor*: R. Montgomery, Esq. *Deputy-Governor*: J. A. Dirham, Esq. *Court of Directors and Examiners*: T. Collins, C. Holmes, A. Harvey, C. H. Leet, C. F. Moore, H. P. Nolan, J. O'Flaherty, E. J. O'Neill, G. B. Owens, John Ryan, James Shad, John Shea, and G. Wyre, Esqrs. *Examiners in Arts*: G. Atkinson, A.M., M.B.Dub., and J. W. Moore, M.D. *Secretary and Representative in the Medical Council of Education*: C. H. Leet, M.D.

## THE BRITISH ASSOCIATION.

THE British Association commenced its annual Session on Wednesday, August 2nd, at Edinburgh. The issue of tickets proceeded apace, and at six o'clock the numbers stood as follows:—Old life members, 200; new life members, 21; old annual members, 273; new annual members, 96; associates, 801; ladies, 688; foreigners, 15—total, 2,094, representing in receipts, £2,164.

Professor Huxley, the retiring President, introduced Sir WILLIAM THOMSON, the President of the year, who delivered the annual address. The following passages are those particularly interesting to our readers.

*Biological Research.*—The essence of science, as is well illustrated by astronomy and cosmical physics, consists of inferring antecedent conditions and anticipating future evolutions from phenomena which have actually come under observation. In biology the difficulties of successfully acting up to this ideal are prodigious. The earnest naturalists of the present day are, however, not appalled or paralysed by them, and are struggling boldly and laboriously to pass out of the mere "natural history stage" of their study, and bring zoology within the range of natural philosophy. A very ancient speculation, still clung to by many naturalists (so much so that I have a choice of modern terms to quote in expressing it), supposes that, under meteorological conditions very different from the present, dead matter may have run together or crystallised or fermented into "germs of life," or "organic cells," or "protoplasm." But science brings a vast mass of inductive evidence against this hypothesis of spontaneous generation, as you have heard from my predecessor in the presidential chair. Careful enough scrutiny has in every case, up to the present day, discovered life as antecedent to life. Dead matter cannot become living without coming under the influence of matter previously alive. This seems to me as sure a teaching of science as the law of gravitation. I utterly repudiate, as opposed to all philosophical uniformitarianism, the assumption of "different meteorological conditions"—that is to say, somewhat different vicissitudes of temperature, pressure, moisture, gaseous atmosphere—to produce or to permit that to take place by force or motion of dead matter alone, which is a direct contravention of what seems to us biological law. I am prepared for the answer, "our code of biological law is an expression of our ignorance as well as of our knowledge." And I say yes: search for spontaneous generation out of inorganic materials; let anyone not satisfied with the purely negative testimony of which we have now so much against it, throw himself into the inquiry. Such investigations as those of Pasteur, Pouchet, and Bastian are among the most interesting and momentous in the whole range of natural history, and their results, whether positive or negative, must richly reward the most careful and laborious experimenting. I confess to being deeply impressed by the evidence put before us by Professor Huxley, and I am ready to adopt, as an article of scientific faith, true through all space and through all time, that life proceeds from life, and from nothing but life.

*Origin of Life on our Globe.*—How, then, did life originate on the earth? Tracing the physical history of the earth backwards, on strict dynamical principles, we are brought to a red-hot melted globe on which no life could exist. Hence when the earth was first fit for life, there was no living thing on it. There were rocks solid and disintegrated, water, air all around, warmed and illuminated by a brilliant sun, ready to become a garden. Did grass and trees and flowers spring into existence, in all the fulness of ripe beauty, by a fiat of creative power? or did vegetation, growing up from seed sown, spread and multiply over the whole earth? Science is bound, by the everlasting law of honour, to face fearlessly every problem which can fairly be presented to it. If a

probable solution, consistent with the ordinary course of nature, can be found, we must not invoke an abnormal act of creative power. When a lava stream flows down the sides of Vesuvius or Etna, it quickly cools and becomes solid; and after a few weeks or years it teems with vegetable and animal life, which for it originated by the transport of seed and ova and by the migration of individual living creatures. When a volcanic island springs up from the sea, and after a few years is found clothed with vegetation, we do not hesitate to assume that seed has been wafted to it through the air, or floated to it on rafts. Is it not possible, and if possible, is it not probable, that the beginning of vegetable life on the earth is to be similarly explained? Every year thousands, probably millions, of fragments of solid matter fallen upon the earth—whence came these fragments? What is the previous history of any one of them? Was it created in the beginning of time an amorphous mass? This idea is so unacceptable that, tacitly or explicitly, all men discard it. It is often assumed that all, and it is certain that some, meteoric stones are fragments which had been broken off from greater masses and launched free into space. It is as sure that collisions must occur between great masses moving through space as it is that ships, steered without intelligence directed to prevent collision, could not cross and recross the Atlantic for thousands of years with immunity from collisions. When two great masses come into collision in space, it is certain that a large part of each is melted; but it seems also quite certain that in many cases a large quantity of *débris* must be shot forth in all directions, much of which may have experienced no greater violence than individual pieces of rock experience in a landslide or in blasting by gunpowder. Should the time when this earth comes into collision with another body, comparable in dimensions to itself, be when it is still clothed, as at present, with vegetation, many great and small fragments carrying seed, and living plants and animals, would undoubtedly be scattered through space. Hence, and because we all confidently believe that there are at present, and have been from time immemorial, many worlds of life besides our own, we must regard it as probable in the highest degree that there are countless seed-bearing meteoric stones moving about through space. If at the present instant no life existed upon this earth, one such stone falling upon it might, by what we blindly call natural causes, lead to its becoming covered with vegetation. I am fully conscious of the many scientific objections which may be urged against this hypothesis, but I believe them to be all answerable. I have already taxed your patience too severely to allow me to think of discussing any of them on the present occasion. The hypothesis that life originated on this earth through moss-grown fragments from the ruins of another world may seem wild and visionary; all I maintain is that it is not unscientific.

*The Darwinian Theory.*—From the earth stocked with such vegetation as it could receive meteorically, to the earth teeming with all the endless variety of plants and animals which now inhabit it, the step is prodigious; yet, according to the doctrine of continuity, most ably laid before the Association by a predecessor in this chair (Mr. Grove), all creatures now living on earth have proceeded by orderly evolution from some such origin. Darwin concludes his great work on *The Origin of Species* with the following words:—"It is interesting to contemplate an entangled bank clothed with many plants of many kinds, with birds singing on the bushes, with various insects flitting about, and with worms crawling through the damp earth, and to reflect that these elaborately constructed forms, so different from each other, and dependent on each other in so complex a manner, have all been produced by laws acting around us. . . . There is grandeur in this view of life with its several powers, having been originally breathed by the Creator into a few forms or into one; and that, whilst this planet has gone cycling on according to the fixed law of gravity, from so simple a beginning endless forms, most beautiful and most wonderful, have been, and are being, evolved." With the feeling expressed in these two sentences, I most cordially sympathise. I have omitted two sentences which come between them, describing briefly the hypothesis of "the origin of species by natural selection," because I have always felt that this hypothesis does not contain the true theory of evolution, if evolution there has been, in biology. Sir John Herschel, in expressing a favourable judgment on the hypothesis of zoological evolution, with, however, some reservation in respect to the origin of man, objected to the doctrine of natural selection, that it was too like the Laputan method of making books, and that it did not sufficiently take into account a continually guiding and controlling intelligence. This seems to me a most valuable and instructive criticism. I feel profoundly convinced that the argument of design has been greatly too much lost sight of in recent zoological speculations. Reaction against the frivolities of teleology, such as are to be found, not rarely, in the notes of the learned commentators on Paley's *Natural Theology*, has, I believe, had a temporary effect in turning attention from the solid and irrefragable argument so well put

forward in that excellent old book. But overpoweringly strong proofs of intelligent and benevolent design lie all round us, and if ever perplexities, whether metaphysical or scientific, turn us away from them for a time, they come back upon us with irresistible force, showing to us through nature the influence of a free will, and teaching us that all living beings depend on one ever-acting Creator and Ruler. [*Applause.*]

**SECTION D. Biology.**—*President*, Professor Allen Thomson, F.R.S. L. and E. *Vice-Presidents*: Professor Wyville Thomson, F.R.S.; Professor W. Turner, F.R.S.E.; Professor Owen, F.R.S.; Professor Huxley, F.R.S.; Dr. Beddoe; Dr. Hughes Bennett; Dr. Carpenter, F.R.S.; Sir W. Jardine, Bart.; Dr. Sharpey, F.R.S. *Secretaries*: Dr. T. R. Frazer, F.R.S.E.; Dr. Arthur Gamgee, F.R.S.E.; E. Ray Lankester, B.A.; Professor Lawson, M.A.; H. T. Stainton, F.R.S.; C. Staniland Wake, Dir. A.I.; Dr. W. Rutherford, F.R.S.E.; Dr. Kelburne King.

The following was the programme for Thursday.

**Department of Anatomy and Physiology.**—*Inaugural Address* by the President. Dr. B. W. Richardson, F.R.S., Report on the Physiological Action of Organic Chemical Compounds. Professor Rolleston, F.R.S., Report of the Committee appointed to consider the subject of Physiological Experimentation. Dr. Arthur Gamgee, F.R.S.E., On the Heat generated in the Blood during the process of Arterialisation. Dr. A. Buchanan, On the Pressure of the Atmosphere as an Auxiliary Force in carrying on the Circulation of the Blood. Dr. John Chiene, An Experimental Inquiry into some of the Results of Inoculation in the Lower Animals. Dr. Marcet, F.R.S., On the Nutrition of the Muscular and Pulmonary Tissue in Health and in Phthisis, with Remarks on the Colloid Condition of Matter. Dr. J. Batty Tuke and Professor Rutherford, On the Morbid Appearances noticed in the Brains of Insane People.

Professor ALLEN THOMSON'S Inaugural Address on Biology was admirable for its completeness and candour; and full of interesting statements and speculations. On the subject of Embiology he was aware that the mere name of development suggests to some ideas of a painful nature as associated with the theory of evolution recently promulgated. To one accustomed during the whole of his career to trace the steps by which every living being, including man himself, passes from the condition of an almost imperceptible germ, through a long series of changes of form and structure into their perfect state, the name of development is rather suggestive of that which seems to be the common history of all living beings; and it is not wonderful, therefore, that such a one should regard with approval the more extended view which supposes a process of development to belong to the whole of nature. How far that principle may be carried, to what point the origin of man or any animal can by facts or reasoning be traced in the long unchronicled history of the world, and whether living beings may arise independently of parents or germs of previously existing organisms, or may spring from the direct combination of the elements of dead matter, are questions upon which we may expect this section may endeavour to guide the hesitating opinion of the time.

On the subject of Histology, he said: I am inclined to regard contractile protoplasm, whether vegetable or animal, as in no instance entirely amorphous or homogenous, but rather as always presenting some minute molecular structure which distinguishes it from parts of glassy clearness. Admitting that the form it assumes is not necessarily that of a regular cell, and may be various and irregular in a few exceptional instances, I am not on that account disposed to give up definite structure as one of the universal characteristics of organisation in living bodies. I would also suggest that the terms formative and nonformative, or some others, should be substituted for those of living and dead, employed by Dr. Beale to distinguish the protoplasm from the cell-wall or its derivation, as those terms are liable to introduce confusion.

Referring, finally, to Spiritualism, he said: I cannot conclude these observations without adverting to one aspect in which it might be thought that biological science has taken a retrograde rather than an advanced position. In this, I do not mean to refer to the special cultivators of biology in its true sense, but to the fact that there appears to have taken place of late a considerable increase in the number of persons who believe, or who imagine that they believe, in the class of phenomena which are now called spiritual, but which have been long known—since the exhibitions of Mesmer, and, indeed, long before his time—under the most varied forms, as liable to occur in persons of an imaginative turn of mind and peculiar nervous susceptibility. It is still more to be deplored that many persons devote a large share of their time to the practice—for it does not deserve the name of study or investigation—of the alleged phenomena, and that a few men of acknowledged reputation in some departments of science have lent their names, and surrendered their judgment, to the countenance and attempted authentication of the foolish dreams of the practitioners of

spiritualism, and similar chimerical hypotheses. The natural tendency to a belief in the marvellous is sufficient to explain the ready acceptance of such views by the ignorant; and it is not improbable that a higher species of similar credulity may frequently act with persons of greater cultivation, if their scientific information has been of a partial kind. It must be admitted, further, that extremely curious and rare, and to those who are not acquainted with nervous phenomena, apparently marvellous phenomena, present themselves in peculiar states of the nervous system—some of which states may be induced through the mind, and may be made more and more liable to recur, and greatly exaggerated by frequent repetition. But making the fullest allowance for all these conditions, it is still surprising that persons, otherwise appearing to be within the bounds of sanity, should entertain a confirmed belief in the possibility of phenomena, which, while they are at variance with the best established physical laws, have never been brought under proof by the evidences of the senses, and are opposed to the dictates of sound judgment. It is so far satisfactory in the interests of true biological science that no man of note can be named from the long list of thoroughly well-informed anatomists and physiologists, who has not treated the belief in the separate existence of powers of animal magnetism and spiritualism as wild speculations, devoid of all foundation in the carefully tested observation of facts. It has been the habit of the votaries of the systems to which I have referred to assert that scientific men have neglected or declined to investigate the phenomena with attention and candour; but nothing can be farther from the truth than this statement. Not to mention the admirable reports of the early French academicians, giving the account of the negative result of an examination of the earlier mesmeric phenomena by men in every way qualified to pronounce judgment on their nature, I am aware that from time to time men of eminence, and fully competent, by their knowledge of biological phenomena, and their skill and accuracy in conducting scientific investigation, have made the most patient and careful examination of the evidence placed before them by the professed believers and practitioners of so-called magnetic, phrenomagnetic, electro-biological, and spiritualistic phenomena; and the result has been uniformly the same in all cases when they were permitted to secure conditions by which the reality of the phenomena, or the justice of their interpretation, could be tested—viz., either that the experiments signally failed to elude the results professed, or that the experimenters were detected in the most shameless and determined impostures. I have myself been fully convinced of this by repeated examinations. But were any guarantee required for the care, soundness, and efficiency of the judgment of men of science on these phenomena and views, I have only to mention, in the first place, the revered name of Faraday, and in the next that of my life-long friend Dr. Sharpey, whose ability and candour none will dispute, and who, I am happy to think, is here among us, ready, from his past experience of such exhibitions, to bear his weighty testimony against all cases of *levitation*, or the like, which may be the last wonder of the day among the mesmeric or spiritual pseudo-physiologists. The phenomena to which I have at present referred, be they false or real, are in great part dependent upon a natural principle of the human mind, placed, as it would appear, in dangerous alliance with certain tendencies of the nervous system. They ought not to be worked upon without the greatest caution, and they can only be fully understood by the accomplished physiologist who is also conversant with psychology. The experience of the last hundred years tends to show that there will always exist a certain number of minds prone to adopt a belief in the marvellous and striking in preference to that which is easily understood and patent to the senses; but it may be confidently expected that the diffusion of a fuller and more accurate knowledge of vital phenomena among the non-scientific classes of the community may lead to a juster appreciation of the phenomena in question, and a reduction of the number among them who are believers in the impossible. As for men of science who persist in submitting to such strange perversion of judgment, we can only hope that the example of their less instructed fellow-countrymen may lead them to allow themselves to be guided more directly by the principles of common sense than by the erratic tendencies of a too servid imagination.

[We are compelled to break off our report here, having occupied so much space with the report of these admirable addresses.]

MALVERN COLLEGE.—On Tuesday, August 1st, was "Speech Day" at this flourishing Institution, and the proceedings went off with unusual *elalut*. There was a very large and fashionable attendance, comprising many of the local families of distinction, and a large gathering of the parents and friends of the pupils. The Head Master, the Rev. Arthur Faber, presided, and was supported by the Lord Bishop of Worcester, the Visitor of the College.

# THIRTY-NINTH ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION.

Held in *PLYMOUTH*, August 8th, 9th, 10th, and 11th, 1871.

THE Thirty-Ninth Annual Meeting of the British Medical Association was held on Tuesday evening last, at the Assembly Rooms, Plymouth. There were nearly three hundred members of the Association present at the gathering. Dr. Charlton of Newcastle, the President, occupied the Chair. The Mayor of Plymouth and the Mayor of Devonport, with the Corporations of those towns, were present, as were the Earl of Mount Edgumbe and other gentlemen of influence in the locality.

On the President taking his seat, the Mayor of Plymouth, amid loud cheers, gave the Association welcome; and the Town Clerk of Plymouth then read the following address.

"To the President and Members of the British Medical Association, —We, the Council of the borough of Plymouth, desire, in the name and on behalf of the burgesses, our constituents, and the inhabitants at large, to offer to you our cordial welcome on the occasion of your visit to this town. It is our privilege on various occasions to offer such a welcome to distinguished guests; but we have never experienced a more real satisfaction than we now enjoy in hailing your arrival among us, and expressing our admiration and respect for the scientific and philanthropic pursuits which form the objects of your Association. The profession to which you have devoted yourselves is distinguished alike by its labours in mitigating the horrors of war, and in assuaging suffering and arresting the progress of disease in its ordinary and epidemic forms. These services to humanity, rendered on the battle-field and in our hospitals and infirmaries, and in the dwellings of our poorer classes, often without regard to personal interests or personal safety, have obtained for you a deservedly large measure of the public gratitude.

"As constituting the Local Board of Health for this district, we feel a peculiar interest in your labours in the cause of sanitary improvement, and we anticipate a valuable addition to our sources of instruction and information in the discussions which will be devoted to this all-important subject.

"We offer you our best wishes for the success of your Association, and our willing co-operation in all that may facilitate your proceedings and render agreeable your visit to this town and its interesting neighbourhood.—ROBERT C. SERPELL, Mayor."

THE MAYOR asked the Association to receive this address as the spontaneous expression of good will of the inhabitants generally, and said they were all deeply sensible of the honour which the Association had conferred in visiting the town. He sincerely trusted that the gentlemen would thoroughly enjoy themselves, for then there was some hope that this would not be their last visit to this spot.

THE PRESIDENT, on behalf of the Association, thanked the Corporation for their kind expressions of good will conveyed in this address, which, he said, was the first of the kind the Association had ever received; and it would not be lightly esteemed, not only by those present, but by those whom they represent. [*Cheers.*] The profession was to some extent isolated from the rest of the world, but its end and aim was the good of mankind, and they were proud indeed when they found their efforts to arrest the progress of maladies appreciated as they had been by the kind words of welcome given that evening. [*Cheers.*] The Association would not, he assured them, readily forget the reception afforded this year.

The Corporation and visitors then retired.

Then PRESIDENT then delivered the following valedictory address.

Gentlemen,—To the retiring President, as the last act of his official life, belongs the duty of introducing his successor in the chair; and it may also be expected that he should give some account of his stewardship during the twelve months that he has occupied the Presidential chair. Contrary to the expectations we indulged in on assuming office at the meeting of Newcastle, the past year, instead of being one of great excitement among those interested in medical legislation, has been singularly barren of incident in regard to that which is, for our profession, the question of questions—the all-important subject of Medical Reform. Twelve months ago we hoped for a session of Parliament in which this subject would have occupied no small portion of the attention of our legislators, and we girded up our loins for the struggle; but the battle came not. We were willing to devote our time and our energies to do

the work of the British Medical Association, had but the opportunity been afforded to us. If the late session of Parliament has been a singularly unproductive one in reference to general questions, how could our legislators be expected to devote much time to medical reform? a subject interesting to, and understood but by, a few, beyond those who, like ourselves, have had a practical experience of its necessity. Moreover, this year Her Majesty's Government declined to bring forward any measure of medical reform, and left this difficult task to the unaided efforts of private members of the House of Commons. Perhaps, after all, this is not to be regretted. Questions of the most important character—questions of the utmost public interest—have been lost sight of amidst the smoke of contending armies, amidst the din of battle resounding from the other side of the channel. We in the mean time have had leisure to marshal our forces, to analyse and to improve upon the measures of reform proposed during the last twelve months; we have had time to marshal our forces and to bring them early to the fight whenever the struggle shall commence. No measure of medical reform, we can boldly say, will ever be acceptable to the profession which does not embrace the two propositions; viz., (1) the one single portal by which all shall enter the medical profession, and (2) the radical and thorough reform of the Medical Council. But it is not for us to enlarge upon this subject; we turn gladly to the pleasing memories of the last meeting at Newcastle; we greet once more the kindly faces which smiled upon us when we accepted the President's office, and we trust those smiles will not be changed to frowns on this the closing evening of our career. The North this day fraternises with the South; the retiring President from Newcastle introduces the President-elect of Plymouth. Of our successor it is needless for us here to speak; he is well known to you all, and especially to the medical practitioners of south-western England. To him we hand over all the bright anticipations we last year indulged in, of leading the van in a good battle for medical reform; to his guidance we commit the President's office in this great Association, with the full assurance that his energy, his hearty English goodwill, and kindness of manner, will make this meeting one of the most successful among the many memorable reunions of the British Medical Association.

THE PRESIDENT-ELECT then, amid loud cheers, took the chair vacated by Dr. Charlton; and, after a few words expressive of the high sense of honour done to him by electing him President, which he regarded as an honour to his district and not to himself alone, he proceeded to read an address, which is published at page 169.

Dr. SIBSON, in rising to propose a vote of thanks to the retiring President, said the Association, having a new President every year—a President who was always a leading man in his neighbourhood, and among the professional brethren with whom he dwelt—came into contact year by year with the representative men in whatever locality it went. The members of the Association last year had an opportunity of meeting at Newcastle, where a hearty and hospitable reception greeted them, and where it had a notable example of the popularity which attended the medical man in the person of Dr. Charlton, who was a noble representative of an English gentleman, and possessed every qualification the profession could desire to find in one of their high calling. It was due to Dr. Charlton that the Association should give him their cordial thanks, and elect him a permanent Vice-President.

Dr. RADCLIFFE HALL warmly seconded the motion, and said that the Association was now handed over to the genial South by the vigorous North. It was due to Dr. Charlton that he should be heartily thanked, and enrolled among the list of permanent Vice-Presidents of the Association. [*Loud cheers.*]

The motion was then put and carried amid renewed cheers.

Dr. CHARLTON thanked the meeting for the kind way in which they had expressed their approbation of what he had done, or rather, he would say, the manner in which they had pardoned him for being able to do so little. That he had been able to do so little was not owing to a want of will to do more, but to a want of opportunity. It was, perhaps, impossible for the Legislature and the medical profession to concentrate their thoughts on the required Medical Bill while the din of battle was heard across the Channel; and at that time it seemed as if men's minds would never settle down again. He trusted that the time of war had passed away for ever, and that the voice of the profession, joined to the voice of the public, would now be heard by the Legislature. [*Cheers.*] The Association had power in urging on legislation, and it had had the power to compel the Government to withdraw its Bill because it did not meet all that was required. The Association and the profession did not want to act against Her Majesty's ministers, whoever they might be; and he hoped that the Association, representing the profession generally, would be able to work in accord with the Government. Again he thanked them, and most sincerely, for their kind words; and he expressed his pleasure at seeing that what

was done at Newcastle, in the way of giving a welcome to the Association, was being done at Plymouth. [*Cheers.*]

The Hastings Medal was then presented to Dr. J. M. Fothergill of Leeds, who on coming forward to the President's table, was greeted with hearty cheers.

The PRESIDENT addressed the recipient of the medal, and said he could personally testify to the value of Dr. Fothergill's views laid down in the essay for which this medal had been awarded; and persons in this town lived to thank Dr. Fothergill, inasmuch as those persons had been rescued from the verge of death. In conclusion, the President hoped that Dr. Fothergill would be long spared to carry on a work of so great service to his fellow-creatures as that which had earned the recognition of the Association.

Dr. FOTHERGILL thanked the President for his kind remarks and the Association for its recognition of his services, and said the high honour done to him was reflected on the Branch he had the honour to represent. [*Cheers.*]

*Report of Council.*—Mr. WATKIN WILLIAMS, General Secretary, read the following report.

"Your Council congratulate the Members of the British Medical Association on meeting together for the first time in the important maritime town of Plymouth. The very cordial invitation received from the three towns, Plymouth, Devonport, and Stonehouse, signed by all the principal medical practitioners, and warmly supported by offers of assistance from the neighbouring nobility, the civil, military, and naval authorities, and the most influential inhabitants, fully justifies the expectation of a very successful meeting. The Council beg sincerely to acknowledge the energetic efforts which have been made to receive the Association, and to render its visit to Plymouth and the associated towns highly gratifying, not only as respects its scientific, but also its social objects.

"At the Annual Meeting in 1870, there were on the list 4,251 members, of whom 65 have died, 94 resigned, and 106 have been removed for non-payment of subscriptions. 411 new members have been elected this year. There are now 4,403 on the books.

"The Treasurer's accounts, audited by Mr. Church and Dr. E. L. Fox, the Auditors appointed at the last Annual Meeting, have been published in the JOURNAL, and are appended to this Report.

"During the past year, several subjects of grave importance have received the earnest and constant attention of the Committee of Council, and the Special Committees of the Association.

"The Reform Committee, appointed at the last Annual Meeting at Newcastle, will present a special report of its proceedings during the past year. This Committee have strictly adhered to the principles enunciated, and repeatedly endorsed, at the General Meetings of the Association. From circumstances which will be detailed in its Report, medical legislation has been found impracticable during the present session of Parliament, but the Committee are of opinion that the field has been cleared for action, and that arrangements have been made which it is hoped will conduce to a settlement of the long-veiled question of medical reform before the next Annual Meeting of the Association.

"The Parliamentary Committee having been reconstituted, in accordance with the instructions of the last General Meeting, have been quietly but effectively discharging their functions during the present session of Parliament, and will present a report of their proceedings.

"The joint Committee on State Medicine will present a report—a report which deals closely with recommendations of the Royal Sanitary Commission, and the principles that should regulate the future sanitary administration of the kingdom, subjects full of interest both to the medical profession and the public; and which will doubtless occupy a prominent place in the deliberations of the meeting.

"The Therapeutical Committee have been at work during the year; they have performed a large number of experiments, and collected much valuable matter, but are not yet prepared to report the result of their labours. Your Council regret that Professor Hughes Bennett will not, in consequence of ill health, be able to attend the Annual Meeting.

"For the very efficient working of the Branches, thanks are due to the Honorary Secretaries of the Branches of the Association.

"Your Council especially thank Dr. J. W. Moore of Dublin, for the very valuable and efficient services he has rendered to the Association as Honorary Secretary for Ireland, especially as he has had to act on his own responsibility, without the aid of a Council.

"Your Council record, with much pleasure, the establishment of a new Branch in South Wales, which promises to bring together the members of the medical profession in that part of the kingdom.

"The mode in which the business of the Association has been carried on, and especially the absence of supervision over the business and monetary transactions of the JOURNAL office, which has now become a

very important department of the Association, has for some time been far from satisfactory. Your Council must here, however, state that neither the late nor the present Editor of the JOURNAL is responsible for the unsatisfactory management of the business of the office. They thoroughly appreciate the efforts which Mr. Hart has made since his re-appointment as Editor to bring about a better management, and the important assistance which he has rendered in ascertaining the defects which prevail, and the changes required for their removal; but they felt that they could not ask him to continue the supervision of the JOURNAL office, which is no part of the duty of an Editor. The Committee of Council, therefore, in November last, appointed a Subcommittee to consider and suggest means for improving the organisation and business-working of the Association. This Subcommittee met in London; and the inquiry having elicited, among other matters, that from want of supervision at the JOURNAL office, the Clerk and Collector had been able to misappropriate a large sum of money, and then abscond, it was determined to report to Committee of Council that the inquiry was a most important one, and that in their opinion a larger Committee should be appointed. The Committee of Council at once decided not to depute the inquiry to a Subcommittee, but to meet in London, and inquire fully into the general management and financial position of the Association.

"The Committee of Council met in London on the 3rd and 4th of last May, and after a full and searching inquiry, which extended over many hours of these days, and receiving every information from the officers of the Association, and the *employés* of the JOURNAL, unanimously passed the following resolution:—'That the management of the Association having been found, on inquiry, to be in an unsatisfactory state, owing chiefly to defective organisation and supervision, it is recommended that for the future the General Secretary should reside in London, and that he shall devote his whole time and attention to the management and work of the Association.'

"Your Council, although fully recognising that the Association owes much to their present Secretary for the energy which he has displayed in increasing the number of its members, are fully convinced that the amount of Association work done at, and the large sums of money passing through, the JOURNAL Office, imperatively demand that the duties of Secretary of the Association, and the management of the office, so interwoven with each other, should be performed by the same officer, who shall be directly responsible to the Committee of Council. When this change has been effected, the list of Members can be accurately kept, and a regular payment of subscriptions ensured by maintaining a correct account of subscriptions received and due, and thus carrying out a systematic application for arrears. The regular circulation of the JOURNAL can also be thus more efficiently maintained, and other irregularities, consequent on the present arrangements, now complained of, removed. Your Council, therefore, recommend that in future the General Secretary shall reside in London, so that, in addition to the duties now required of him, he shall give personal attention to, and be responsible for, the management of the financial and business department of the JOURNAL Office. The President of the Council has, at the request of the Committee of Council, given formal notice of the alterations which may be required in the Laws, if you think proper to adopt the change now proposed in the duties of the General Secretary.

"The annual accounts of your Treasurer, to whom the Association owes so much, have year by year been audited and published in the JOURNAL. From time to time estimated balances have been printed with the Treasurer's accounts; but it was thought desirable by the Committee of Council at their last meeting, in consequence of the defalcations by the Office Clerk and Collector at the JOURNAL Office, that the exact financial position of the Association should be ascertained by an Accountant; such special audit has been made, and a printed copy of the result is now placed in your hands. Although a deficit is there shown, owing chiefly to the misappropriation of monies at the JOURNAL Office, yet this deficit will be wiped off during the present year by the saving to the funds of the Association which will arise from the lower rate of postage for the JOURNAL. Your Council also trust that an improved system of management and a more regular collection of subscriptions will soon place the finances of the Association on a satisfactory footing, especially if Members will assist by a more regular payment of their subscriptions.

"Your Council deeply regret that five distinguished members have severed their connection with the Association. The cause of their retirement is well known to you all, and your Council can only express their hope that ere long they may again be united to the Association.

"Your Council have felt that it has been their duty to refer to unpleasant facts, and to recommend important changes, the allegiance which they owe to the Association, and their deep solicitude for its well-being, having left them no alternative. They are fully persuaded that a body

which has gained so powerful an influence over the profession, and possesses a JOURNAL which is recognised, both at home and abroad, as one of the ablest exponents and representatives of medical science, will suffer no permanent injury from these passing trials, which, rightly improved, will conduce to better management and future prosperity.

*"Hastings Medal for 1870."*—Four essays of very superior merit were received in competition for this medal. The adjudicators, Dr. Charlton, Newcastle-on-Tyne, Dr. Stewart, London, and Dr. A. T. H. Waters, Liverpool, have awarded the medal to Dr. J. M. Fothergill, of Leeds.

*"Hastings Medal for 1871."*—Your Committee regret that only one essay has been received on the very important subject, "The action of Bromide of Potassium," and that the adjudicators, Dr. C. B. Radcliffe, London, Dr. A. Fleming, Birmingham, and Thomas Scattergood, Esq., Leeds, have recommended that the medal should be withheld."

The Treasurer's report was also presented, as follows.

R. W. FALCONER, M.D., Treasurer of the British Medical Association, in account with that Association for the year commencing January 1st, 1870, and ending December 31st, 1870.

R. WILBRAHAM FALCONER, M.D., Treasurer.

We the undersigned, being the auditors appointed to examine the above accounts for the year 1870, have examined the same with the vouchers, and find the whole correct.

EDWARD LONG FOX } Auditors.  
WILLIAM J. CHURCH }

We the undersigned auditors, appointed by a general meeting of the members of the British Medical Association, held at Newcastle-upon-Tyne, in the month of August 1870, having this day examined the General Secretary's cash-books, together with the lists forwarded by the Branch Secretaries, and the counterfoils of the receipts issued, certify the same to be correct, and that we are satisfied with the accounts which have been exhibited to us.

EDWARD LONG FOX } Auditors.  
WILLIAM J. CHURCH }

Bath, March 28th, 1871.

Mr. HUSBAND said that, as President of the Council, he should feel it his duty to make some lengthy remarks upon moving the adoption of the Report. He should do so because, in the sitting of the Committee of Council, it seemed that the President of the Council was shrinking from his duty in not giving more ample details than were offered as a reason for their recommendations in the Report. For thirty years he had not shrunk from his duty to the Association; and he would not shrink from the Committee of Council now when a cloud was passing over it. He would not shrink from telling the Association what was its real position, and he would say that that position was one quite

compatible with a future of success, if the recommendations in the Report were carried. [Cheers.] He need not touch upon that part of the Report which spoke of the pleasure with which the Council met the general body of members; and no words of his could express the deep sense of pleasure they had in meeting. [Cheers.] The Council held that the accounts should be audited by auditors in whom the Association had confidence, and that the Association should know exactly its financial position year by year. If there were anything to be ashamed of in that position, the shame was to those who did not pay their subscriptions. [Cheers.] He expressed his regret that some gentlemen whom the Association valued had resigned for certain reasons; but he said, much as he valued those gentlemen, who were members high in the profession, who had thus left, he valued the consistency of the Association still more; and he maintained that the Association should follow its own views in preference to giving way to the views of others. [Cheers.] He then entered upon the discussion of that part of the Report which some there considered as the most important; namely, that part relative to the changes which the Committee of Council had considered it their duty to suggest should be made relative to the Secretary's position. It was necessary that that question should be considered fairly; and he submitted that the Committee of Council should have the balance of consideration over those gentlemen who, it was no secret to say, had come there, without having borne any of the heat and burden of the day, and would submit views of their own, founded without any knowledge of the actual facts of the case. Now he would lay these facts before the meeting, and leave the members of the Association to judge as to the course to be adopted. In autumn last the Committee of Council had reason to think that the financial and business affairs of the Association were not going on as they should go on. There had been no great complaints, and the Committee of Council had no thought of any defalcations going on, such as those committed by one of their clerks; but, having their attention directed in the autumn to the manner in which the business was carried on, the Committee as early as November appointed a special Committee to report upon the position. The special Committee came to town early in the spring, and they minutely examined the mode in which the business of the Association was conducted, and then, and then only, did they investigate the defalcations reported to them then on the part of the person who carried out the duties of clerk and collector, and next entered into the whole question. The defalcations only have occurred from the absence of supervision by any business officer. The Subcommittee heard enough from every one who aided their inquiries to prove to them that the business of the office was carried on in such a manner that there was no guarantee that this would not again occur if a change were not made. There was not that supervision by a business officer which was necessary for the conduct of an office and accounts. It was not, it should of course be remembered, in any degree whatever the fault either of the past or present Editor of our JOURNAL; and, indeed, we should have been in a far worse position than we are in if it had not been for the able and intelligent interest which Mr. Ernest Hart, the present Editor, has taken in giving, to some extent, some friendly assistance to make up for the personal supervision which the Association should undoubtedly provide. It is no part of an editor's duty to superintend the conduct of the office, as they themselves will tell you. [Hear, hear.] Well, the Subcommittee spent two days in London. Every one in the office who could give any information was examined; and the Committee found, without any doubt whatever—for there was every disposition on their part to lay open the whole mode of conducting business in the JOURNAL Office—that there was no responsible business supervision, and every one wished there should be. The evidence taken was at the disposal of the meeting; but he would not go into that, because of the time it would take up. There was an attempt on the part of some to instil into the minds of members that there was a desire to take the business from the provinces and concentrate it in London. Now, of all the members who were on the Committee, only two were Londoners, and the provincial men were unanimous in recommending the resolution. [Hear, hear.] He quite agreed with those who were of opinion that all wisdom was not centred in London; but it was to be remembered that the Association was a national institution, and whatever means could be taken to carry out the principles of the Association in the best manner should be taken, even though they might clash with certain personal views. [Hear, hear.] He was not going to speak about any of the letters which had appeared, or to touch upon any one's character; but he would say that no gentleman who took the office of Secretary could attend at the same time to a daily practice. The Committee arrived at this conclusion after a full consideration of the whole subject, and without entering upon the narrow question raised about London and the provinces. The Committee did not say a word about where the JOURNAL should be conducted; but they said that wherever the JOURNAL was conducted,

there the Secretary must reside, and give his personal supervision to the business affairs of the office. He must be responsible for the correct list of the members being kept, for the accurate distribution of the JOURNAL, and for the proper return of subscriptions of members. [Hear.] Unless this course was adopted, no guarantee-office would guarantee the Association against loss from defalcations, because these offices say the Association does not exercise any proper supervision over its clerks. The Committee of Council believed that the Association must have a Secretary who was responsible only to the Committee of Council. This Association could not centre in any one man; and what was wanted was a man who could hold his own position, and take the resolutions passed and see them carried out. These were the views of the Committee, and they were the views of men with whom he himself had had the pleasure of working for many years—men who had a knowledge of business as it should be carried out; and, having investigated the affairs of the Association, the adoption of their recommendation would not lead the Association far wrong. [Hear.] The business of the Association could not go on as it had been going; for, under the system hitherto adopted, the Association would be liable to have these losses year by year. They therefore laid before the meeting what should be done; and they left with the meeting the responsibility of saying whether these proposed alterations should be carried out, or whether the evils which had been mentioned should go on unchecked. He hoped he had not wounded the feelings of any one present; but he had felt it his duty, as he ever should while he remained a member of the Association, to adopt the course he considered best, and urge it on the attention of the members without fear or favour. The accounts had been audited by a professional auditor, who had given to the Treasurer a most valuable analytical account; and this showed that, if it had not been for the defalcations of the clerk, the Association would have had money in hand; and the Association would have been in that position even now, if members had fully paid up their subscriptions. [Hear.] It was to be remembered that the JOURNAL cost sixteen or seventeen shillings a year, and was supplied on the faith that the subscriptions would be paid; and when so large an amount of subscriptions were unpaid, the cost was of course greatly increased. These defalcations and these non-payments of subscriptions had made the balance against the Association at this time about £200; but that could be shortly covered. He had gone through the books, and could say that money had been lost through not being collected—[hear]—and by taking better means for collecting the subscriptions—hoping, too, that members would assist in this—[hear]—a better JOURNAL still would be given even than the very excellent medical authority now given, and a bright future would be open to the Association. [Hear.] He moved the adoption of the Report.

Mr. HECKSTALL SMITH seconded the motion, and said that never since he had been connected with the Association, now upwards of the third of a century, had a question of greater importance been presented to the members than the one presented that evening. The matter, however, was a simple one, though the proposition was of primary importance to the existence of the Association. It was said this necessity for a change could not have arisen if the Committee of Council had done their duty in bygone time; but this could only have been done by coming before the Association as they had now come. He owned that he had been disposed to keep the Association provincial in its character as long as it was possible so to keep it; but the Association had carried out its work of elevating the character of the provincial practitioner, and no little part of the improvement there had been was unquestionably due to the Association. [Hear.] The time came when the character of the institution became extended, and it merged into a general Association; and the JOURNAL was necessarily published in London. There was no doubt that the jealousy in the breasts of provincial members prevented the whole of the executive staff being removed at the time to London; and he for one was ready to confess that he was one who supported only the partial removal. What was done when this partial removal was carried out, was responsible for what mischief had occurred. [Hear.] He hoped that the Association would see the necessity for carrying out the views of the Committee of Council; and he appealed to them whether any business could be properly carried on with the Secretary and the books divided by a hundred miles. The Committee were blamed for not bringing this proposal forward before, and they must bear the blame; but it could be seen that this was a matter which required great consideration; and the Committee having given that consideration, now made the recommendation. [Hear.] This was a great crisis, and he urged the meeting to adopt the motion.

Dr. DAVY said he hoped the result of the Committee of Council were the better for the confusion they had made. [Laughter.] He knew many years ago that the Association was getting into a difficulty ["No"] and now the Committee of Council came forward and said it was owing

to the absence of supervision. There had been, without doubt, an absence of due supervision for several years, and not only so, but there had been a defective organisation of the Association so far as the Council was concerned. The speaker proceeded to say that he had made suggestions at previous times, and had been regarded as troublesome, and he had met with reproaches and threats.

Dr. SIBSON challenged the statement as to threats being used, and it was forcibly denied.

Dr. DAVY then proceeded; and he desired to propose some alterations in the report.

Dr. HUSBAND believed that a member could not thus alter the report, and that the proposal was out of order.

Mr. CLAYTON said the Committee of Council had nothing to seek for themselves, and they had done their duty at an amount of self-sacrifice on behalf of the Association, of which few had any conception. [Cheers.] The position of the Committee of Council was valueless without the sympathy of the members of the general body; and he was sure he was speaking the views of his brother members when he said that unless they had the sympathy of their constituents they would willingly resign. [Hear.] The Committee did their duty with a singleness of purpose which could only be accounted for by their love for their noble profession and a desire to promote the interests of the Association. [Cheers.] He had gone through the accounts, and he could say that if the Association was to go on with financial soundness this change proposed must be adopted. [Hear.] There was no doubt that there was not a penny lost (this was proved by the books) except through that clerk, and the loss was one such as often had happened in the best business transactions of the country. The Association would do well to adopt the recommendation of the Committee.

Dr. SIBSON said, while listening to the speeches given there, he could not help feeling that the same object animated all there, and this was that the Association should be managed in the best possible way. [Hear.] He pointed out the vast increase which had been made in the numbers of the Association of late years; and this, he said, occurring rapidly, had thrown a heavy pressure upon the Association for a larger machinery to conduct the business. He urged the members to forget all personality, and to join as one to spread the advantages of the Association, and ensure for it the great future to which it justly aspired. He thought members should remember that they received a quite incomparable and invaluable JOURNAL, which all were delighted to receive, but for which many did not pay; they should use their personal influence to lessen the difficulties of the Committee of Council. It was no question that the Association could not be carried on unless the change now proposed were adopted. He concluded by pointing out that, by an united action, the Association would have the most important influence for the good of the whole community in pressing forward the measures requisite for the health of our population.

Dr. STEELE asked a question on the accounts.

Mr. SAMPSON GAMGEE said it would have afforded him pleasure to have had the report so modified that it could have been passed unanimously; but as it had not been modified, he should oppose it. If the chief magistrate of this town had remained longer, he would have wondered if, after listening to the speeches, it had been doing honour to a body of commercial gentlemen who had been conducting a weekly journal, or a body of gentlemen associated together for the furtherance of science, who had little knowledge of general business. He freely admitted that the Committee of Council had had a hard time of it, but he could not come there without a passing regret that they had resisted in past times all suggestions which would have prevented the present position. The management had been as bad as bad could be, and because it had been bad as bad could be, the manager was to be taken to London, and the Association was to do away with its present professional secretary. It was as necessary now, as at any time in the history of the Association, that there should be provincial independence against the London corporations, who were the stumbling-blocks in the way of medical reform. He spoke further against the motion, and said that what was required to be done was in the way of a direct representation on the Committee of Council. He asked how the Association could ask the Government to give direct representation on the General Medical Council when it had it not in its own body, but had a body such as its General Council, which had three hundred and sixty-three holidays in the year. He spoke of the subsidised JOURNAL, which could not be carried on, he considered, with success, and called upon the meeting to reject the motion.

On the vote being taken, only five hands were held up against the motion. It was therefore carried.

On Wednesday morning the members assembled in the Town Hall, Devonport, when an address of welcome was presented from the Mayor and Corporation of the borough.

It was agreed that Birmingham be the place of meeting in 1872, and that ALFRED BAKER, Esq., be the President-elect.

Mr. WATRIN WILLIAMS was appointed to act as General Secretary till the end of the year, with a salary of £200; and a Committee was appointed to define the duties of the General Secretary, and to take steps for the appointment of one till the next annual meeting.

Dr. GEORGE JOHNSON delivered the Address in Medicine (*see page 171*).

## SPECIAL CORRESPONDENCE.

### BERLIN.

[FROM OUR OWN CORRESPONDENT.]

AT a recent meeting of the Medical Society here, Dr. Liebreich exhibited a rare form of Calculus, which had lately been removed from the bladder by lithotripsy. It was found to consist almost entirely of gall stone, with a very thin coating of uric acid, and must have found its way into its late home either from the intestine or biliary ducts. Through the kindness of the same gentleman, I am enabled to send you a specimen of a very handy form of drug preparation introduced from Sweden. Each of the small gelatine squares contains a quarter of a grain of acetate of morphia; and, as almost every ordinary medicine has been reduced to this most convenient size, the country doctor may now carry an entire Pharmacopœia in an ordinary envelope. I may also mention that Dr. Liebreich has just published the third edition of his work on *Chloral*, in which he has given a most exhaustive report on the literature of the subject, and referred to every paper of importance in English, French, and Italian, as well as German, literature. The great point now to attain is a precise knowledge of those cases in which its therapeutic value is undoubted; and he naturally feels that its reputation is somewhat imperilled by the reckless manner in which it has been occasionally used.

Many interesting cases have been under treatment in the medical *cliniques*. Professor Traube recently directed attention to one of glanders, in which the face was much swollen and deformed from large reddish-black gangrenous patches, whilst the body was studded with pustules, rather smaller than those of variola. Abscesses existed in considerable number—probably depending on capillary embolism—and the pathognomonic yellow discharge from the nose was not wanting to complete the diagnosis. The patient was a groom, and had contracted the disease from horses under his charge—the *materies morbi* being communicable either by abrasion or contact with a mucous surface. Death usually occurs from pulmonary embolism, and this case was no exception to the rule.

At the *clinique* of this morning, we were enabled to examine the now well-known case in which Professor Traube caused the colon to be opened in the right flank for ileus about two years ago. Four months after the operation, natural motions were passed, and the artificial anus is now closed, and all digestive trouble at an end. In the earlier stages, he recommends the use of iced salt water enemata, passed as high up as possible by means of a curved pipe; and the larger the extent of mucous surface affected at once, the greater the chance of exciting the peristaltic action of the intestine. Crude mercury, formerly used to overcome such obstructions, acted not by its mere mechanical force, but by exciting the nerves to stimulate the muscular tissue from the irritation of its weight. In one instance, where this method proved successful after other means had failed, he was enabled to demonstrate that the therapeutic agent had never left the cavity of the stomach, but had probably caused peristaltic movements by travelling down the canal.

In the service of Professor Frerichs, a very instructive series of cases has been under observation, in which acute endocarditis closely simulated intermittent fever. In one of these, the patient had suffered from pneumonia, but was going on well until rigors set in; the temperature suddenly rose, and the fever assumed a truly intermittent type. On this account, as well as the fact that a loud systolic bruit was now audible, acute ulcerative endocarditis was diagnosed, and placed beyond doubt shortly afterwards at the *post mortem* examination, when a large hole was found in the mitral valve, surrounded by fungoid excrescences. In a second, the symptoms became developed in the course of acute rheumatism; and the intermittent character was even more strongly marked, the temperature oscillating from day to day between 100 and 105 deg. On dissection, inflammation of the mitral valve, with warty growths, was observed. It is interesting to note that in this case large doses of quinine were prescribed without the slightest influence on the course of the fever.

The consumption of uncooked meat in Berlin, and its influence on

health, might well repay investigation. "Beefsteak Tartar", or, in other words, a piece of absolutely raw flesh, raw ham, salmon, and herring, are largely consumed, and their effects may be superficially noted. Tape-worm is common, and is found in a considerable proportion of bodies opened in the dead-house; but which variety prevails I am unable to state. The trichina has only been once seen this *semestre*, and that in a dissecting-room subject; but cases of hydatid have not been infrequent. Two of the liver have occurred in the practice of Professor Frerichs, one of which died, whilst the other ruptured close to the navel, and is doing well; one in Professor Traube's wards; two of the brain, exhibited by Professor Virchow in his course of demonstrations; one of the neck, tapped a few days ago by Langenbeck. These facts are rather significant, and the pen and the eloquence of Cobbold may well be directed against such barbarous food as I have alluded to.

It may be interesting to your readers to know that a successful case of ovariectomy has just occurred in the hands of Professor Martin—his first this session, although by no means the first in his experience. The woman has since emerged unscathed from an attack of small-pox.

I may mention that Professor Langenbeck a few days ago, in commenting on a case, expressed himself as strongly opposed to the English notion that rodent ulcer, as it is there called, is not a cancerous disease. He bases his opinion on the numerous instances in which he has seen it affect internal organs after removal. The ulcerative process here involved a considerable portion of the left side of the face, necessitating the removal of the eyelids, eyeball, left side of nose, and cheek. To remedy this frightful deformity, a large flap was dissected from the forehead and applied to the raw surface, and it is hoped that primary union may be obtained.

Intending students at Vienna will be glad to see that Professor Bamberger's appointment has at last been signed by the Emperor.

Berlin, July 30th, 1871.

## REPORTS OF SOCIETIES.

### OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, JULY 5TH, 1871.

J. BRAXTON HICKS, M.D., F.R.S., President, in the Chair.

MR. CURGENVEN exhibited a Knotted Umbilical Cord.

Dr. PROTHEROE SMITH showed a new Expanding Cylindrical Speculum Uteri.

Dr. WHITEHEAD exhibited two instruments for producing Vesication previous to Vaccination—the one with ammonia, the other with boiling water or the flame of a spirit-lamp.

Dr. HEYWOOD SMITH exhibited a Marine Vaginal Irrigator.

Dr. BARNES read a note on the Rupture of an Intraperitoneal Hæmatocele into the Peritoneal Cavity. One case was recorded by Dr. West, and another as having occurred in Seyfert's practice; but the occurrence was very rare.—Dr. PROTHEROE SMITH related three cases, in each of which, after the sudden disappearance of a retro-uterine tumour, severe peritoneal symptoms became developed.

Dr. PLAYFAIR read the particulars of a case of Sudden Death in the Puerperal State. Although no *post mortem* examination was permitted, the symptoms were characteristic of death from pulmonary thrombosis. The patient, when convalescent from her confinement, had a slight attack of pleurisy.—Mr. SCOTT recollected three cases, in each of which, the patients having been previously debilitated by illness, peritonitis supervened, and death occurred suddenly after slight exertion in bed. On *post mortem* examination, a clot was found in the pulmonary artery.—Dr. ROUTH said that the symptoms might have been those of cramp or spasm of the heart.—Dr. WILTSHIRE inquired whether the urine had been examined, seeing how frequently pleurisy was a complication of Bright's disease.

Dr. TILT read a paper on the Diagnosis of the least known varieties of Uterine Inflammation. The author admitted that all the uterine tissues were inflamed in superacute, in acute, and in chronic metritis; and he explained by what signs these three varieties of metritis might be recognised—mentioning that, while the acute variety was very rare, the chronic was a disease of frequent occurrence. Dr. Tilt believed that one of the uterine constituents could not be long inflamed without the adjacent tissues becoming more or less diseased; and that in the cases called internal metritis, or endometritis, because inflammation of the lining membrane of the womb was their leading pathological condition, there was often a thickening of the uterine walls, to be explained by congestion in most cases, and occasionally by inflammation. In the more chronic stages of internal metritis, the uterine walls were said to become thinner, and to be softened by fatty degeneration—a circum-

stance that should teach caution in the use of the uterine sound. The author discussed the symptoms of internal metritis; and he was thereby led to deny that fundal metritis—that is, inflammation of that portion of the endometrium which lies between the insertion of the Fallopian tubes—had any particular symptoms by which it could be distinguished from ordinary cases of internal metritis. Dr. Tilt asked the Fellows to compare Dr. Routh's cases of fundal metritis with those which he had himself published in his work on *Uterine Inflammation*, promising that they would find the same liability to menorrhagia, and to purulent discharges capable of becoming intensely acrid—the same tendency to obstruction to the free exit of the fluid secreted in the body of the womb—the same kind of very acute uterine pain, aggravated by any kind of pressure, whether made by the finger or by the uterine sound, of which Dr. Tilt reprobated the use in acute metritis.—Dr. PLAYFAIR said that grave alterations were very generally present in such portions of the mucous membrane of the uterus as were accessible to sight; and it was reasonable to infer that, by continuity of tissue, similar alterations existed in the more deeply seated portions of the membrane. He believed that all who had tried intrauterine medication in such cases would bear witness to its remarkable curative power. The application was easy, as the os uteri was always morbidly patulous; and one of the first symptoms of improvement was the closure of the os.—Dr. HENRY BENNET said that arrest of uterine irritation was much more frequently the cause of an increased size of the uterus in child-bearing women than actual inflammation. It was also a frequent mechanical cause of uterine displacements and flexions of all kinds. For many years he had carefully weighed the uteri of all the child-bearing women who had died under his care, and found that, in all who presented lesions of the cervix subsequently to parturition, the uterus had not returned to its natural weight. Dr. Bennet thought Dr. Tilt was scarcely warranted in saying that internal metritis in non-parturient women was common. If confounded with inflammation of the mucous membrane lining the cervical cavity, of course it would appear to be common. The principal diagnostic signs of internal metritis in his experience were a patulous state of the os internum, an aggrandised state of the uterine cavity, and a muco-sanguinolent discharge. The inflammation, when it extended to the uterine cavity, seemed to paralyse and relax the cervical muscular fibres which constituted what he had termed the sphincter of the uterine cavity.—Dr. ROUTH said that, in these cases of enlarged uterus with internal metritis, it was the fundal portion which increased. The nervous supply of the fundus uteri derived from the renal plexus, and being indirectly connected with the semilunar ganglia, was *a priori* evidence that more general and severe symptoms might be expected in inflammation of it, than when the body of the uterus only, or the cervix, was attacked. He could not agree with Dr. Bennet that, because disease of the uterus was cured by active measures to the cervix, therefore the disease was in the cervix. Blistering or cauterising the cervix relieved not only the cervix, but the whole organ. The internal os was occasionally liable to severe inflammatory lesions attended with agonising pain; and such cases were, he believed, incurable.—Dr. FORDYCE BARKER (of New York) assented to most of the statements and doctrines in the paper. But, although it was generally believed that acute non-puerperal metritis was a very rare affection, he suggested that cases of sudden suppression of the menses attended with intense uterine pain and other pelvic symptoms, with fever, quick hard pulse, headache, and sometimes more or less cerebral disturbance, were not very rare; and that they really were cases of acute metritis, which terminated frequently by resolution, leaving no permanent lesion of the organ. Dr. Barker could hardly understand the term fundal endometritis. The distinctions between inflammation of the lining membrane of the cervix and that of the body of the uterus could readily be understood, as the histological and physiological differences between the two membranes were now accepted in science; but if the term fundal endometritis implied a difference which could be recognised and required different therapeutical measures from chronic inflammation of other parts of the body of the uterus, he could not as yet comprehend it. He would ask whether pain was not the most fallacious of all symptoms in establishing the existence or the character of uterine disease. Again, as regards the pain produced by the introduction of the sound in the so-called fundal endometritis, was it not the usual fact that, on the first introduction of the sound, when the point reached the fundus, pain, sometimes very severe and persistent, was complained of; while in the same persons a tolerance of the instrument was acquired after it had been used a few times?—Dr. PROTHIERE SMITH recognised the active metritis described by Dr. Barker. Regarding the uterine canal as a whole, consisting of vagina, cervix uteri, body, fundus, and Fallopian tubes, there were, he believed, corresponding differences in the symptoms marking the occurrence of inflammatory and catarrhal affections of these different parts. When the tubes were

primarily affected, the discharge was watery and colourless, and ejected spasmodically with painful expulsive efforts; whilst when the cavity of the fundus and body was attacked, it would be productive of considerable suprapubic pains and irritable bladder, and at first the discharge would be thin, and often tinged with blood. Again, the glairy secretion, tumefaction, and everted uterine lips, marked similar affections of the cervix. Yet all these, if allowed to run their course, soon merged into one disease affecting the entire canal.—Dr. TILT, in reply, said that he could not see how he could express himself more strongly than he had in appreciation of the value of treatment directed to the cervix; but he often found that this was insufficient to cure chronic metritis and internal metritis; and he believed that the future improvement of uterine pathology lay in the study of the inflammatory diseases of the body of the womb. With regard to his dissent from the views entertained by Dr. Routh respecting fundal endometritis, Dr. Tilt said the whole question was now placed before the profession, and he confidently left it to the decision of future observers.

## MEDICAL SOCIETY OF THE COLLEGE OF PHYSICIANS IRELAND.

WEDNESDAY, MAY 17TH, 1871.

SAMUEL GORDON, M.D., Vice-President, in the Chair.

THE SECRETARY read, in the absence of Dr. HAYDEN, a paper on Diaphragmatic Pleurisy, with notes of several cases. In the first of these, the patient was suffering from lumbago, when he suddenly complained of severe pain in the situation of the diaphragm, and his respiration became markedly thoracic. The usual signs of a localised pleuritis were also present. The coexistence of lumbar and of phrenic pain was noteworthy. The second patient suffered from phthisis. A violent darting pain set in in the neighbourhood of the costal cartilages, and the breathing was costal. The symptoms were but slightly lessened by treatment, yet in due time they disappeared spontaneously. In the third case, there were evidences of pneumonia affecting the lower lobe of the right lung. In this situation there was dullness on percussion, but neither crepitus nor *frottement* was remarked. The patient complained of intense pain, which he referred to the right hypochondriac region. In another instance, the chief symptom was a "stabbing" pain shooting from the inferior part of the left side upwards to the tip of the shoulder. The occurrence of a diaphragmatic hernia, of an empyema, and of diaphragmatic pleurisy, might have given rise to the symptoms. Constitutional disturbance was, however, but slight, and the patient did well. Dr. Hayden then reviewed the literature of the subject. He quoted the allusions to the affection made by Corvisart, Abercrombie, Graves, and others. Andral gave as unequivocal symptoms of the disease the setting in of severe pain darting along the false ribs; the costal nature of the respiration; and the occurrence of a peculiar form of orthopnoea. Dr. Hayden mentioned that, in his opinion, the diagnosis of diaphragmatic pleuritis mainly depended on the following considerations: the occurrence of a sudden and severe pain in either hypochondrium; the shallow and thoracic character of the respiration; the absence of febrile symptoms in mild cases, and the appearance of collapse in severe attacks; the displacement of the diaphragm either up or down; and the resistance of the symptoms to active treatment. Dry cupping, however, was often attended with the best results.—The CHAIRMAN referred to the increased difficulty in arriving at a correct diagnosis when the seat of the disease was on the left side. The case might readily be mistaken for one of acute gastritis. He believed that a valuable aid in diagnosis was afforded by watching the results of upward pressure in both cases. Pleuritic pain was relieved in this way, while the gastralgia was increased.—Dr. A. SMITH looked upon some of the cases detailed in Dr. Hayden's paper as being instances of a neuralgic or rheumatic affection of the muscular structures of the diaphragm, closely analogous to lumbago and to pleurodynia, rather than as cases of pleuritis. The absence of constitutional disturbance in many of the patients, and the failure of active treatment supported this view. He was disposed to place reliance (from experience) in the use of aconite, externally as an anodyne liniment, and internally in small and repeated doses of the tincture.

THE SECRETARY (Dr. EAMES) read a communication from Dr. W. J. CARROLL, of Australia, on the Climate of Sydney. In the course of the paper, Dr. Carroll alluded to the comparative immunity from phthisis enjoyed by Sydney as contrasted with Melbourne and other places on the southern coast of Australia. He also spoke of the treatment of that disease by arsenic, and of the favourable results obtained from the production of rapid cinchonism in certain cases of pneumonia.

## OBITUARY.

### JACOB VALE ASBURY, M.R.C.S., L.S.A., OF ENFIELD.

THE late Mr. Jacob Vale Asbury, who died on June 21st, at his residence, Enfield, in the eightieth year of his age, was in early life a student of the Middlesex Hospital, and for seven years the pupil of, and morbid anatomist to, Joshua Brooks, with whom he afterwards continued on terms of intimate friendship. He was apprenticed to Mr. Dewint of Stone, Staffordshire; and his early years were passed in the mining districts of that county, where he gained much experience among the fearful accidents then common in such localities. He became member of the Royal College of Surgeons and licentiate of the Apothecaries' Society in 1816. About 1818, he visited Enfield as medical friend and companion to a gentleman of position in the neighbourhood. In 1820, he married and commenced practice, and shortly became medical officer to the parish. In 1826, he operated successfully in a severe case of distortion in a child aged 9; and received from the more influential inhabitants of Enfield a testimonial in the form of a silver salver. Another memorial record of silver plate bears the following inscription: "Dono dedit Gulielmus Powell Jacobo Vale Asbury, propter artem ejus eximiam quâ in se quâvis in casu inexplugnabili operationem perfect." In 1833, he published a treatise on epidemic cholera. His "cholera tincture" was sent largely to India. The late Charles Lamb, his friend and patient, bears witness to his successful treatment of cholera in a witty acrostic on his name. Jacob Vale Asbury was on terms of intimate friendship with John Abernethy, Tom Hood, Edward Turner Bennett, and others of note and scientific celebrity. His success as a country practitioner was almost beyond precedent, his reputation extending far beyond the limits of his own neighbourhood.

Enfield was in former years the resort of the aristocracy, of whom there were none but sought him as a valued friend and medical adviser. Towards the close of the year 1852, in consequence of the severity of railway accidents, he turned his whole attention towards the construction of machinery to be applied to railway carriages to lessen the force of collision in the event of trains or carriages being brought into undue contact with each other. This machinery was intended to be applied to the bed of each carriage, and also to be introduced into a safety luggage-van or brake, which he named "Asbury's Diasostikon". His patent for these inventions bears date 4th February, 1853.

In earlier years he invented two surgical instruments—one for the puncture of the tympanum, the other for the extraction of fish-hooks. The late Jacob Vale Asbury was for seven years demonstrator of anatomy to Joshua Brooks.

### WILLIAM REYNOLDS, M.R.C.S., WELLINGTON, SOMERSET.

MR. WILLIAM REYNOLDS, who died recently at Appledore, at the age of 50, had been for twenty-five years in extensive practice at Wellington, in Somerset. He was surgeon to the union house at Wellington, and a district medical officer of the union. The duties were performed personally by him, which entailed upon him much physical labour and anxiety.

## MEDICAL NEWS.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At an extraordinary meeting of the College, on Monday, Aug. 7th, the following members were admitted Fellows.

Child, Gilbert William, M.D., Oxford  
Copeman, Edward, M.D., Upper King Street, Norwich  
Drake, Augustus, M.B., Southernhay, Exeter  
Fox, Tilbury, M.D., 43, Sackville Street  
Hensley, Philip John, M.D., 4, Henrietta Street, Cavendish Square  
Hitchman, John, M.D., Mickleover, near Derby  
Leared, Arthur, M.D., 12, Old Burlington Street  
Stevenson, Thomas, M.D., Guy's Hospital  
Williams, Charles Theodore, M.D. Oxon., 78, Park Street, Grosvenor Square

The following gentleman was admitted a Licentiate of the College.  
Noad, Henry Carden, St. George's Hospital

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary examinations, were admitted Licentiates in Midwifery at a meeting of the Board, on July 31st.

Evers, Benjamin, L.R.C.P. Edinburgh, Fulham Road, S.W.  
Mondelet, William Henry, M.D. McGill College, Montreal Emigration Service  
Smith, Eldred Noble, M.R.C.S., Worth, near Crawley, Sussex  
Willis, Julian, M.R.C.S., Great Northern Hospital

The following gentlemen passed the necessary examinations, and received their diplomas in Dental Surgery, at a meeting of the Board, on August 1st.

Gingell, George, Moreton Ongar, Essex  
King, Richard Francis Henry, Newark  
Marsh, Henry, Chester  
Rose, Harry, Albany Street, N.W.  
Stevens, Mordaunt Augustus de Brouquens, M.R.C.S., Paris  
Vasey, Charles Lyon, M.R.C.S., Cavendish Place

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received their certificates to practise, on Thursday, August 3rd, 1871.

Barrow, Frank Edward, Woolwich  
Barrow, Henry John Waller, Woolwich  
Benham, William Thomas, Bristol Royal Infirmary  
Bland, George, Dalston  
Henson, Walter Knowsley, Hull  
Wade, Reginald, Cross, Somerset

The following gentlemen also on the same day passed their first professional examination.

Fairbank, William, St. Bartholomew's Hospital  
Hall, Frank Algernon, St. Bartholomew's Hospital  
Harvey, William, St. Bartholomew's Hospital  
Floyer, B. Bernard, Middlesex Hospital  
Powell, Joshua, University College  
Triggs, John B. B., University College  
Thompson, Francis Henry, St. Thomas's Hospital  
Welchman, Edward, St. Thomas's Hospital  
Vines, Edward Prince, King's College

### MEDICAL VACANCIES.

THE following vacancies are announced:—

BIRMINGHAM, Parish of—Dispenser.  
BOURNEMOUTH GENERAL DISPENSARY—Resident Surgeon.  
DURHAM COUNTY HOSPITAL—Physician.  
EDINBURGH VETERINARY COLLEGE—Professor of Zootomy or Comparative Anatomy; Professor of Cattle Pathology.  
GREAT NORTHERN RAILWAY—Surgeon for the Grantham District.  
HOLBORN UNION—Medical Officer for District No. 1.  
MIDDLESEX HOSPITAL—Physician; Assistant-Surgeon.  
QUEEN'S COLLEGE, Birmingham—Demonstrator of Anatomy.  
QUEEN'S HOSPITAL, Birmingham—Fourth Physician.  
SETTLE UNION, Yorkshire—Medical Officers for the Horton and Settle Districts, and the Workhouse.  
SOUTH WESTERN PROVIDENT DISPENSARY—One Attending Medical Officer.  
UNIVERSITY COLLEGE HOSPITAL—Assistant Physician.  
UNIVERSITY OF DURHAM—Medical Tutor at the Newcastle-upon-Tyne College of Medicine.  
UNST, Shetland—Parochial Medical Officer and Public Vaccinator.

### MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

ALIEN, Marcus, M.R.C.S., L.R.C.P. and L.M., has been appointed Resident Accoucheur to St. Bartholomew's Hospital.  
BARRY, James Bernard, L.K.Q.C.P. Irel., appointed Medical Officer for the Kilbeggan Dispensary District of the Tullamore Union, King's County.  
\*DRINKWATER, William, Esq., appointed Medical Officer to the Bicester District Union.  
FRIER, Dr. Wm., appointed Medical Officer for the Waringstown Dispensary District of the Lurgan Union, co. Armagh.  
LAFAN, Dr. Patrick Michael, appointed Medical Officer for the Killeen Dispensary District of the Dunshaughlin Union, co. Meath.  
MAGRATH, John, Esq., appointed Assistant Resident Medical Officer to the Leeds Public Dispensary.  
MATHEWS, George C., L.R.C.P. Edin., appointed Medical Officer for the Moate Dispensary District of the Athlone Union, co. Westmeath.  
\*THOROWGOOD, John C., M.D., appointed Junior Physician to the West London Hospital, Hammersmith.

### BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication.

#### MARRIAGES.

\*LOWRY, Harvey, M.D., West Malling Place, Kent, to Jane Frend, daughter of the late Captain William TUCKER, R.N., on August 5th.  
\*MILLER, Alexander Gordon, M.D., F.R.C.S.E., Edinburgh, to Jessie, third daughter of the late Captain Alex. Dingwall Fordyce, R.N., of Brucklay and Culsh, on August 2nd.

#### DEATHS.

WRIGHT, E. Welchman, M.D. Ed., at Shipton-on-Stowe, aged 79, on July 22nd.  
FOLEY, John Joseph, Esq., son of \*W. Foley, M.D., Kilrush, on August 1st.

CHARITABLE DONATIONS.—The Worshipful Company of Mercers has contributed fifty guineas to the fund for the completion of the National Sanatorium for Consumption and Diseases of the Chest at Bournemouth. Her Majesty has given £100 towards the same object.

## OPERATION DAYS AT THE HOSPITALS.

**MONDAY** ..... Metropolitan Free, 2 P.M.—St. Mark's, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**TUESDAY** ..... Guy's, 1.30 P.M.—Westminster, 2 P.M.—National Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.

**WEDNESDAY** .. St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**THURSDAY** .... St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.

**FRIDAY** ..... Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic Hospital, 2 P.M.

**SATURDAY** .... St. Thomas's, 9.30 A.M.—St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Lock (Clinical Demonstrations and Operations), 1 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—East London Hospital for Children, 2 P.M.—Hospital for Women, 9.30 A.M.

## NOTICES TO CORRESPONDENTS.

**ALL Letters and Communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen Street, Lincoln's Inn Fields, W.C.**

**CORRESPONDENTS** not answered, are requested to look to the Notices to Correspondents of the following week.

**TO PURCHASERS.**—To insure attention, it is requested that all orders sent to the Office for extra copies of the JOURNAL, be accompanied with *halfpenny* stamps for the amount.

**WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.**

**CORRESPONDENTS**, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

**DR. DYCE DUCKWORTH.**—The paper is in the hands of the printer.

**R. M.**—By application either to the General Secretary or to the Secretary of your Branch.

**NEMO.**—Being registered under the Medical Act in Medicine and Surgery, Nemo can of course recover in both. The Apothecaries' licence has no special privilege in this respect. Those who already hold the diploma of the London College of Surgeons will be admitted to the examination for the licence of the College of Physicians of London, under conditions which may be ascertained by writing to Dr. Putman, the Registrar of the College.

**A MEMBER.**—Birmingham.

**OBSERVER (Harrogate).**—The circular headed "PRO BONO PUBLICO; NO CURE, NO PAY," is one of the most discreditable productions which ever came under our notice. If "T. Clarkson, Surgeon, Darley House, Darley, Ripley, Yorkshire," whose name is signed, be the author of this handbill, and be on the *Medical Register* as "M.R.C.S. England and L.S.A. London," we commend the case to the attention of the Council. This circular involves a scandalous breach of professional propriety and an extreme degradation of the professional character. We have forwarded it to the Secretary of the Royal College of Surgeons.

## FACTORIES AND WORKSHOPS ACTS AMENDMENT BILL.

**SIR,**—Permit me to call your attention, and that of medical men who act as certifying surgeons of factories, to the Factories and Workshops Acts Amendment Bill, which has passed the House of Lords, and was ordered, on July 18th, to be printed by the Commons. Under the 7th Section, no accidents are to be returned by employers, except (A) any accident which causes loss of life, and (B) any accident caused by machinery or by explosion of gas or steam. Upon consideration, certifying surgeons will see how largely this proposed alteration of the law will affect them, and, I will add, prejudicially affect the *working men*. In this district, I know that inquiries into the causes of accidents have been the means of diminishing the numbers of fatal results. I am, etc., T. J. DYKE.

The Hallam, Merthyr Tydfil, August 6th, 1871.

**DR. SAUNDERS'S VERIFICATION PROOF.**—Dr. Sayre, of New York, writes to us from Rome: "With those hundred and forty-one other candidates, I presented myself at the recent Preliminary Examination at the Royal College of Surgeons, and, to my astonishment and regret, am just informed that I have failed in one subject, the remainder being satisfactory." "And that the respective nominated re-examination in all the subjects should I again apply for admission to examination." As the one subject subject is likely to be of the practical importance to me in after life, neither as an assistance in the study of my profession, nor even as a proof of general education, surely it must be unnecessary to commit me, and others similarly situated, to re-examination in all the other subjects, thus not only burdening me further, according to a medical school or hospital for six months, but also preventing me from pursuing my attention to what is surely the valuable and successful pursuit of the gentleman's science I have adopted. I am, etc.,

August 1871. New York.

**NOTICES of Births, Marriages, Deaths, and Appointments, intended for insertion in the JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.**

**DR. VENABLES, DR. C. FOX, DR. T. L. GREEN.**—We fear we shall be unable to use the manuscripts on small-pox referred to.

**DR. HERBERT L. SNOW (Shrewsbury).**—Pulvermacher's chains have been carefully examined by many eminent members of the profession. They furnish a reliable continuous current, and their precise utility remains to be decided in each case by the medical attendant.

## MEDICAL ETIQUETTE.

**SIR,**—Will you kindly give your opinion on the following points, and your advice as to the courtesy to be observed under the circumstances.

1. A practitioner calling at the residence of a lady under the care of another, and leaving his card for the lady's husband.

2. A patient of one practitioner, suddenly seized with illness near the door of another, into whose surgery he is carried: the latter continues to attend the patient without communicating with the regular attendant.

An answer to the above will oblige.

NEMO.

\* \* \* 1. If the call be made merely in discharge of the ordinary courtesies of society, the act is unobjectionable; if with the ulterior object of supplanting the practitioner in attendance, it is wrong.

2. The practitioner into whose hands the patient has fallen ought decidedly to communicate with the regular medical attendant, unless the patient or friends spontaneously express a decided wish to the contrary.

**A MEMBER** of the Yorkshire Branch should communicate with the Honorary Secretary of his Branch, from whom the report is transmitted.

**A. W. (Leicester).**—We will see what can be done, and communicate further with our correspondent. We shall be glad if he will remind us of the circumstances in about a fortnight's time.

## PORTABLE GALVANIC BATTERY.

**SIR,**—A short time before the late war, a new portable galvanic battery, called Gaiffe's, was introduced to this country, and was being sold here: it was sufficiently small to be carried easily in the coat pocket, and was *always ready for use*, without any preparation, the cells being closed so that their contents could not escape. I ordered one, but the war broke out and stopped the supply; and I have been unable as yet to get one. I shall feel obliged if any of the readers of the JOURNAL can tell me where I can obtain one (I do not mind a second-hand one if in perfect condition). I also want to know what is the strength of the current as compared with the ordinary electro-magnet, and whether it would be sufficiently strong for such a case as galvanising the phrenic nerve in threatened death from chloroform. Possibly there may now be a better apparatus; I shall be very glad to hear of any that will fulfil these conditions—viz., smallness, portability, durability, being always ready for use, and being strong enough for resuscitation from threatened death from chloroform. I am, etc., AN ASSOCIATE.

P.S.—What are Emil Stührer's batteries?

**DEATH FROM CHLOROFORM AT ABERDEEN.**—Our correspondent, J. F., will find that if an animal, say a dog, be slowly asphyxiated, both sides of the heart will be found full, the right containing more than the left, simply on account of its greater capacity. The repeated assertions in text-books that in asphyxia the left side of the heart is empty, or nearly so, and the right full, is unfounded in fact. One author has probably accepted the statement as a fact from some previous writer.

**WE** are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The New York Medical Gazette, August 5th; The New York Medical Record, July 27th; The Boston Medical and Surgical Journal, July 27th; The Madras Mail, May 27th; The Shield, August 5th; The Philadelphia Medical Times, July 19th; The Philadelphia Medical Independent, July 22nd; The Birmingham Morning News, August 4th; The Kentish Express and Ashford News, Aug. 5th; Saunders's News-Letter and Daily Advertiser, Aug. and etc.

**COMMUNICATIONS, LETTERS, etc., have been received from:—**

## AN ADDRESS

DELIVERED AT THE OPENING OF

## THE SECTION OF SURGERY,

*At the Annual Meeting of the British Medical Association,  
in Plymouth, August 1871.*

BY JOSEPH MAY, ESQ.,

Mayor of Devonport, and President of the Section.

GENTLEMEN,—I beg to acknowledge the compliment that has been paid me in asking me to take this chair, and to preside over the proceedings of this Section. I must presume that the offer was made to me in recognition of the social position which I occupy by the indulgence of my fellow-townsmen, and not from any claim that I may present to the Association personally. I will not detain you by any lengthened remarks upon the subject of surgery. After the able address that was delivered to us this morning by Dr. Johnson, perhaps it would be better that we should come almost immediately to the actual business of the Section. However, I may observe that, whilst hearing Dr. Johnson this morning remark upon the great changes that had gone on in medicine within the last thirty years, I recalled the fact that I myself was old enough to recollect that within the same period enormous advances have been made in surgery also. I can look back and recognise in my younger days such great names as those of Astley Cooper and Abernethy, besides others with which we are all familiar as being leaders of the profession in their day and generation. If we compare their opinions and their practice with those of the present day, we are at once reminded of the great advance that has been made. It seems as though medicine and surgery have partaken of the great onward progress that is characteristic of other institutions in society. The adoption of the powers of steam and of electricity has given to society at large an impulse which has altogether transformed the face of things. And so by various agencies which have been at work in the past forty years, the sciences of medicine and surgery have been thoroughly metamorphosed. One of the most valuable agencies introduced during that period has been the use of anæsthetics. Their employment was unknown in my younger days, and without them our hands were comparatively tied; but we now see the beneficial influence of chloroform and allied substances in allowing us to undertake operations extending over periods of time which, without the use of such agents, would have been simple acts of cruelty. In the matter of diseases of bones has the influence of that agency been most conspicuously shown. Operations are undertaken in the present day which occupy half-an-hour or even three-quarters, and which would have been impossible before the discovery of these beneficent aids to surgical science. Anæsthetics are indeed the most valuable agency which has been given to the surgery of the present day. The learned professor in medicine to whom we all listened with so much pleasure, spoke to us of the expectant treatment. Now, the expectant treatment of medicine is becoming more and more in vogue, in opposition to what we may call the more heroic treatment of administering large doses of drugs and other violent measures. In surgery it would not do, however, to trust to expectant treatment. Here you require prompt action. The life of the individual depends not upon waiting upon Nature, but upon prompt interference with the mischief which accident has occasioned. Still, though that applies to wounds recently inflicted, there are cases in which the expectant treatment so ably advocated by the professor is of great value in surgery by giving Nature an opportunity of carrying out her sanitary regulations. Great things may be expected when the conservative method of treatment can be followed out so far as the expectant system is of value in surgery. I had hoped this Section would have been favoured with a paper from a gentleman who had the good fortune to be present in France during a part of the late conflict. Circumstances have prevented him from doing so; but as he is present, I have no doubt we shall be favoured with the result of some of the observations which he made during the campaign.

THE PATHOLOGY AND TREATMENT OF  
CHOLERA.\*

By GEORGE JOHNSON, M.D., F.R.C.P.,

Professor of Medicine in King's College, London; Physician to King's College Hospital; etc.

IN the present communication, my object will be to bring distinctly before you, in the fewest possible words, the main points relating to the pathology and treatment of cholera which I hold to be probably true, and upon these points to invite comment and discussion.

Cholera is the result of a material and portable poison, capable of being conveyed from place to place and communicated from person to person. The poison may enter the system either with the air through the lungs, or with the food and drink through the alimentary canal. Water contaminated with choleraic discharges is, in a large proportion of cases, the vehicle by which the poison enters the system. Whatever may be its mode of entrance, the poison is absorbed and enters the blood. When it enters by the lungs, the blood is the only channel through which it can reach the alimentary canal.

The usual period of incubation, *i. e.*, the interval between the reception of the poison and the commencement of the symptoms, varies from one to three or four days. Mr. Macnamara records the fact of nineteen healthy men having, on one occasion only, drunk water with which cholera stools had been mixed. One man was seized with cholera after an interval of one day, two on the second, and two on the third day, after imbibing the poison; the others escaped.

In some cases, a general feeling of *malaise* and depression, the result, probably, of blood-poisoning, precedes the commencement of the gastro-intestinal symptoms. The discharges from the alimentary canal are the result of a conservative effort to expel the poison and its products from the system; in this respect they are analogous to the eruption of small-pox, and the intestinal discharges of enteric fever. The discharges, when abundant, are a source of great exhaustion, and they may be so copious as to kill. That they are not the essential or the chief cause of the state known as cholera collapse is clear from the following considerations. They bear no direct relation to the degree of collapse; often an inverse relation.

Collapse and death may occur without discharges and with but a scanty secretion into the alimentary canal; on the other hand, recovery from collapse is always associated with a continuance of the discharges, which gradually cease as reaction occurs. During the state of collapse, there is evidence of an impeded circulation through the lungs. This is shown—During life, 1. by the comparative emptiness of the systemic arteries, the pulse being small and feeble, or even entirely absent at the wrist. 2. By the fullness of the systemic veins; hence the lividity of the surface. After death, evidence of impeded circulation is found in the condition of the heart and lungs; the left side of the heart is empty; the right side, the pulmonary artery, and the large veins are distended; the lungs are anæmic, light in weight, and either dark- or light-coloured, depending on the presence or absence of a retrograde passive congestion of the *bronchial* veins and capillaries. The only probable explanation of this arrest of the circulation is contraction of the minute pulmonary arteries. A similar arrest of the circulation occurs as a result of acute apnoea. The state of collapse which accompanies a fit of spasmodic asthma is very similar to the collapse of cholera. The main difference between choleraic and asthmatic collapse consists in this—that in asthma there is a primary apnoea, the result of bronchial spasm, and a secondary asphyxia or pulselessness consequent on contraction of the minute pulmonary arteries. On the other hand, in cholera there is a primary asphyxia and a secondary apnoea consequent on the arrest of the circulation.

Embolism of the pulmonary artery has in several recorded instances given rise to the most characteristic symptoms of cholera collapse—blueness of the surface, shrinking of the features, pulselessness, coldness of the tongue and breath, urgent dyspnoea, with loud puerile respiration over the lungs and a feeble whispering voice.

Feebleness of the heart does not explain the arrest of the circulation in cholera. Why should the right heart alone be always enfeebled? And, admitting weakness of the right heart, this would not explain the fact that, while the blood has been abruptly stopped just before reaching the capillaries, the trunk of the pulmonary artery is so distended that, when its walls are punctured soon after death, the blood spurts out with considerable force—showing that, while the right ventricle

\* Read before the Medical Section at the Annual Meeting of the British Medical Association, in Plymouth, August 1871.

had continued to contract, some obstacle in front had prevented the onward movement of the blood.

There probably is some weakening of the heart's walls during collapse, in consequence of the defective circulation through the coronary, as through all the systemic arteries. This weakness of the heart's walls is obviously a consequence, and not the cause, of the impeded circulation through the lungs. The dark and viscid condition of the blood is a result of the defective aëration and movement of the blood. The same condition of blood occurs in all forms of apnoea. So long as the circulation and respiration are free, mere loss of water does not thicken the blood, for the reason that water is rapidly absorbed from the soft tissues throughout the body to supply the place of that which is lost by vomiting and purging. After the discharges have ceased, this borrowed water has to be restored to the tissues, and the urine remains suppressed or scanty until the loan has been repaid.

The greatly diminished, almost suspended secretion of bile and urinary solids during collapse is explained by the defective circulation, and the consequent diminished oxidation of blood and tissues. Bile, urine, and carbonic acid, are joint products of oxidation. In a nursing mother who is the subject of cholera and collapse, the secretion of milk continues, because the milk-constituents—casein, sugar, oil, and water—are not oxidised products. The marvellous temporary relief which follows the injection of a warm saline solution into the veins during collapse is due partly to the morbid blood being diluted, and thereby rendered less obnoxious to the resisting arterioles, but mainly to the relaxation of the arterial spasm by the high temperature of the injected liquid. It has been found by those who have had most experience of this method of treatment, that hot injections are more efficacious than those of lower temperature.

In the treatment of cholera and choleraic diarrhoea, which is, in fact, cholera in a mild form, the main principle to bear in mind is, that the discharges are as essentially curative as is the eruption of small-pox. The discharges are not to be abruptly stopped by opiates. Experience has abundantly proved that this is a pernicious practice. Neither are they to be permitted to accumulate in the alimentary canal. There is one remedy which is almost universally applicable in all forms and stages of the disease, and that is an abundant supply of cold water to flush the intestinal sewer, and to wash out the poisonous discharges. A copious imbibition of pure cold water will suffice for the cure of most curable cases.

Palpation and percussion of the abdomen reveal the fact that there occurs not unfrequently a painful and sometimes a paralyzing over-distension of the bowel by rapidly effused morbid secretion. This, if not promptly relieved, may even go to the extent of causing a fatal obstruction. More especially is this likely to happen when the sensibility of the bowel has been deadened by opium. The plan to prevent and to remove this accumulation is to give some quickly acting yet unirritating evacuant dose. For this purpose, castor-oil is, on the whole, better suited than any other remedy. The objection sometimes raised—that all remedies must be useless, because none are absorbed—obviously does not apply to such a remedy as castor-oil, which, by its merely local action upon the mucous surface, stimulates the bowel to expel its contents. Experience has amply proved the success of the treatment in this and kindred classes of cases.\*

The time to give opium, if at all, is in small doses to soothe the bowel after the expulsion of the poisonous secretions. Opiates are useless, and even dangerous, when the blood is poisoned, or when the bowels continue to secrete offensive morbid secretions. Opiates in the early stages of diarrhoea and cholera would be more frequently and decidedly injurious, were it not for the fact that their absorption is prevented by the rapid current of liquid which is being poured from the blood into the alimentary canal; therefore they are quickly expelled, together with the morbid secretions, and they are powerless to arrest the discharges.

## INTEMPERANCE AND CHOLERA.†

By ROBERT MARTIN, M.D., Manchester.

WE are assured, on tolerably good authority, that the terrible destroyer, cholera, which has already again and again ravaged this country, is once more marching towards our shores. Now, forewarned by, or should be, forewarned, and many members of our profession have done the state good service by pointing out what are the weak parts in our sanitary defences, and showing us which of these the enemy's assault is most likely to be made. It may seem somewhat premature to treat and engraven

to say that in the letters and leading articles which have lately appeared, it is doubtful whether the greatest source of the nation's peril has not been entirely overlooked. So far as I am aware, no writer has ever alluded to intemperance as a powerful predisposing cause of cholera, yet it is certain that, both directly and indirectly, it tends to promote the occurrence, spread, and fatality of zymotic disease in its most malignant form. Now that, in the enumeration of preventable causes, this should be overlooked, would be most unfortunate. Thousands may strike on this unbuoyed rock, on which thousands have already struck and been wrecked. It will be comparatively useless to lavish large sums of money on sanitary operations, the erection of hospitals, the appointment of trained nurses, if an agent so directly provocative of zymotic disease, is allowed to operate unchecked.

The better to comprehend the bearings of this question, it will be well to give a passing glance at the sequelæ of intemperance.

1. *Indigence*.—The intemperate man burns the candle at both ends, he wastes time during which the means of providing for his family should be earned, and he squanders much of the little which he has earned. He is, therefore, miserably poor; he and his family suffer frequently from lack of food, and that which they do get is often bad in quality. It is for this class that the stink butchers—the dealers in diseased flesh-meat and tainted fish—chiefly cater. The half-famished are glad to seize on any garbage whereby the pangs of hunger may be appeased.

2. *Overcrowding* is another of the conditions most frequently associated with cholera outbreaks, where persons are found huddling together, purity of air, cleanliness of person, are all but impossible, it is in the drunkard's lair that we find this evil most strongly marked. He cannot, or will not, pay for a decent lodging, his family have to take refuge wherever they can, often in foul damp apartments. Again, not only does overcrowding favour the outbreak of epidemic disease, but more than anything else it tends to promote its spread. Until men, women, and children live like human beings, instead of herding like pigs in close pent up styes, they will be liable to be ravaged by epidemics. Until families are located in roomy dwellings, where each individual can have something like the cubical space which we give to convicts or paupers, we shall be kept in a state of alarm, shall be disgraced by the outbreaks of pestilence—amongst the surest indications of residuary barbarism. It is well-known that animal poisons are intensified by concentration. Hence, as regards effluvia, the law may be thus expressed:—As the square of the distance separating those infected diminishes, so the infecting power of the poison increases. So long as people are crowded into filthy apartments, it will be impossible for the sanitary authorities to stamp out pestilence. But if roomy dwellings are to be provided they must be paid for, but if people are to be in a position to pay they must be industrious and sober; they must also be orderly in their conduct and careful in their treatment of property. Whilst vast numbers of the working classes are addicted to habits of drunkenness they will not pay rent, their brawls and midnight revels drive away respectable tenants, the children of the drunkard are frequently recklessly destructive of property. Hence capitalists will not build cottage property, and those who possess it are glad to turn it into workshops or stables, etc., or pull it down and appropriate the ground to some other purpose. If drunkenness were less rife amongst the working classes, dwellings would be as freely provided for them as well as for the class above them. For a variety of reasons, therefore, overcrowding must be chiefly debited to intemperance.

3. *Filth* is another agent strongly favouring the development and spread of cholera. But filth is too often a direct result of intemperance. The drunkard's wife is too often a spirit-broken creature, lacking food, enduring cruelty, obliged to nurse sickly children, or having to struggle to maintain them; who can wonder that she is slatternly and dirty in her home? Is it reasonable to expect women to keep their families and homes cleanly who return at night, fagged with a day's washing or hawking, or factory or field labour, to which she is driven through the idleness of a drunken husband? But in the lowest deep there is a lower deep, when the wife and mother is herself a drunkard. An example of this was presented lately in the case of the family at Ilford, where a man was found on the floor in one apartment who had been dead a week, whilst his wife lay drunk in the next room amidst filth and stench which were sickening. Now drunkenness amongst females is terribly on the increase. A more humiliating confession, or a more ominous one, could not be made. Liverpool is the most unhealthy town in the kingdom, and in no part does female drunkenness so greatly abound or increase so fast.

But it is the poisonous effects of alcoholic liquors which most directly open the doors for pestilence to enter. The depression which follows the free use of liquor, the loss of functional balance, the retention of effete matters, the enfeebled circulation, the torpid liver, and weakened

\* See a valuable paper by Dr. McClelland and Robinson, *Med. Chir. Trans.*, vol. 56.

† Read before the Medical Section at the Annual Meeting of the British Medical Association, at Plymouth, August 1871.

digestion, the generally lowered tone of the system, all favour the development of zymotic agents.

During the cholera-visitation of 1832, the nurses in the Manchester Cholera Hospital were at first allowed to go home each day at certain intervals. This arrangement gave them the benefit of a certain amount of out-door exercise and change of atmosphere, as well as relieved the tedium of their duties; the mortality, however, amongst them was so great that it was feared that the supply would fail. It was discovered that, with the idea of protecting themselves against the disease, they indulged freely in liquors; they were therefore confined to the hospital, and debarred from obtaining more than a small allowance of alcoholic drink, after which not a single fresh case occurred amongst them. Here we see that, notwithstanding far less favourable hygienic conditions, there was an immunity from cholera attacks when there was a greatly diminished consumption of alcohol.

Cheerfulness is undoubtedly one of the best defences against cholera, as depression is one of its most effective allies. Nevertheless, joyousness associated with the free use of liquors, as is so frequently the case in this country, may be productive of very adverse results. When the cholera-visitation of Glasgow (1832) was dying out, the jubilee was held to celebrate the passing of the Reform Bill. This gave rise to a considerable increase of drinking and drunkenness; the result was that cholera, which was nearly extinct, burst forth afresh, causing considerably increased mortality.

During the second epidemic, a great increase in the number of deaths from cholera took place during and after the New Year's festivities. At Gateshead, the week after Christmas-day was signalised by a most terrible fatality, which was obviously attributable to the drunkenness which prevailed in the town; one of the worst streets of which was said to be swept of confirmed drunkards from one end to the other, with very few exceptions.

At the close of the cholera-visitation, as experienced in Liverpool in 1866, Dr. Shearer, in his Report to the Toxteth Park Board of Guardians, thus wrote:—

"Of all the physical causes predisposing to cholera, indulgence in intoxicating liquors is the most powerful. This was proved on a large scale by the number of applications on the Sundays, Mondays, and Tuesdays, being from seventy to a hundred daily in excess of the number of applications on other days of the week. I have no hesitation whatever in tracing this terribly significant fact to the drunken orgies of Saturday night, Sunday, and Monday, which follow the weekly receipt of wages on the part of the labouring community."

The cholera-attack on the metropolis told, in 1866, with terrible effect on the East of London, more especially over the Limehouse and Ratcliffe districts. Mr. Orton, the Medical Officer of Health, in his report, states: "Those who have been water-drinkers, teetotallers more especially, have been pre-eminently exempt." Again, in his report for the year ending Lady-day 1867, after an enumeration of the facts connected with the outbreak, he declares: "That the drinkers of stimulating liquors, both fermented and spirituous, all other conditions being equal, were pre-eminently the sufferers and victims during and arising from the epidemic."
